In the United States, previous to 1881, one or two small plants had attempted to use pyrites, practically all manufacturers using brimstone. At that time the Albert mine, at Capelton, Canada, was acquired by Geo. H. Nichols and Company—later the Nichols Chemical Company. From that time on, pyrites mines were discovered and worked in Virginia, Massachusetts, Newfoundland, Canada, Georgia, and elsewhere, and the European pyrites were imported, until to-day the amount of brimstone used for producing burner gas in the sulphuric acid industry is practically nothing.

Between 1881 and 1891 reliable statistics are not available, but in 1892—in addition to the domestic production in Virginia and Massachusetts, and zinc blende used by Messrs. Mathiessen and Hegeler, at Lassalle, Ill.—upwards of 135,000 tons of pyrites were imported into the United States for the production of burner gas, whilst last year 566,000 long tons were imported, in addition to an estimated domestic production of over 200,000 tons, and a much extended use of zinc blende.

The penalty of increased cost of plant and process costs attached to the use of pyrites has not prevented its practically universal adoption by the sulphuric acid industry, and it is only reasonable to suppose therefore that there must be some predominant advantage in the use of pyrites, at any rate in the sulphuric acid industry.

The manufacture of sulphite pulp is of much more recent inception than that of sulphuric acid. At first many difficulties were experienced in its manufacture, and as its price was relatively high, the cost of a small item of raw material entering into its manufacture was inconsiderable, and naturally the purest, least troublesome, and most available material was adopted. The quantity of sulphur used, compared to the tonnage of sulphite pulp, is comparatively small, averaging probably considerably less than 300 lb. to the ton of pulp, whilst in sulphuric acid manufacture, sulphur constitutes about one-third of the weight of acid, or about 670 lb. to the ton. As in all new industries, however, after the first monopoly is broken and competition begins to be felt, lower production cost becomes necessary. This is already resulting in the substitution of a burner gas made from pyrites or other metallic sulphide in Germany, Norway, and Europe generally—a substitution which is rapidly becoming complete.

In the United States, the industry, whilst very great, is still more recent than in Europe. It is only within the last few years that American sulphite pulp manufacturers have learnt to use brimstone successfully. Some sporadic attempts have already been made here to substitute pyrites for brimstone, but no general move has as yet been made in this direction, although strangely enough, it is true that the success of this substitution in Europe is largely due to the employment of American apparatus (Herreshoff and O'Brien furnaces, &c.).

One reason which has retarded the use of pyrites by

the sulphite pulp manufacturers is that too much has been expected. It is useless to expect to obtain the same burner gas when using pyrites as has been obtained when using brimstone. The volume of pyrites burner gas will always be at least one-third greater than that of brimstone burner gas, and certain modifications in the acid plant will become necessary. As, however, the volume of the gas greatly decreases by proper cooling, and the velocity of its absorption is at the same time greatly increased, much may be done by securing a more efficient cooling of the gas. At 0° C., 1000 cb. ft. of 12 per cent. burner gas made from pyrites would contain as much sulphur dioxide as 1000 cb. ft. of 16 per cent. burner gas made from brimstone at 100° C. A more expensive equipment for roasting the pyrites and purifying the gas must also be faced. The matter is not one of inventing new processes and apparatus. Burner gas from pyrites up to 12 per cent., and pure gas, to a degree of purity far and away beyond that required in pulp manufacture, has already been obtained and is in commercial use both by acid and pulp makers.

In short, it may be definitely stated that the question is no longer a technical one, it is simply and purely a financial proposition.

Can pyrites be obtained, and a suitable burner gas be produced and used in making sulphite pulp, at a cost sufficiently less than the brimstone burner gas to provide—first, for the interest and amortisation on the additional capital investment; second, for the increased manufacturing cost; and, third, to provide a sufficiently attractive margin of profit or a sufficiently lower manufacturing cost per ton of pulp to justify the larger investment and the trouble involved in the deviation from established methods?

Whilst it is difficult to submit cost figures which will apply to every case, I think that the following figures are reasonably conservative when applied to many New England localities, and, at any rate, may form a basis upon which more accurate calculations may be made for any given locality. It is assumed that the best of each class is used, and in the case of brimstone, that such a quality is supplied, that 99 per cent. of its weight will be recoverable as sulphur dioxide, and that pyrites will be used which will yield 40 per cent. by weight of sulphur as sulphur dioxide. Fines or granular pyrites are assumed, as it is only by the combustion of "fines" pyrites in MacDougall type furnaces, that strong gas can be secured.

The cost of such a quality of brimstone and of the very best quality of "fines" pyrites, delivered *ex* ship at Atlantic port, would to-day be respectively about 22.00 dols. and 6.00 dols. per long ton. To this price must be added 0.25 dols. per ton for the cost of unloading at factory, sampling and assaying. The cost of handling and roasting will vary with the quantities handled, and the character of the equipment at any factory. When the quantities handled are about equivalent to 7·5 tons of actual sulphur in 24 hours, it may be said that brimstone should not cost over 40 cents per ton and pyrites not over 50 cents per ton, including repairs and incidentals. Should the factory be located away from tide water, railway freight would have to be added. The equivalent of a freight of 2.00 dols. per ton on pyrites, would be 2.75 dols. per ton of brimstone. We have, therefore, the following costs of delivering and handling our raw materials:—Brimstone: Atlantic port, 22.65 dols. per long ton; inland, 25.40 dols.; pyrites, Atlantic port, 6.75 dols.; inland, 8.75 dols. per long ton.

Therefore 1 ton (2000 lb.) of sulphur will be equivalent to 1·01 ton of 99 per cent. brimstone, and 2·143 tons of 49 per cent. pyrites; hence the cost of one short ton of sulphur at Atlantic port as brimstone will be 20.43 dols., and as pyrites, 12.92 dols. At inland factory as brimstone, 22.91 dols.; and as pyrites, 16.74 dols.

Take the case of a factory at the seaboard and inland respectively as above, using 7·5 tons of sulphur daily, or 2,700 tons yearly. If this sulphur is supplied as brimstone it would cost 55.161 dols. seaboard, and 61.857 dols. inland. If it were supplied as pyrites it would cost 34.884 dols. seaboard, and 45.198 dols. inland; leaving a difference of cost in favour of pyrites of 20.277 dols. seaboard, and 16.659 dols inland.

As the plant for roasting pyrites and purifying the gas would cost at a liberal estimate about 30,000 dols. for a plant of this capacity; 12 per cent. may be written off for interest and amortisation, which would leave the net difference some 3,600 dols. less, or 16,677 dols. seaboard, and 13,059 dols. inland, which would represent the net saving or cheapening of the manufacturing cost of the pulp. This should amount to from 75 cents to 1.00 dol. per ton of pulp; and with care and the purchase of a cheaper pyrites may be considerably more.

I believe these figures are conservative. They will undoubtedly vary according to the locality, conditions at any given plant, and the skill used in making the change: in operating, in purchasing supplies, and, in short, with the excellence of the individual management.

In the sulphuric acid industry, it is a very common statement, that, before a change from pyrites to brimstone could be considered, brimstone would have to be sold at from 12.00 dols. to 14.00 dols. per ton, according to the location of the factory.

Imported pyrites can be obtained in the open market at varying prices according to the quality, and on contracts extending from one year up. All such imported pyrites can be used for producing a burner gas suitable for sulphite pulp making, but some of them will require a rather more costly purifying plant than others. It would be well, therefore, to construct a purifying plant, capable of treating the more impure gases from the cheaper pyrites; and in this way to be in a position to burn any ore which could be obtained to best advantage. Imported pyrites are brought principally from Spain, Portugal and Newfoundland. Pyrites is also produced in Massachusetts, and a company of undoubted financial standing has been for some time developing, and is now about to put on the market high grade "fines" of a great purity, mined in St. Lawrence County, New York. Other local deposits will undoubtedly be developed if stimulated by a local demand. The copper-bearing pyrites of New Hampshire, Maine, Vermont, and other New England States will also ultimately form a valuable source of supply.

Discussion.

Mr. F. G. Stantial inquired about the percentage of sulphuric anhydride in burner gas.

Dr. F. H. Thorp asked if arsenic had any injurious action other than the objection of having it present in the pulp on account of its poisonous character.

Mr. Falding said, that with proper regulation of draught it was possible to keep down the percentage of sulphuric acid to a mere trace, much less than was usually present in gases from brimstone burned in a large excess of oxygen. The poisonous nature of arsenic was the objection to its presence in pulp.

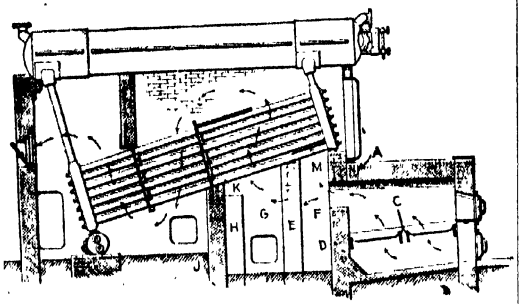
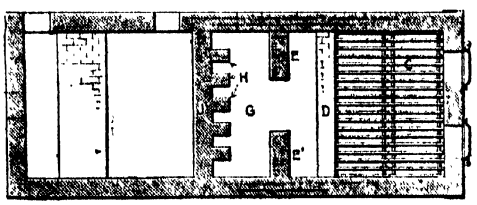
DR. RUSSELL W. MOORE IN THE CHAIR.



A PRACTICAL WAY OF BUILDING SMOKELESS FURNACES.



BY ERNEST H. FOSTER.

A vast number of devices for preventing smoke are successful in so far as they accomplish the desired result, but either they are too expensive, or they occupy too much space, require too much attention, deteriorate in certain parts, curtail the capacity of the furnace, or require conditions which do not exist in ordinary plants

To be practicable, a furnace must not only provide such nearly perfect conditions of combustion that smoke will not be formed, but the construction must be so simple, that it can be built without difficulty and without employing experts, and the working conditions must be such as not to unduly tax the average fireman. These results would seem to have been accomplished by the Wing Wall Furnace invented by Prof. Wm. Kent, and applied successfully to a fair number of boilers up to the present time. This furnace is suitable for either a water-tube or fire-tube boiler, and is designed to provide the essential features required for perfect combustion in the furnace, such as heat-retaining masses of refractory material in the path of the gases and means for intermingling the products of combustion from various parts of the grate.

The furnace consists of an arch, A, over the grate, C, (see Figs.), a pair of "wing walls," E, E¹, or piers built

out from the side walls of the setting, and a number of brick piers, H, H, H, in the combustion chamber, G, so disposed as to present as much incandescent surface as possible to the gases of combustion in passing. The arch over the fire and these two wing walls form the chief features of this furnace. The products of combustion on leaving the grate pass over the bridge wall, D, in a wide horizontal stream. These will vary in temperature at different points. Where fresh coal has been thrown on the grate the gases will be distilled in greater volume and will be insufficiently supplied with air. This is where the smoke is formed, whereas from the portion of the grate which has been previously coaled the fire will be burned out and the bed of coals porous, the gases will not only be smokeless but will be incandescently hot and will have a surplus of air. Unimpeded, these gases would pass through the boiler in this state and never mix. In this furnace, however, the space between the two wing walls is of such a form as to divert the stream of gases from a horizontal plane into a vertical plane, thereby mixing the cool, freshly-distilled hydrocarbon gases with the hot incandescent products of combustion, allowing the surplus of air from one portion to make up for the deficiency of the other portion. The conditions requisite for perfect combustion have therefore been produced, and when the gases have passed between the wing walls and are ready to enter the boiler flues they have been thoroughly burned and are free from smoke. To get the best results out of this furnace the foreman has only to feed coal to the grate at regular periods, alternating between the two sides.

In making the application to a water-tube boiler of the Babcock and Wilcox type, the furnace is usually built out in front like a Dutch oven, whereas with the horizontal tubular or Heine type of boiler the furnace need not extend beyond the boiler setting. It must not be thought that the interposition of the arch under the boiler shell will cut down the heating surface of the boiler. A small portion of the heated gases does pass between the shell and the arch. The cooling effect of the shell serves to preserve the arch, while the arch in its turn protects the shell at this point and the boiler receives as much heat at this point as the shell is capable of transmitting in any event.

It will be seen that the construction of this furnace can be easily handled by an ordinary mason or boilersetter. The walls will be of ordinary fire brick, except the wing walls, which, if made up with the best grade of fire brick, will last a very long time. It is only necessary, in making the design, to so properly proportion the various passages as not to choke the gases and so restrict the capacity of the furnace. The saving by using Wing Wall Furnaces instead of a common furnace will be from 5 to 10 per cent with the best bituminous coal, such as Pocahontas, Cumberland or Clearfield, and will be from 10 to 15 per cent. with Pittsburgh and Ohio coals, and 15 to 20 per cent. with Illinois coal.

MR. J. M. C. PATON IN THE CHAIR.

THE BACTERIOLOGICAL TESTING OF DISINFECTANTS.

BY T. H. LLOYD.

The relative values of disinfectants are usually based on the amount of active principle contained in them. This method of examination is correct when the preparations owe their activity to their amount of chlorine, available oxygen, &c., but where organic compounds are concerned, deductions based on analytical percentages are usually far from the truth, as the substances with which they are associated have a deciding influence on their behaviour as germicides. The aromatic series of organic compounds is largely called upon to supply the wants of the manufacturer, and differences in the constitution of nearly-related families are sometimes taken advantage of in the production of their specialities. Such differences are sometimes small and obscure, and need a large amount of research and time to reveal them. The organic principles employed are usually associated with glue, resins, hydrocarbons and other substances, any one of which may have been selected for some particular property which it possesses, and a statement of analysis which shows percentages of phenols, hydrocarbons, resin acids, alkali, &c., gives no data of value. The physical condition in which the disinfectant is to be used, too, is a point of considerable importance, as it has been repeatedly found that an emulsifying preparation, containing one third the amount of active agents of a solution, is much the more powerful germicide. Chemical methods are of great service in foretelling the suitability of a given bactericide for a particular purpose. For instance, chlorine or ozone might be recommended for the sterilisation of water which contained little organic matter, but they would not be suggested for the disinfection of fluids heavily charged with organic impurities such as sewage. The use of the salts of copper, mercury, or of many of the heavy metals which form compounds with albumin, would not be suggested for use in its presence, as their usefulness would be greatly restricted by it. Great service has also been rendered in the classification of compounds having antiseptic and germicidal properties, but beyond the limits thus briefly sketched, chemistry does not go in the deciding of the efficiency of disinfectants.

Bacteriological methods.—Until recently, the want of uniformity in the conditions under which disinfectants were tested, led to the utmost confusion as to their capabilities and great conflict of opinion among observers working on the same substance. Many attempts were made to lay down standard conditions for all workers, but without much success, until the Rideal-Walker method was published.* These observers pointed out that the following factors were to be reckoned with before the desired uniformity could be obtained:—(1) Time; (2) age of culture; (3) choice of medium; (4) temperature of incubation; (5) temperature of medication; (6) variation in vital resistance of the same species; (7) variation in the resistance of different species; (8) the proportion of culture to disinfectant.

The introduction by them of pure phenol as a standard control solved the whole of these factors, and as the method has been adopted by the War Office, the Admiralty and other public bodies, I give it as it was originally published:—

"To 5 c.c. of a disinfectant, add five drops of a 24-hour old blood-heat culture of the organism in broth, shake, and take sub-cultures every 2½ minutes up to 15 minutes. Incubate these sub-cultures at 37° C. for at least 48 hours. Allowing 30 seconds for each act of medication, and the same time for making each sub-culture, four dilutions of the disinfectant under examination, together with one standard control, may be tested against the same culture under conditions which make the results strictly comparable.

"When a dilution of the disinfectant is obtained, which does the same work as the standard carbolic acid dilution, the former is divided by the latter, and the ratio so obtained is termed the carbolic acid co-efficient."

The temperature at which tests are carried out is from 15° to 18° C., as this is found the easiest to maintain in a laboratory all the year round. Good relative values are usually obtained in the hands of any one worker, if the conditions described are observed, but it is unfortunate that a large number of workers on the same organism and the same samples show a good deal of variation as far as the co-efficients found are concerned. This points to the existence of a disturbing factor or factors which the authors have either not taken into account or omitted to mention. The following is an illustration of the variability of co-efficients and the general constancy of relative values. Some time ago I determined the values of two coal-tar preparations which were somewhat similar in constitution. They were then sent to other analysts—six in all—who, with one exception, used the method as described. The relative values found by five of us were in fair agreement, but in no two cases were the co-efficients alike. They varied from 5·5 to 9·3. These differences were very striking; but had one sample only been examined by all of us, they would have been still more confusing, as it would not have been shown that the factor or factors affecting the results were constant for any one observer. Repeated examinations by several of us yielded the same result. Inquiry showed that in some cases distilled water was used for dilution of the samples, and in others, tap water; whilst, in one case, an agar culture replaced the prescribed broth culture.

On learning these facts, I started some experiments in the hope of clearing up these discrepancies. They were as follows:—

The action of distilled water for dilution was compared with that of a moderately hard tap water. The effect of a filtered and unfiltered agar culture on the co-efficients was tested. The effect of filtration of broth cultures, together with a determination of any difference which might arise if the unfiltered broth culture were shaken immediately before some of it was removed for the medication of the dilute disinfectant. So as to make the conditions of experiment as nearly alike as possible, they were carried out at a temperature of from 56° to 58° F., as this was found to be the most convenient. The same saponaceous emulsifying preparation was used in all cases; the same platinum wire was used for taking sub-cultures throughout, the size of the loop being 3 mm. in diameter. The broth was as constant as possible in composition, and was made as follows:—10 grms. of Lemco were dissolved in 1000 c.c. of water. To this were added 10 grms. of Witte's peptone and 5 grms. of common salt. After boiling for half an hour, the broth was made neutral to phenolphthalein with normal sodium hydroxide solution; 15 c.c. of normal hydrochloric acid was then added. After boiling for 30 minutes, the broth was filtered, allowed to cool, made up to 1000 c.c., filled into tubes and sterilised. The same strain of *B. typhosus* was also used for all the observations; the cultures used for the tests were of uniform age, *viz.*, 24 hours old. In each case the culture was shaken and allowed to stand for 20 minutes (so as to permit the clumps to settle) before any of it was withdrawn for the tests.

Distilled water.—Table 1 shows the co-efficient obtained with freshly made emulsions, and Table 2 shows the figures obtained when the emulsions had stood for seven days, the solutions being shaken just before use.

TABLE 1.

Sample.	Dilution.	Time culture exposed to action of disinfectant. Minutes.					
		2½	5	7½	10	12½	15
Disinfectant + ...	1: 880	+	—	—	—	—	—
"	1: 990	+	+	—	—	—	—
"	1:1100	+	+	+	—	—	—
"	1:1210	+	+	+	+	—	—
Carbolic	1: 110	+	+	+	—	—	—

Carbolic acid co-efficient, $\frac{1100}{110} = 10$. Sub-cultures: Period of incubation, 72 hours; temperature, 37·5° C.*

TABLE 2.

Sample.	Dilution.	Time culture exposed to action of disinfectant. Minutes.					
		2½	5	7½	10	12½	15
Disinfectant + ...	1: 660	+	—	—	—	—	—
"	1: 770	+	+	—	—	—	—
"	1: 880	+	+	+	—	—	—
"	1: 990	+	+	+	+	+	—
Carbolic	1: 110	+	+	+	+	—	—

Carbolic acid co-efficient between 8 and 9. Sub-cultures: Period of incubation, 72 hours; temperature, 37·5° C.

* In these tables, + indicates growth; — no growth.

Tap water.—Table 3 shows this had the effect of reducing the germicidal value of the sample somewhat as compared with the distilled water, even when the solutions were fresh.

TABLE 3.

Sample.	Dilution.	Time culture exposed to action of disinfectant. Minutes.					
		2½	5	7½	10	12½	15
Disinfectant + ...	1: 880	+	+	—	—	—	—
"	1: 990	+	+	+	—	—	—
"	1:1100	+	+	+	+	—	—
"	1:1210	+	+	+	+	+	—
Carbolic	1: 110	+	+	+	—	—	—

Carbolic acid co-efficient, 110—9. Sub-cultures: Period of incubation, 72 hours; temperature, 37·5° C.

Table 4 shows that when the emulsions were allowed to stand for seven days there was a drop in the co-efficient of over 50 per cent. Considerable separation had taken place, and the globules which had settled out could not be got back into a state of perfect emulsion when the containing flask was violently shaken. I may here state that I have observed the same effect of tap water on a non-saponaceous emulsifying preparation; in fact, all the emulsions I have examined in this way show a falling off more or less great.

TABLE 4.

Sample.	Dilution.	Time culture exposed to action of disinfectant. Minutes.					
		2½	5	7½	10	12½	15
Disinfectant + ...	1: 660	+	+	+	+	—	—
"	1: 770	+	+	+	+	+	+

"	1: 990	+	+	+	+	+	+
Carbolic	1: 110	+	+	+	—	—	—

Carbolic acid co-efficient, about 6. Sub-cultures: Period of incubation, 72 hours; temperature, 37·5° C.

Agar cultures—Filtered and unfiltered.—Freshly made dilutions of the fluid under examination were made for this test with distilled water. A 24-hour old blood heat slope culture was taken and to it was added 2 c.c. of sterile distiled water. The tube was then shaken until the growth was entirely removed. The resulting emulsion of organisms was not allowed to settle. It was added to the dilutions of disinfectant in the ordinary way. The result is very striking, the co-efficient being nearly halved, as a glance at Table 5 will show. A microscopic examination by means of a hanging drop of the emulsified culture showed that it was largely composed of clumps of the bacilli.

TABLE 5.

Sample.	Dilution.	Time culture exposed to action of disinfectant. Minutes.					
		2½	5	7½	10	12½	15
Disinfectant + ...	1: 500	+	+	+	—	—	—
"	1: 600	+	+	+	+	+	—
"	1: 700	+	+	+	+	+	+
"	1: 800	+	+	+	+	+	+
Carbolic	1: 110	+	+	+	+	—	—

Carbolic acid co-efficient, between 5 and 6. Sub-cultures; Period of incubation, 76 hours; temperature, 37·5° C.

Table 6 shows the co-efficient obtained when these clumps are removed by filtration.

TABLE 6.

Sample.	Dilution.	Time culture exposed to action of disinfectant. Minutes.					
		2½	5	7½	10	12½	15
Disinfectant + ...	1: 880	+	—	—	—	—	—
"	1: 990	+	—	—	—	—	—
"	1:1100	+	+	—	—	—	—
"	1:1210	+	+	—	—	—	—
Carbolic	1: 120	+	+	+	—	—	—

Carbolic acid co-efficient, over 10. Sub-cultures: Period of incubation, 76 hours; temperature, 37·5° C.

Filtered broth culture.—The co-efficient for this is identical with that obtained on an unfiltered culture which has been allowed to stand. See Table 7.

TABLE 7.

Sample.	Dilution.	Time culture exposed to action of disinfectant. Minutes.					
		2½	5	7½	10	12½	15
Disinfectant + ...	1: 880	—	—	—	—	—	—
"	1: 990	+	—	—	—	—	—
"	1:1100	+	+	—	—	—	—
"	1:1210	+	+	+	—	—	—
Carbolic	1: 110	+	+	—	—	—	—

Carbolic acid co-efficient, $\frac{1100}{110} = 10$. Sub-cultures: Period of incubation, 76 hours; temperature, 37·5° C.

A glance at Table 8 reveals the fact that the co-efficient is slightly lowered if the culture is constantly shaken before some of it is withdrawn for the tests.

TABLE 8.

Sample.	Dilution.	Time culture exposed to action of disinfectant. Minutes.

"	1:1100	+	+	+	+	+	—
Carbolic	1: 110	+	+	+	—	—	—

Sub-cultures: Period of incubation, 76 hours; temperature, 37·5° C.

The foregoing experiments appear to indicate that, to secure greater concordance in results, less latitude should be allowed to the individual operator, and since it is desirable that this be remedied, it should be directed, first, that distilled water only should be used for dilution; second, that agar cultures should be abandoned in favour of broth, and that the broth cultures should be filtered through ordinary filter paper so as to remove clumps. It should also be made imperative that the carbolic acid used should be standardised by bromine titration, as the pure crystals on the market contain varying amounts of moisture—sometimes as much as 8 per cent. The authors of the method recommended that carbolic acid of the B.P. should be used as it was supposed to be uniform in composition, containing 100 parts of phenol in 110 parts. My experience of it is that it shows considerable variation. It is very evident that accurate work is out of the question if the disinfectants are to be put into competition with a variable standard.

Another point which calls for consideration is the composition of the broth used. I have had long experience with the one just described, and I have found it to give the most uniform results. When meat is used instead of Lemco, the composition of the broth is variable. The acidity of meats varies very considerably, therefore varying amounts of soda salts are formed on neutralisation. Undoubtedly the vital resistance of an organism depends very greatly upon the medium in which it is grown, and should this vary from day to day, trouble will be experienced, as the dilution of carbolic acid necessary for killing it will be anything but constant.

The method just described may be objected to on account of the fact that the conditions of experiment are far removed from those which obtain in practice, but I submit that most of the standard laboratory methods we are accustomed to are open to the same objection. Yet none would discard them on this account since the indications which they afford are of great value. It has been shown that the test can be modified to meet any individual requirements. For instance, the compatibility of a disinfectant with soap may be tested by diluting it with a standard soap solution. The effect of organic matter on its utility may also be tested by the introduction of solutions of organic matter such as albumin and urine, but the conditions

under which these modifications are carried out must be standard.

The Sanitary Institute has appointed a strong committee to consider the question of standardisation of disinfectants, and Colonel Firth and Prof. MacFadyen, who have directed the work found necessary for its deliberations, have reported in favour of the "drop method," as devised by Rideal and Walker. The report, together with a very large amount of the experimental work done, is contained in the February number of the Journal of the Royal Sanitary Institute. They have recommended that the garnet and thread tests be discarded, as they are too elaborate and unreliable. They have also put forward for consideration a modification of the Rideal-Walker test which was devised by Major Fowler. The single organism is here replaced by a mixture of urine and fæces. It is described in the report above referred to, and also in an article by Major Fowler himself, which appeared in the January number of the Journal of the Royal Army Medical Corps. The mixture is prepared as follows:—1 grm. of fresh fæces is rubbed up in a mortar with 100 c.c. of freshly passed urine. The resulting emulsion is filtered through an ordinary filter paper to remove lumps. Three c.c. of the filtrate are then added to 3 c.c. of the disinfectant solution it is required to examine. The subsequent procedure is then similar to that already described. The sub-culture tubes must be examined at the end of 24 hours and any growth in them then is regarded as *B. coli*. As the *B. coli* is somewhat more resistant than the *B. typhosus*, it is assumed that any of these which may be present are killed off if the readings show negative. The main difficulty with this method is the inconstancy of the composition of the material to be examined, and also the variability of the forms of bacteria present. Sporogenous forms, though not of much importance from the pathogenic point of view, are likely sometimes to make the results obscure. I have had some experience with the method and obtained results which are not strictly concordant with one another; still, I think that where any doubt exists as to the behaviour of the disinfectants in the presence of fæces, indications of great value can be got by it. Some of the co-efficients obtained by Major Fowler are very interesting when they are compared with those obtained on the single organism, as they show that many of the highly prized disinfectants of the past, are, in the presence of the mixture, very much affected in activity.

Discussion.

Mr. J. H. Worrall said he still held that the bacteriological examination of disinfectants was a very marked advance upon the hitherto unsatisfactory methods of chemical analysis. Since Rideal and Walker's paper was read, many observers had carefully watched the progress of their method. A unit or so of difference in the carbolic acid co-efficient obtained by different workers upon the same disinfectant might be allowed, but when two bacteriologists of repute reported 2 and 15 respectively as the co-efficients for the same disinfectant on the same germ, the failure of the practical carrying out of the method must be acknowledged. It was unfortunate that tenders should be asked by sanitary authorities in terms of the Rideal-Walker method until at least uniform results could be obtained by separate investigators. But supposing this method were perfect in its working, what could be said respecting the great differences obtained when using the same disinfectant upon different germs? These differences had been attributed to selective action. The disinfecting value of mercuric chloride as found upon the *B. typhosus* would fail when used for treating an open wound contaminated with the *M. pyogenes aureus*. The Rideal-Walker method professed to measure only one property of a disinfectant. There were, however, several other properties of very great importance, *e.g.*, the permanence of disinfecting-action. Then there was the power of discrimination between germs and innocuous organic matter. The permanganates did not discriminate, and consequently their value, determined upon germs in presence of little organic matter, gave no measure of their actual value when used for disinfecting morbid materials in practice. Besides these properties there were others, such as harmlessness to the higher animals, freedom from destroying action on tissues and colours, and capability of mixture with different kinds of water. Just as the potable value of water could not be determined by a single test, even though that should be a bacteriological one, so a satisfactory evaluation of a disinfectant could not be arrived at by a germicidal estimation only.

Mr. S. R. Trotman thought the points brought forward by Mr. Lloyd were of much importance. The chief difficulty that arose in deciding upon a standard method was that disinfectants had varying properties and were used under very varying conditions, the latter being in general quite different from those under which they were tested. It was obviously impossible to devise a method which would meet all possible objections, but in drawing up such a process he thought it should be remembered that a bacteriological test on specific organisms favoured some preparations more than others, and that, if possible, some compromise should be made between chemical and bacteriological methods. The author had referred to the age of the solution tested as a disturbing factor in the Rideal-Walker method. That was an important point, for one rarely had to deal with a true solution in the case of a disinfectant. In view of the discrepancies shown by the author, it would at present be difficult to deal with fraudulent preparations, but as soon as a workable process was agreed upon he saw no reason why the sale of disinfectants should not be controlled by the Food and Drugs Act.

Mr. J. Golding said he was not particularly enamoured of standard methods, and in this case, where the science was so very young indeed, it would be a great pity that progress should be hampered by standard methods. If any particular method of testing were made a standard method, he would like it to be laid down as essential that distilled water should be made only in glass condensers.

Mr. L. Archbutt remarked that the directions given for the neutralisation of broth always seemed to him to be a weak point in bacteriological methods. Very varied instructions were given. Some used litmus, others phenolphthalein; some again used sodium carbonate, others caustic soda. Others directed that after neutralisation a certain definite excess of caustic soda should be added. As the amount of free carbon dioxide in the broth must vary, the excess of alkali must also vary if phenolphthalein or litmus were used as indicator, and this, he always understood, had a great influence on the development of some of the organisms.

Dr. F. H. Jacob said that from the practical point of view disinfectants were used, not in distilled water or broths, but in tissues which exercised an immense influence on the action of the germicide. The statistics of any antiseptic should show, under what circumstances the tests were made. It was very necessary at all times that the organisms should grow vigorously.

Mr. Ainslie-Walker said he fully agreed with many of the views expressed by the author. That the public were entitled to the same measure of protection which the law provided against adulterated food stuffs always appeared to him obvious. The exact nature of the control, however, was still a debatable point. Personally, he was strongly in favour of a bacteriological control. Long experience had convinced him that the best method of determining the efficiency of a given disinfectant was to place it in competition with a standard disinfectant of known strength, such as pure phenol, and to make direct appeal to the relative germicidal action on vigorous cultures of micro-organisms, as he had stated in a note to "The Practitioner."* He was aware that the subject did not lend itself to that exact treatment which was given to chemical analysis, but much could be done with the aid of a little system to prevent glaring discrepancies being made, to the discredit of the investigator, and the confusion of the general

*Vol. lxix., No. 413, p. 820.

public. As Mr. Worrall had stated that in his opinion the Rideal-Walker method was unreliable, basing his opinion on certain discordant results recently published, he would like to refer them to a paper dealing fully with these results, which he had written in conjunction with Dr. Sommerville of King's College ("Public Health," March 1, 1906); where any method of test was under examination, the least they were entitled to expect was that the investigators should work with samples of uniform composition. Yet this simple precaution had not been taken in the cases referred to by Mr. Worrall. To show to what extent this question might affect the work of different investigators, he had recently examined a sample of a certain well-known disinfectant which had been standing in his laboratory for some time. The top layer (about 1 in. in depth) was pipetted off and carefully tested. A portion from the bottom of the bottle was then drawn off for comparison. The carbolic acid coefficient of the bottom layer was 20·5, and of the top layer under 0·05 when measured against *B. typhosus*. Exception had been taken to the carbolic coefficient on the ground that the conditions laid down by the authors of the test did not conform to those existing in practise. A complete answer to this would be found in the paper referred to in "Public Health." He would only add that, far from this being the case, by the simple expedient of adopting certain standard diluents, the method was capable of elucidating problems of the greatest practical interest. He had pleasure in supporting the various recommendations put forward by Mr. Lloyd with the object of ensuring uniformity of result. It was to be hoped, therefore, that in formulating the final details of the method upon which they were still engaged, the Committee appointed by the Royal Sanitary Institute would weigh carefully the various recommendations that had been put forward.

Mr. Lloyd, in replying, said that chemical considerations certainly should have some weight in the choice of a disinfectant, and these were briefly outlined in the paper just read. Perhaps they should have been more fully dealt with, but as the title of the paper indicated, bacteriological methods were being specially dealt with. Perhaps the best way to determine the usefulness of a disinfectant, even from the chemical stand-point, would be to modify the Rideal-Walker method in the manner suggested by Mr. Walker and himself, *viz.*, by the addition of known amounts of egg albumin, mucin, or urine when any effect which organic matter may have on the preparation under examination would be revealed by the lowering of the carbolic acid co-efficient. He was now engaged on work in this direction. The lack of uniformity in various samples, no doubt, was a cause in addition to those mentioned, which accounted for some of the varied co-efficients obtained on the same disinfectant and the necessity for thoroughly shaking the sample before any of it was removed for examination could not be too much insisted upon. The figures given by Mr. Walker as to the germicidal values of two layers in one bottle of a well-known preparation were quite in accord with what he himself had obtained. This also applied to some other preparations on the market. Mr. Worrall's point with regard to the selective action of disinfectants on various organisms was very interesting. It was an undoubted fact that various organisms showed differing resistances to one and the same germicide. The *B. typhosus* was selected as the standard organism as it appeared to be generally the most resistant of the non-sporogenous pathogenic organisms with the exception of the *Micrococcus pyogenes aureus*, and he would suggest that for surgical work the effect of a disinfectant upon this organism be specially tested in addition to that on the standard organism. The question of the permanence of disinfecting action in the case of clothes where there was a possibility of return to an infected house was one for the Medical Officers of Health to decide, as it was hardly conceivable that the disinfection of clothing would be carried out without complete disinfection of the house in which the infection had occurred. The toxic action of the preparation should also be specially determined and was quite apart from the general principle of standardisation. The chemist, in the examination of a preparation, could hardly be expected to undertake this test, neither could the action of the germicide on tissues be decided in an ordinary chemical laboratory. He was quite in agreement with Mr. Gelding with regard to the distillation of water in glass vessels, as there was some risk where copper was used that minute amounts of it might be dissolved out, and these would have a very decided antiseptic action. The broth used throughout the experiments detailed in the paper had been found to give very good results, and was published in the hope that it might be adopted for this class of work, because as pointed out by Mr. Archbutt so many different formulæ had been given from time to time, the reactions of which were very varied. At the same time he was prepared to accept any other formula that might be put forward which gave results which were as good.

Mr. C. T. Kingzett wrote that "he thought that of bacteriological tests, results were likely to be in many cases extremely misleading, and never wholly to be depended upon. On the other hand, he was convinced that chemical considerations and the experience gained in the employment of such preparations lead to much more practical results."

Scottish Section.

Presentation to Dr. Thomas Gray, Hon. Secretary, Scottish Section.

On Wednesday, July 26th, 1905, at the North British Station Hotel, Glasgow, shortly after the arrival of the members on tour from the Trossachs, Mr. David Perry Chairman of the Scottish Section, presented to Dr. Gray, the Secretary, a solid silver tea service and tray on behalf of a number of the members of the Section. This was given on the occasion of his approaching marriage, and as a recognition of the valuable services rendered by him during nine years as Hon. Secretary to the Scottish Section. Mr. A. McDonald, Mr. Tatlock and Dr. Clark, all spoke from personal experience of Dr. Gray's work for the Society. Dr. Wiley, of Washington, also spoke, and mentioned that he thought public work was more quickly recognised and rewarded on this side than in the United States. Dr. Gray acknowledged the presentation.

Meeting held at Glasgow, on Tuesday, March 27th, 1906.

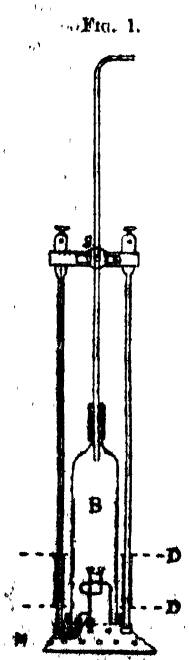
Mr. David Perry in the Chair.

AN IMPROVED FORM OF THE WM. THOMSON CALORIMETER.*

By Thomas Gray, D.Sc., Ph.D.

While it is generally admitted that combustion in compressed oxygen in some form of bomb calorimeter is the only accurate method of determining the calorific value of a solid fuel, the high cost of the apparatus has prevented its general adoption. The demand for a cheaper instrument has led to the invention of a number of calorimeters in which combustion takes place in a current of moist oxygen at a pressure slightly in excess of that of the atmosphere. Some years ago the author, in conjunction with Dr. J. G. Robertson (this J., 1904, 704), carried out a large number of experiments with a calorimeter of this type, designed by Wm. Thomson (this J., 1886, 584). Twelve samples of coal, containing from 60 to 85 per cent. of carbon, were examined and the mean results were found to differ to the extent of −0·7 to −2·9 per cent. from those obtained by the use of a bomb calorimeter. The water value used in calculating these results was determined by weighing the

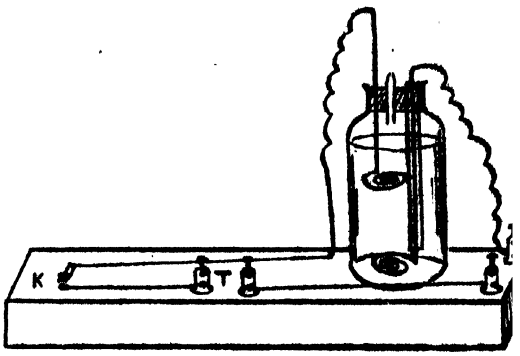
* Made by Messrs. Thomson, Skinner and Hamilton, Sandyford Street, Glasgow.



several parts of the instrument and multiplying the weights by the specific heats of the respective materials.

Differences of 100 to 150 calories were frequently observed between the results of the experiments with individual coal samples. These variations, which in an average coal having a calorific value of about 7000 calories represent approximately 1·5 to 2 per cent. of the total heating power, are largely due to the varying rate of the oxygen current, and to the impossibility of regulating the current so as to ensure perfect combustion of the coal and thorough cooling of the products of combustion which pass through the water in the calorimeter. By making use of the water equivalent determined by the combustion of a sample of coal of known calorific value, the errors due to incomplete combustion and imperfect cooling are partially compensated; the mean results calculated with the value thus obtained were only 0·04 to 1·1 per cent. lower than those determined by the bomb calorimeter (*loc. cit.* 707). These results led the author to conclude that the method might be of service to many users of coal, to whom the cost of a bomb calorimeter would be prohibitive, as a means of controlling the quality of their coal supplies; though the considerable variations referred to above would prevent it from being regarded as a standard method.

In the course of subsequent work with the apparatus some modifications have been introduced with the object of rendering it more durable and more convenient to handle. These consist of (*a*) the replacement of the bulged glass combustion chamber by a straight, somewhat wider, glass tube, (*b*) the substitution of thin perforated brass discs for the original wire gauze baffles, and, (*c*) the addition of arrangements for electrical ignition of the coal. The straight tube has a much longer life than the original form and can be replaced at a much smaller cost. The perforated discs are very much more durable than those constructed of wire gauze, and the possibility of starting the combustion by means of an electric current adds greatly to the convenience of manipulation. The glass calorimeter beaker is made of somewhat thicker glass, but this, as well as the tinned-iron casing, which serves as a heat insulator, retains the original form.



The internal combustion chamber is shown in the accompanying sketch (Fig. 1). The glass tube, B, which is about 6½ ins. long by 2 ins. diameter, sits loosely-clamped on the perforated metal base, M; a brass tube for supplying the oxygen passes through a thick-walled rubber tube fitted to the drawn-out upper end of the combustion chamber, and may be fixed in position by tightening the thumbscrew, S. Two upright brass tubes, joined above by a vulcanite cross piece and provided with terminals, transmit the current for igniting the coal. These tubes are in metallic connection with the metal base and through one of them an insulated wire passes from the terminal to a short insulated vertical rod inside the combustion chamber; a second rod, bent in the form of a ring to support the crucible in which the coal is burned, is in metallic connection with the metal base. The upper ends of these two rods are on a level slightly higher than that of the top of the crucible, and are connected by means of a thin platinum wire which can be made to glow by the passage of an electric current. The perforated metal discs, D, which serve to break up the bubbles of gas passing through the water in the calorimeter, are made to slide on the uprights so as to give access to the crucible.

Fig. 1.

The current may be obtained from storage cells, or from the ordinary lighting circuit when this is available. In the latter case, the resistance shown in Fig. 2 will be of service. To construct this, a wide-mouthed glass bottle, 6 ins. to 8 ins. high and 3 ins. to 4 ins. diameter, is filled with caustic soda solution of approximately 0·1 per cent. strength, and fitted with a rubber stopper. Two electrodes are made by twisting stout copper wire into the form of

Fig. 2.

flat spirals of about 2 ins. diameter, and bending the straight ends of the wire at right angles to these. One of these spirals rests on the bottom of the bottle, the straight portion passing through a glass tube which is fixed in the stopper: the upright wire of the other electrode also passes through the stopper, and a third perforation, into which a glass tube drawn out to a capillary is fitted, permits the gas liberated by the current to escape. The bottle is conveniently fixed to a wooden base provided with terminals, and a circuit-making key, as illustrated. The terminals, T, are connected to those of the calorimeter, and the other two terminals to the electric mains. The distance between the two electrodes is regulated by pushing the upper electrode down till the thin platinum wire glows on depressing the key, K. Further adjustment may be effected if necessary by altering the concentration of the caustic soda solution.

For the determination of the calorific value about 1 grm. of the coarsely powdered coal is weighed out approximately, compressed into a pellet, and weighed accurately. A piece of thin cotton yarn, about 6 ins. long, is tied round the pellet, the short end is cut off, and the pellet in transferred to the platinum crucible along with any powdered coal which may have been detached in the operation; the crucible is placed on the support, the free end of the yarn is tied round the thin platinum wire, and the loose end of the cotton is cut away. The glass combustion chamber, with the brass tube in position shown in the illustration, is placed on the stand and fixed by tightening the thumbscrew, S; a slow current of moist oxygen is passed through the apparatus, which is then immersed in the calorimeter beaker containing 2 litres of water, the temperature of which is 1·5° to 1·75° C. below that of the room. After an interval of 10 minutes the temperature of the water is read to 1/100° C., the oxygen supply is increased so that a rapid current of gas passes, and the cotton fuse is ignited by depressing the key. When the volatile matter is burnt the brass tube is gradually lowered till, at the end of the combustion, the opening is directly over the glowing coke. When the combustion is complete, the rubber tube connecting the oxygen supply with the calorimeter is detached to allow the water to enter the glass combustion chamber, the water is thoroughly stirred, using the apparatus held by the vulcanite cross-piece as a stirrer, connection is again made with the oxygen supply to continue the mixing, and the maximum temperature is observed.

Water value.—This should in every case be determined from the results of a number of combustions of an average coal of known calorific value. If W grms. coal of calorific value, C, are used and the observed rise of temperature is

t, then the water value, V, may be calculated from the equation:—$V = \frac{WC + F - 2000}{t}$ in which F represents the heat developed by the combustion of the cotton fuse.

Fuse correction.—This is determined by burning a measured length of the yarn rolled up into a ball, and noting the rise of temperature. The heat evolved by the passage of the current for the short space of time necessary to ignite the cotton is negligible in this method. It is advisable to arrange to make the current by depressing a key, rather than by means of an ordinary switch, as the experiment may be spoiled in the latter case through inadvertently leaving the switch on during the whole period of the combustion.

A carefully standardised thermometer graduated in 1/10° C. and read to 1/100° C. with the help of a lens will give a degree of accuracy which does sufficient justice to the method.

In modifying the original apparatus, the limitations of the method have been kept in view and refinements, such as the addition of a double jacket for more perfect insulation, which would add considerably to the cost of construction, have not been introduced. A high degree of accuracy is not attainable by this method, and in cases where this is desired some form of bomb calorimeter should be employed.

Yorkshire Section.

Meeting held at Bradford, Monday, March 19th, 1906.

MR. THORP WHITAKER IN THE CHAIR.

THE AVOIDANCE OF NOXIOUS EFFLUENTS IN THE MANUFACTURE OF SULPHATE OF AMMONIA.

BY J. GROSSMANN, PH.D., F.I.C. (OF MANCHESTER).

Since the passing of the Alkali Act of 1863, which has conferred incalculable benefits on the community without in any way interfering with the development of the industry which it primarily affected, a further condition has been added to those which up to that time determined the value of a process, and, however successful a method of manufacturing may be from the purely chemical or engineering point of view, it cannot now be considered satisfactory if it does not comply with the rules dictated by sanitary considerations. Progress in this direction has been naturally slow, as those in authority have liberally interpreted the provisions of the Alkali Act and subsequent enactments of a similar character, in such a manner as not injuriously to interfere with the existing modes of manufacture. In the case of sulphate of ammonia other circumstances had to be considered. Up to within comparatively recent times the bulk of ammonia was produced in gas works, which mostly belonged to municipal corporations. The ammonia liquors produced were either worked up by the corporation itself or by local manufacturers, and the residual products turned into the sewers. In the early stages of sewage purification these residual liquors were not considered to interfere with the subsequent treatment of the sewage so long as the solids were previously separated, and practically all that was required from the sulphate of ammonia maker was to settle the effluents well and to only discharge clear liquor. Even then serious nuisance occasionally occurred, but being strictly local and of rare occurrence, there was no inducement to take exceptional measures against it. It has, however, become an open question whether the ingredients present in the waste liquors from ammonia stills, even when diluted with sewage, may not interfere with the purification of the latter, particularly in the case of biological treatment, and besides the [illegible] situated in towns should be allowed to discharge their effluents into the sewers.

Far more serious is the effect of these effluents when the works which produce them are situated in the country, but even then, as long as the ammonia is only incidental to the manufacture of illuminating gas, the quantity in rural districts will be proportionate to the population, comparatively small, and capable of sufficient dilution. But where it is recovered from other manufacturing processes, such as coking, the quantity becomes disproportionate to the population, and a small village of a few hundred inhabitants may produce as much refuse gas liquor as a town of 100,000 or 200,000 inhabitants. That liquor will be discharged into the nearest stream in its natural concentrated condition, and according to the volume of water available in the stream cause more or less serious contamination.

It is evident that the solution of this problem may be approached from two directions: firstly, by attempting to render the waste liquors innocuous; secondly, by altering the process of manufacture in such a manner as to avoid the formation of the noxious effluent altogether. I have chosen the latter course for reasons which would lead too far to discuss in detail; the principal one, however, being that even if it were possible to remove the cyanogen compounds economically, there would still be sufficient tarry compounds and compounds of the nature of phenols left to render the final effluent noxious, and I know of no method of removing these organic compounds.

In designing my process which involves no startling new discoveries, but is in its main points a new combination of old and well-known reactions, I realised that in order to be acceptable to manufacturers it should as little as possible interfere with the present arrangements. My process, therefore, follows in its main line the present mode of manufacture, and branches off at a convenient point.

In the first place the ammonia liquor is distilled by means of steam in the same stills as used at present, but with this difference, that no lime or other alkaline substance is added.* The resulting liquor contains all the fixed salts of ammonia, besides tar oils and phenols, and salts of sodium. We will, in the first instance, assume that we carbonise 200 tons of coal per day, and that the total quantity of liquor leaving the still is 10,000 galls. per day. We also assume that we work with a fairly dry coal, which from its water in the state of moisture, and from the water formed during carbonisation from its hydrogen and oxygen compounds, yields 10 galls. of water per ton of coal = 2000 galls. of water per 24 hours. Taking it that we have used a quantity of steam equal to 1000 galls. of water for distillation, we find that out of the total quantity of 10,000 galls., 3000 galls. of water is freshly formed in every 24 hours. It is evident that the remaining 7000 galls. can, after cooling, be used again in the scrubbers for absorbing a further quantity of ammonia and ammonia compounds, and that we shall only have to dispose of the 3000 galls. in such manner as to avoid a nuisance.

The figures given here are actual results obtained frequently in gas works and sometimes in coke works. In the latter, however, the quantity of water formed every day often exceeds the figures given here, as the coal used may contain 10 per cent. and more moisture. It can easily be shown from thermodynamical consideration that it is against the interest of the coke manufacturer to use coal with an excessive amount of mechanical water admixture; and if, as is frequently the case, the amount of water freshly formed and added to the products of distillation reaches 20 galls. per ton of coal, and even exceeds it, it would be to the coke manufacturer's advantage to reduce that quantity to its lowest point by using the coal as dry as is practicable.

*My friend, Mr. Watson Smith, calls my attention to the publication of ammonium carbonate which takes place when lime or alkalies are not used, tending to produce complexities in the well-known equilibrium [illegible]. I was quite aware of [illegible] and [illegible] with ammonia-vapour, and have [illegible] that this action is the [illegible] desired [illegible].

[illegal] [illegal] [illegal] [

that it should in no case exceed in cost of working that of the present method. There is a saving in not using lime, which amounts to 3s. per ton of ammonium sulphate, a saving in the quantity of steam used, and the amount of labour should be the same as before. There should be a gain in the yield of ammonium sulphate equal to about 4s. per ton, as no ammonia left in the waste liquors from the stills is eliminated from the system. There is a gain through the recovery of thiocyanate and ferrocyanide, which, taking them at only 1d. per lb., would amount to from 4s. to 20s. and more per ton of ammonium sulphate; and the extra profit on ammonium chloride may be put down at from 9s. to 13s. and more. Against this probable saving of from 20s. to 40s., we have to allow for the cost of evaporation, the cooling of the liquors, and the amortisation and depreciation of the extra plant required. The cost of the first item will greatly depend upon local circumstances. Where the amount of water in coal is normal, there should be sufficient waste heat in coke-oven works to render this operation free from being a charge on the process. In gas works, where there is no waste heat, the charge should not amount to more than 5s. per ton of sulphate of ammonia, as there is always sufficient breeze in these works to spare, which has only a low commercial value, and in some cases almost none. And even where the amount of liquors produced is excessive, it will, in many cases, be found that there will be sufficient waste coal and coke of unmarketable quality which can be used for evaporating purposes. The cooling of the liquor also depends on local circumstances, but even under the most unfavourable conditions the charge for it would be small. The depreciation of plant could only take place in the evaporating apparatus, which is not expensive; and as the total installation is not costly, that item should not seriously affect the process. It must be borne in mind that this process has not been designed with a view to effecting a saving in manufacture, but with a view to alter the old process in such manner that it will comply with such sanitary conditions as may reasonably be imposed upon the manufacturer. If it will accomplish this without extra charge to the manufacturer, it will have done all that can be reasonably expected from such a process.

Discussion.

Mr. W. McD. Mackey said he thought there was only a restricted market for cyanides and ammonium chloride. Ammonium sulphate had a very stable price, and the market was one that was capable of almost indefinite expansion. What were the methods of evaporation to be used?

Dr. Wilson drew attention to the importance of the subject, on account of the large development in the coke oven industry within the last few years. This had caused an increase in the pollution of streams and the atmosphere. By the public health law, it was forbidden to discharge liquors from washing gases into streams and he was therefore glad of the conclusion that this could be totally avoided. In the West Riding of Yorkshire and in all colliery districts the industry was likely to increase. There had been very marked pollution in most of the cases of new works, and if manufacturers could change this it would be for the public good.

Mr. Purdy, speaking as manager of a coking plant, said the difficulty had been overcome at his works. The liquors were passed backwards and forwards through about 200 yards of open launder drain with wood hurdles for taking out the lime, &c., then mixed with the drainage water from the engines and boilers and run into a pond. They were pumped back as required into a tank, and thence to the boilers and so used again. This had done away with the use of boiler composition, as the liquors were found to be boiler cleansers. A careful watch had been kept on the boilers, plates, taps, &c., but no corrosion had yet been noticed.

Mr. Wilfred Wyld asked what materials Dr. Grossmann would recommend for the evaporators. Thiocyanates, sulphides and ammonium chloride would act on all ordinary metals such as iron, &c. Ammonium chloride crystals as obtained from gas liquors were usually in the crude state and almost black, and only a limited amount could be put on the market.

Mr. T. Fairley corroborated Mr. Wyld's remarks, and said he had found ammonium nitrate to be very corrosive, and to act almost like an acid with some metals. He thought the disuse of lime and recovery of ammonium chloride a distinct gain. If ammonium chloride was used for production of manures, the percentage of ammonia would give a limit below which its value could not fall.

Mr. F. Scudder said he was very much surprised at Mr. Purdy's statement that the waste ammoniacal liquors could, after dilution, be used again in the boilers. This was quite opposite to the inference to be drawn from the chemical analysis of such liquors. Coals carbonised in coke ovens seldom yielded less than 12 per cent. of water. The quantity of liquor to deal with would, therefore, on the average, be higher than that assumed in the paper. Colliery proprietors had been forced to face this question of dealing with the spent liquor on account of threatened legal proceedings. The initial cost of a coke oven bye-product recovery plant necessitated, in order that profitable results should be obtained, an increase in the yield of coke over that yielded from ordinary coking ovens, and the recovery of the ammonia in a marketable form. At present, the bulk of the waste liquors produced in the country go, after settlement, directly into the sewers, and that was one of the means of disposal. In Manchester that had not been found to interfere in any way with the bacteria beds or other methods used in the subsequent purification of the sewage. Dr. Grossmann had not stated the ratio of free to fixed ammonia in the liquors. Lime was not to be over-valued for driving off the fixed ammonia, the amount of sedimentary matters which had to be dealt with from the ammonia stills being a serious matter; caustic soda was therefore to be preferred, and as a matter of fact, several works in the south of England were employing caustic soda with economical results. A certain amount of clean water must be used for removing the last traces of ammonia in the scrubbers, and that would have to go into circulation, and would bring up the cost of evaporation considerably. Cyanogen compounds must not be counted upon as a source of profit, since the supply was very much in excess of the demand. He advocated careful consideration of the amount of water in the coals used, since it was advisable to have the ammonia in the most concentrated form possible.

Dr. Grossmann, in reply, said the cyanide industry in connection with gas works was developing very much, and gas works managers continued to put up plants for the recovery of cyanides. The main source of these compounds would, in the future, be the distillation of coal. He thought sufficient allowance had been made in his paper for any reduction in the market value of cyanides, by taking them at only 1d. per lb. From a chemist's point of view he was unable to understand Mr. Purdy's success in using the waste liquors when diluted in boilers, and felt that, sooner or later, accidents would happen and trouble be caused. Corrosion and discoloration in evaporating ammonium chloride solutions could be prevented, and he thought it likely that a method would soon be devised for even overcoming corrosion in many other cases. The relative value of crystallised ammonium chloride to sulphate did not depend on the ratio of ammonia in the two compounds. Ammonium chloride was from £5 to £10 per ton higher in price than the equivalent in ammonium sulphate. The amount of liquor which was produced every day from coal distillation and rendered evaporation necessary could be boiled down at little cost, as in a gas works a large amount of worthless fuel, and in coke works besides, unmarketable fuel waste heat was available. Mr. Scudder's statement that in Manchester the waste liquors from the gas works had not been found to interfere in any way with the bacteria beds or other methods used in the subsequent treatment of the sewage, was diametrically opposite to the information he (Dr. Grossmann) had on this subject from a most competent quarter.

Meeting held at Leeds, on Monday, April 9th, 1906.

PROF. H. R. PROCTER IN THE CHAIR.

RECENT IMPROVEMENTS IN THE BIOLOGICAL TREATMENT OF SEWAGE.

BY W. J. DIBDIN, F.I.C., F.C.S., ETC.

In February, 1904, I had the honour of placing before the Society certain suggestions with reference to the use of horizontal layers of slates, tiles or other suitable material for the purpose of facilitating the destruction of the matters held in suspension in sewage, and thus "effectually meet the sludge difficulty."

I now propose to submit for the consideration of the members the results of actual work accomplished on the lines then laid down. In the previous paper referred to, a series of results were given showing the effect on the organic matters in solution when the layers of slate were placed at intervals of 2 ins. apart. For the purpose of testing the question as to whether satisfactory results could be obtained when the layers were placed at greater or less intervals, I am permitted to quote from the results given by Dr. David Sommerville of the State Medicine Laboratories, King's College, London, in a paper which was published in "Public Health," September, 1904, *viz.* :—

"The immediate object of the experiments to be described was to determine the degree of purification, as measured by decrease in albuminoid ammonia, corresponding with definite spaces between the slabs of slate, with the view of establishing, if possible, an optimum space.

"Crude sewage, obtained through the kindness of Dr. Clowes from the London outfall, was used throughout. Operations were carried out in two laboratory tanks of different sizes, containing horizontal rows of slate slabs, arranged at distances apart, varying from 1 in. to 12 ins. Care was taken that the conditions of temperature, time given to filling and emptying the tank, time of contact of sewage with slates, &c., were as nearly as may be constant. The temperature was maintained at 16° C. to 18° C. Half an hour was allowed for filling a tank, half an hour for emptying, and two hours for undisturbed contact. Five hours were allowed for rest.

"The optimum vertical space between the rows of slabs, as indicated by the experiments, appears to be about 4 ins. A few examples selected from a large number of results will serve to make this manifest":—

No. of experiment.	Distance between rows of slab.	Percentage reduction of alb. ammonia.

The Corporation of Devizes, having decided to make a series of experiments with the view of ascertaining how far the method of filling the primary contact beds with slate would answer for the sewage of that town, instructed their Surveyor, Mr. F. G. Billingham, to construct a pair of experimental beds, the first to be filled with slate placed at from 2 ins. to 3 ins. apart and having an initial gross capacity of 12½ cb. yds. and the second having a initial gross capacity of 25 cb. yds. and filled with breeze. This arrangement was intended to test the relative working powers as to quantity of sewage treated. If the preliminary experiments held good in practice the reduction in the size of the primary beds would be warranted. The results entirely confirmed the suggestion that this reduction in first cost would be justified.

The beds were first started at work in January, 1904, and were continued at work for 18 months when they were put out of use as the whole of the sewage was then treated on the new beds which had been constructed to replace the old system of chemical precipitation and sludge pressing.

The following are the results of the analyses made from time to time of the sewage, slate bed effluents and breeze bed effluents:—

These results were so far satisfactory in that they showed that the work of treating unscreened and unsettled sewage on the slates could be accomplished without nuisance from accumulated sludge and with the production of an effluent which was ready for final treatment on suitable fine beds. The effluents from the breeze beds, however, were not up to the standard and a careful examination was made as to the cause, when it was found that a large proportion of the material was too coarse, much of it running to 1—2 ins. in diameter. The bed was then refilled with suitable fine material, averaging from a quarter of an inch to one thirty-second of an inch. This was satisfactory.

[The analytical results obtained are given in Table (Second Series) on next page.]

It was noticed that at the end of the discharge from the slate beds a small quantity of semi-black matter flowed out from the bed. This was retained on the surface of the fine bed and there underwent disintegration and on being removed and thrown out on the surface of the adjoining ground dried up into a condition resembling ordinary mould, no offensive odours being emitted in the process. This was so far satisfactory in that it meant that there was a self-cleansing action going on by which the capacity of the beds would be retained for a longer period than would otherwise be the case. A sample of this matter was collected and submitted to careful chemical and bacteriological examination with the following results, *viz.* :—

	Per cent.
Water	38·6
Organic matter	25·2
Mineral matter	36·2
	100·0

The organic matter was found to consist almost entirely of the zoogloea masses of bacteria, the appearance under the microscope being comparable to an ordinary gelatin culture. A sample of the deposit on the top of the slate at about 18 in. below the surface of the beds was then collected, as also one from the under surface of the slates in the same position. The following are the results of the examination :—

Sept. 15, 1904.	Deposit from top of slate 18 ins. below surface.	Deposit from under side of slate 18 in. below surface of bed.
	Per cent.	Per cent.
Moisture	75·3	65·7
Organic matter	9·5	12·7
Mineral matter	15·2	21·6
	100·0	100·0
	Per cent.	Per cent.
Organic matter in the dry material	38·4	37·2
Nitrogen in the dry material	1·94	5·1
Bacteria per grain of wet material	=199,000,000	207,000,000

The microscopical examination of the matter from the upper surface of the slate revealed the presence of mineral *débris*, grit, &c. Spiral vessels, human hairs, leptothrix, anguillæ, vorticellæ, various starch cells, &c.

The matter from the under surface of the slate contained diatomaceæ, infusoria, starch cells, spiral vessels, monadina, spores of fungi, confervæ, hairs, muscular fibre, fragments of insects, &c.

On March 10th, 1905, further samples of the black "humus" discharged from the slate bed were collected and examined when fresh and after weathering, with the following results :—

	Fresh material.	Weathered mat
Appearance.	Black and smooth spreading.	Like ordina mould.
Odour.	Sewage.	None.
	Per cent.	Per cent.
Organic matter in dry material	40·5	32·5
Mineral matter in dry material	59·5	67·5
	100·0	100·0
Nitrogen per cent. on organic matter	8·42	7·62

The high nitrogen in the black "humus" from slate bed was doubtless due to the large number of li organisms it contained. The experiment on "weathering" is of the highest importance as sho the manner in which the solid matters of the sewage be disposed of without nuisance, especially when remembered that these beds receive the sewage wit being either screened or settled.

After the beds had been at work for 14 months, b charged on an average twice a day, the capacity of slate bed was measured, when it was found to hold 50 cent. of the original gross cubic content of the tank to the level of the slate filling. It was then rou flushed out when the capacity rose to 64 per cent. S of the slates at the sides were then removed, in orde allow the remainder of the slates to be flushed wi hose which so thoroughly cleansed the slates that water capacity rose to 82 per cent., which was the c content of the bed when newly filled with the sl thus showing that by this simple method the beds be restored, when required, to the condition of a bed. This particular bed, being the first constru on a working scale was not laid with the same skill now obtainable, nor were the slates as well split, espec the supporting blocks between the different layer slate. As now arranged the water capacity of a bed is about 87 per cent. of the total cubic conten the tank up to the level of the top layer of slate.

The whole of the sewage of the town was turned o the new installation on Sept. 12th, 1905, with the re of entirely confirming the above experiences with experimental beds.

[The analytical results obtained will be seen in T (Third Series) on next page.]

The effluent from the fine bed is then discharged o land.

The deposit from the slate beds has been allowed to on to the surface of the fine beds and there collecte channels, from whence it is removed and thrown u heaps on the surface of the fine beds to undergo weathe after which it is again spread out on the surface of the In future installations arrangements will be made this matter being discharged on to a special area of a or similar material, so as to keep the surface of the beds as open as possible.

Experimental trials of the use of the slate have been made by the Corporation of Trowbridge, v however, placed the effluent from a septic tank u them as well as on beds filled with granite, sandst coke and other material. The analyses of the respec effluents were made by Mr. Waterfall, F.I.C., &c., Bristol, who reported that "in either case slate gave best results," and as a result the Corporation are fil one half of the primary beds with that material.

Slate beds are also in operation at the works at E Wycombe for the purpose of eliminating the slu difficulty, the effluent from these being discharged di on to the land with satisfactory results.

From these various results it is evident that the gestion to use beds filled with layers of slate divided distance pieces has been justified, and that the meth although doubtless subject to improvement, deals ef tually with the sludge difficulty, and renders the sew fit for the further process of purification on either con

beds, sprinkling beds or on land when such is obtainable of suitable quality and quantity.

With regard to the discharge of sewage direct into the sea it is evident that the preliminary breaking up of the solid matters by inoffensive digestion on a slate bed would be an immense improvement over the common custom of sending it in with all the solid matters which float along the coast and form offensive deposits on the shore, as I found to be the case in one instance where the whole of the foreshore for a considerable distance at low water was reeking with sulphuretted hydrogen, and the stones and rocks and many of the seaweeds coated with *Beggiatoa alba*, the well known "sewage fungus," whilst *Bacillus coli communis* was abundant in all the samples collected. Such a state of things could not arise if the sewage before its discharge had been subjected to preliminary aerobic action on such beds as described above.

Discussion.

Dr. H. M. Wilson asked if, in the figures of purification given, percentages were calculated on the crude sewage, or on the sewage without its suspended matters. He also inquired what amount of suspended solids was left in the effluent, and what amount remained on the slate bed to be washed out. What was the nature of the suspended solids and the percentage of organic matter in them, and was there any method of distinguishing between living organic matter which would help purification, and dead organic matter which tended towards putrefaction? The advisability of adopting the proposed method was a question of cost. In this neighbourhood it might not be a cheap method, but the extra capacity of the beds was undoubtedly an advantage. Dr. Wilson pointed out that, although in testing one apparatus against another, percentage purification was a good criterion, the fitness of an effluent for a stream could not be thus ascertained, as the same percentage purification gave very different effluents with a strong sewage and with a weak sewage. Analyses were useless unless made on the matters in solution in sewage, after allowing suspended solids to settle. Some account, however, must also be taken of these solids, which usually contained about half the albuminoid nitrogen.

Mr. F. W. Richardson protested against the custom of reporting on sewages in the crude state without first allowing suspended solids to settle. This gave erroneous ideas as to efficiency of purification. The method of shaking up the whole, and endeavouring to get representative samples was unscientific, and consistent results could not be obtained in determinations of albuminoid ammonia, &c.

Mere settlement gave a large purification on account of the removal of flocculent matter, and this result was commonly credited as due to the special method of treatment employed by sewage-works engineers. He was pleased to hear that the septic tank was not a necessity, as its disuse did away with offensive odours. It was also satisfactory to know that the aerobic process was better, and that an approach could be made to natural methods, in which organic nitrogen was converted to inorganic nitrates, as in the case of waters in filtering into wells over wide areas.

A Member asked if slate tanks would work with brewery effluents.

Mr. Davies asked if Mr. Dibdin had ever tried the direct comparison of a primary slate bed followed by a sprinkling filter with the combination of two slate beds. He thought it would be of interest if Mr. Dibdin could give a few remarks concerning the actual chemical changes which occurred in the aerobic and anaerobic treatment.

Mr. Armytage said that at Yeovil the sewage from the fellmongering and leather-dressing yards of the glove factories was difficult to treat. Experiments had been tried for four years before finally adopting the septic tank system. Mr. Dibdin's suggestions, *re* fine beds, had been carried out there. Double contact was adopted with final deposition on land to satisfy the Local Government Board, thus making triple contact. Although the experimental plant was laid down within three yards of a public footpath, cottages and a glove manufactory, no complaints had been made as to nuisance or smell during the time the experimental plant was in use.

Mr. Fairley asked if Mr. Dibdin had thought of improving the fine beds on the lines of the other beds, since the durability of the latter had been so much increased? As contact beds depended on surface efficiency, thin laminæ of slate giving more surface than coke, would improve their value. One great advantage was that the increase of surface also gave increased capacity. The difference between septic tanks and slate contact beds was, that the former depended on anaerobic or putrefactive fermentation for success, whilst the latter worked through aerobic decomposition and oxidation. If sulphur were present in the first instance sulphurotted hydrogen and other offensive gases would be evolved. He asked if the laminated sandstone found in this neighbourhood could take the place of slate.

Mr. Harrison said that numerical values were comparatively worthless for gauging the purification of sewage, for the quality of the organic content must be taken into account in preference to the quantity. Mr. Dibdin had not mentioned what became of the matter washed out from the filters, and the cost of cleaning the slate bed and dealing with the undigested solids had not been given. The effluent from a slate filter did contain some suspended matter, and if this were placed on a contact bed, clogging and reduction in capacity would result. This would necessitate either remaking the bed or washing the bed material, and would consequently greatly increase the cost of treatment in a place like Leeds, where material was only obtained at a good price. He agreed that the ideal treatment should be aerobic. The difficulty in sewage works was not in purifying the matters in solution, but the suspended matter. The capital cost of the slate bed method in Leeds would render its use prohibitive.

Mr. W. McD. Mackey understood that the figures given could be taken as comparative in the same sewage. He was glad to see the diagrams giving the degree of aeration of the effluents. The albuminoid ammonia determination which had been employed so long, although very useful, was sometimes misleading, and he thought the degree of aeration of the effluent gave a very useful factor when considering the success of a sewage purification process. It was known that there were certain processes which took away oxygen. Of two similar effluents therefore, the one containing the more oxygen was the better. Dealing with the general question of the purification of sewage, he considered it was only fair that an engineer should get some credit for bringing about settlement of suspended solid matter.

Mr. Dibdin, in reply, said it was wrong to claim special credit for natural sedimentation in a process, because it was common to all methods. Suspended matter should be treated as such, and separated totally from dissolved matters. The percentage purification was stated in terms of dissolved matters in the sewage, the figures relating to suspended matters being given in the accompanying tables. It was impossible to distinguish between living and dead matters by chemical methods, but an approximate estimate might be obtained by microscopic examination and bacterial cultures. The best method of meeting the albuminoid nitrogen difficulty was by estimating the organic carbon and nitrogen, but this was seldom necessary for practical purposes. He had not tried slate beds for brewery effluents, and would be glad of an opportunity to do so. It was immaterial whether sprinklers, contact beds, or land were used for treating the effluent from the slate beds. The essential object of the slate bed was the retention and aerobic bacterial treatment of the suspended solids, the effluent thence passing to contact beds, sprinkling beds, land or tidal river, &c.

The essential difference between the aerobic and anaerobic treatment was that, in the first case, the action

took place in the presence of air, and consequently by organisms which effected disintegration, without the production of offensive gases, and whose action moreover was more rapid and complete than that of the anaerobic organisms which evolved grossly offensive odours, and to a large extent stultified themselves by their own emanations. He had not proposed slate for secondary beds, as the weight of the closely compacted fine slate would involve too large a cost for railway carriage of the material. For the same reason and also because of the difficulty of splitting it to the required thinness, sandstone was less suitable, although it worked well as an ordinary filling material, but did not give the extra working capacity obtained by flat, thin superposed surfaces such as tiles, slate, &c. He agreed with Mr. Harrison that quality was more important than quantity in sewage constituents. In the paper it had been explained that the matters washed out of the slate beds dried up on exposure to the air to a condition resembling mould without nuisance, instead of forming the usual "sludge lagoons" so commonly met with.

The question of the putrefaction in effluents had been raised. There was no complaint of smell at Yeovil or elsewhere where contact beds were used, but in many other cases serious nuisance was caused by the excessive putrefaction in the tanks, and the gases evolved were the cause of trouble when the liquid was distributed over the beds by the sprinklers. An effluent which maintained its aeration over 50 per cent. of the total possible was a good one and could not putrefy. With regard to the cost of the slate beds, he again pointed out the advantage of such a durable and permanent material. Effluents containing as much as 7 grs. of suspended matter per gallon had been satisfactorily dealt with by the same one acre bed at Barking Creek for 15 years, without indicating future trouble. Similar experience had been gained at many other—in fact innumerable other—places, and it therefore could not be seriously maintained that fine beds would not work. In fact, Manchester alone was extending their use largely. With reference to the cost of the slate, 12s. per cubic yard was equal to coke, &c., at 6s. in consequence of its giving a twofold working capacity. In addition to this, it was permanent and could be cleansed when required; in fact there was no comparison between the two in the long run. He was sorry that Leeds had not tried the slate in the manner in which he proposed it. They had a small sample at high railway rates, and tried it for sprinkler beds and as a substitute for fine beds, but not for the specific purpose for which it was introduced, *viz.*: primary contact beds to ensure the aerobic preliminary treatment of the crude sewage. After all the work that had been done by Mr. Harrison, he was glad to find him in agreement as to the aerobic principle being the correct one. He (Mr. Dibdin) had been fighting this battle for years, and congratulated himself that at last the point was being conceded in all directions. Even the strongest supporters of the anaerobic theory admitted that it was quite possible to "over septicise" the crude sewage, which was a convenient phrase to intimate that putrefaction was a blunder. In due time they would admit that the action took place to the best advantage when the sludge was laid out in thin layers on a well drained surface in the presence of air, as in land treatment under the best conditions. This was precisely the principle and practice of the slate bed, which thus came nearer to nature's method than any artificial treatment which had been proposed.

Journal and Patent Literature.

I.—PLANT, APPARATUS, AND MACHINERY.

(*Continued from page* 363.)

High vacua; Production of —— by means of liquid air. G. Claude and R. J. Lévy. Comptes rend., 1906, **142**, 876—877.

THE principle of the method consists in raising the degree of exhaustion by stages. The space to be exhausted is connected with a series of two or more vessels containing charcoal. The apparatus is first exhausted by an air pump or water pump, which is then shut off, and the first (outermost) vessel of charcoal is immersed in liquid air, thus raising the vacuum in the space to be exhausted and the other charcoal vessels. The first charcoal vessel is then shut off and the second cooled, and this procedure is carried farther if necessary. The operation is very rapid and economical of liquid air; in fifteen minutes, starting from a pressure of 2 mm. of mercury, five Crookes tubes of 1 litre capacity each, were simultaneously exhausted to extinction of discharge.—J. T. D.

ENGLISH PATENTS.

Separating apparatus; Centrifugal ——. F. Kaehl, Berlin. Eng. Pat. 6782, March 30, 1905.

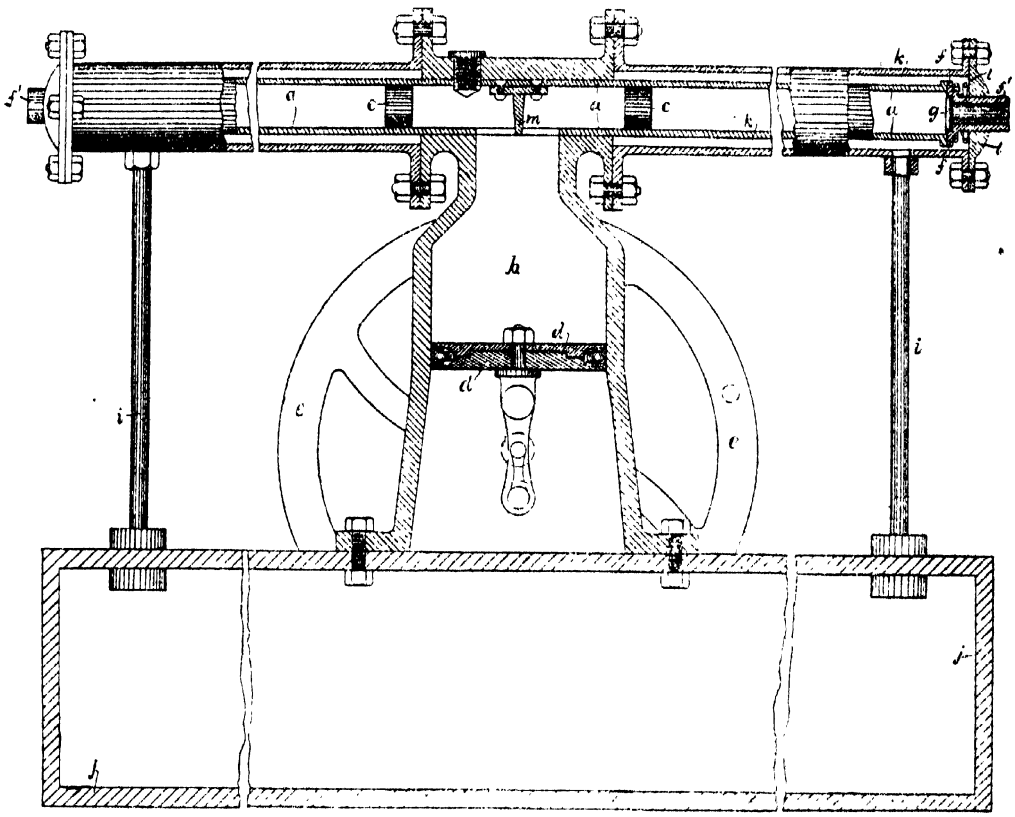
SEE Ger Pat. 155,562 of 1903; this J., 1905, 629.—T.F.B.

Separating apparatus; Centrifugal ——. Aktiebolaget Separator and A. J. Ericsson, Stockholm. Eng. Pat. 19,109, Sept. 21, 1905.

THE improvement is in respect of the method of transporting the solids along the periphery of the bowl of the separator to points above the scrapers which carry the solids towards the centre of the bowl. Scrapers attached to a cross-piece mounted on the shafts of the ordinary scraper wheels are provided; but they are placed above the ordinary scrapers, and move along the periphery of the bowl.—C. S.

Liquids; Apparatus for treating —— with gases or vapours. V. Defays, Brussels. Eng. Pat. 6850, March 31, 1905.

SEE Fr. Pat. 352,719 of 1905; this J., 1905, 959.—T. F. B.



Mixer or agglomerator; Vertical ——. W. B. Westlake, jun., Swansea. Eng. Pat. 8855, April 27, 1905.

A VERTICAL cylinder is divided into an upper and a lower chamber by a horizontal partition. The upper chamber has a vertical, concentric, inner cylinder, and the lower one is divided by horizontal, perforated shelves. A central vertical shaft, on which blocks carrying agitating arms are fixed, passes through both chambers and is driven by spur-wheels fastened to it both above and below the casing. The material to be treated is fed into the top of the upper inner cylinder and passes from the bottom to the annular space, and thence to the shelves of the lower chamber, from the lowest of which it is taken away. An induced draught fan placed at the top, and communicating with the annular space, draws a current of heated air, mixed with a regulated supply of any desired reagent from a measuring apparatus through the lower compartments, and also carries away any vapours given off during the operation. The material in the upper chamber can be subjected to the action of steam or gas, which enters by a pipe passing through the outer casing, into and around the annular space and then into the inner cylinder. Reference is made to Eng. Pats. 853 of 1872, 8731 of 1885, 2807 of 1886, 2231 and 14,852 of 1899, and 21,300 of 1903 (see this J., 1887, 134; 1900, 231), and anything described therein is expressly exempted from claim.—W. H. C.

Purifying, humidifying or cooling air or other gaseous fluids; Impts. relating to ——. T. F. Shillington and J. A. Hanna, Belfast. Eng. Pat. 10,552, May 19, 1905.

THE air or gas is passed through a wheel formed of concentric rings or hoops, and which, on being rotated, serves to dissipate the humidifying liquid as spray amongst this air or gas, and the air or gas thus treated is subsequently passed through a cylindrical chamber provided with baffle-plates to cause the deposition of the liquid. —W. H. C.

Compressing air; Apparatus for ——, *applicable also for pumping liquids.* W. B. Barker and W. MacConnal, Liverpool. Eng. Pat. 10,557, May 20, 1905.

Two horizontal cylinders, *a*, having movable plugs or pistons, *c*, are mounted above a common vertical cylinder, *b*, provided with a piston, *d*, actuated by the wheel, *e*. The cylinder, *b*, is filled with a liquid such as water or oil, and during its upward stroke the piston, *d*, forces the liquid past the midfeather, *m*, into the horizontal cylinders, *a*, *a*, and causes the pistons, *c*, *c*, to move outwards. The pistons, *c*, drive the air in the cylinders, *a*, through the valves, *f*, into the annular jacket, *k*, and thence through the pipes, *i*, provided with non-return valves into the compressed-air reservoir, *j*. At the end of the upstroke, when the pistons, *c*, reach the end of the cylinders, *a*, the valves, *f*, are closed by springs, *l*, and as the piston, *d*, moves downwards, air enters the cylinders, *a*, through the pipes, f^1, and non-return valves, *g*.—W.H.C.

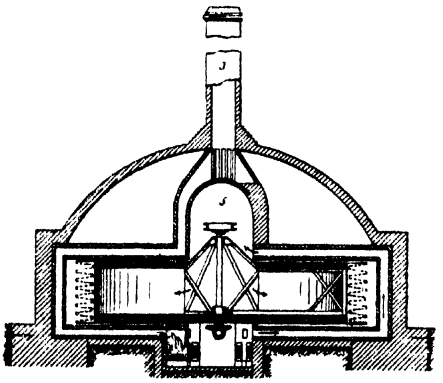
Fluids; Apparatus for effecting interchange of temperature between ——. E. F. Daniel and G. Thornley, Burton-on-Trent. Eng. Pat. 19,724A, Sept. 29, 1905.

THE vessel containing the liquid to be cooled, is fitted with any desired number of devices for ensuring the circulation of the attemperating liquid, each consisting of two concentric tubes with a narrow annular space between them, the cooling liquid being introduced through a third concentric tube, and delivered through a terminal chamber into the annular space, which it traverses as a thin layer. —C. S.

Drying and conditioning machines. J. H. Lorimer, Germantown, Pa., U.S.A. Eng. Pat. 22,816, Nov. 7, 1905.

SEE U.S. Pats. 811,306 and 811,307 of 1906; this J., 1906, 211.—T. F. B.

Hygroscopic packing materials; Impts. in ——. P. W Braun, Feuerbach, Germany. Eng. Pat. 23,658, Nov. 17, 1905.



CALCIUM chloride, phosphorus pentoxide or other hygroscopic substance is finely ground, mixed with plaster of Paris in the proportion of 4 parts to 2, and then incorporated with ground peat (1 part), the whole being exposed to damp air, whereby it is rendered hard and unbreakable by shock whilst in use.—C. S.

UNITED STATES PATENTS.

Drying apparatus. W. Bell, Burgbrohl, Germany. U.S. Pat. 814,666, March 13, 1906.

THE drying chamber of the apparatus is circular in section, and in it a drum is mounted to turn about a vertical axis, means being provided for rotating the drum at suitable varying speeds. The periphery of the drum is perforated, or made of wire fabric, and provided with a number of perforated rings to form a number of grooves to which the

articles to be dried are attached by means of detachable perforated straps; the rings and straps may be of wire fabric. An operating drum is provided to wind on the detachable straps, and apply them to the drum. A number of "ventilating ladles" in the drying drum force hot air through the drum walls. The circular drying chamber has a central dome, 5, and there is a

central space beneath the chamber, and a number of furnaces arranged round the space, to which an air-shaft passes from without. From the furnaces flues pass radially in the floor of the drying chamber, vertically through the wall, and radially in the cover of the drying chamber, and upwards in the wall of the central dome, to the chimney, 3. Air channels on the sides of the flues communicate with the upper part of the central space and with the dome, as also a number of inclined air channels with the lower part of the central space, and with the circular drying chamber on the periphery. —W. C. H.

Kiln; Downdraft ——. G. E. Snowden, New Cumberland, W. Va. U.S. Pat. 816,752, April 3, 1906.

The kiln is provided with: a central cylindrical flue occupying one-third of its floor area; with radial flues extending from this central flue and closed at their outer ends; with independent segmental flues placed at opposite sides of the central flue, a series of radial flues extending from the segmental flues and disposed between each pair of floor-openings therein, chimneys placed in the kiln-walls, each communicating with a radial flue from a segmental flue, and also with heating-furnaces placed in the kiln-walls alternating with the chimneys.—A. G. L.

Furnace; Hot-blast ——. J. M. McClave, Toronto, Ohio. U.S. Pat. 816,877, April 3, 1906.

The claim is for a furnace with a closed ash-pit into which the admission of air can be regulated. The furnace is provided with air-heating flues, formed in the side walls and top, with separate outlets into the front and rear ends of the combustion chamber.—W. H. C.

German Patent.

Vacuum evaporating apparatus. H. André. Ger. Pat. 165,006, Feb. 23, 1904.

In order to render the apparatus claimed in Ger. Pat. 147,777, Jan. 16, 1902 (see Eng. Pat. 6847, March 24, 1903; this J., 1903, 787) suitable for the evaporation of thick liquids, and for roasting, carbonising, &c., the tubes rising from the baffle-plates are connected to a central hollow shaft, which rotates with the baffle-plates, and is provided with outlets for the vapours evolved. The lower end of the hollow shaft is furnished with a discharge-tube for the less volatile products formed. Further, in order to carry forward the material under treatment, the hollow shaft, or the under sides of the baffle-plates, are furnished with inclined plates or blades, of which alternate ones are longer than the others. The material falling from the baffle-plates on to the bottoms of the evaporating pans, is pushed by the longer blades towards the shorter blades, which in turn force it into and through the tubes connecting the different pans, whilst similar blades fixed to the under sides of the pan-covers distribute the material over the baffle-plates.—A. S.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 365.)

Coals. E. Donath. Z. angew. Chem., 1906, **19**, 657—667.

The following is a summary of the author's arguments:—(1) In the majority of types there is a decided distinction between lignites (brown coals) and pit coals. (2) The transformation of lignite into coal cannot be brought about by an extension of the carbonising process over a considerable period or by contact-metamorphosis. (3) There is a marked difference in chemical composition between the substances which have given rise to the formation of lignite and of pit coal. (4) Lignite has its origin in substances containing lignin, whilst the material from which coal is developed appears to consist largely of proteids, which are probably of animal origin. (5) The formation of coal has in the majority of cases and for various reasons been accompanied by a more or less extensive process of distillation under pressure, the products of which are found in coal in a polymeric, condensed or other chemically changed state. (6) The caking property exhibited by certain coals is due to the presence of these pitch-like substances and products resulting from the decomposition of proteids, their amount being closely connected with the relative proportions of nitrogen and sulphur present in coal.—D. B.

Calorimeter; Alcohol —— for coal testing. W. M. Wallace. XXIII., page 445.

English Patents.

Peat and the like; Extracting moisture from —— [electrically]. W. Simm, Prescot, Lancs. Eng. Pat. 4792, March 8, 1905.

The peat is compressed by a plunger and is then subdivided by a number of electrode plates connected alternately in parallel with the poles of a dynamo supplying an alternating current of, preferably, over 200 volts. A dummy plate is used to make holes in the peat for the insertion of the electrodes, and means are provided for closing up the electrodes as the peat shrinks.—C. S.

Briquettes; Manufacture of —— [Utilisation of distillers' refuse]. Baron Armstrong, Rothbury, Northumberland. Eng. Pat. 6784, March 30, 1905.

"Pot ale" or distillers' refuse is concentrated by evaporation to the consistency of a thick syrup, heated and then well mixed with coal. When the briquettes are required to be waterproof, a little resin and linseed oil "foots" or glucose, or dextrin are added. A small quantity of tar improves the quality of the briquettes.—R. L.

Compressing air, or air and gas [for supplying burners]; Apparatus for ——. A. Clama, London. Eng. Pat. 5892, March 20, 1905.

The claim is for a gas-compressing apparatus for supplying gas under pressure to a burner. The compressor is actuated by a hydraulic piston and cylinder, connected to a supply of water under pressure. The admission of water to the hydraulic cylinder, and its subsequent expulsion when it has effected its work, is controlled by a special distributing valve, moved by springs, compressed by an auxiliary piston attached to a rod which passes through the hollow rod of the distributing valve, and is released by a rocking lever which bears against the rod of the distributing valve and the rod of the hydraulic piston. A self-starting device,

consisting of a spring catch, is provided to prevent waste, should the pressure in the water main fall below that necessary to work the apparatus.—W. H. C.

Gas producers; Construction and method of operation of ——. H. Lane, Manchester. Eng. Pat. 10,632, May 22, 1905.

A SUCTION producer is enclosed within two concentric casings, forming two annular spaces; the inner space, through which the hot gases from the producer circulate, is in communication at its upper end with the interior of the producer and at its lower end with the gas-outlet pipe; whilst the outer annular space, down through which the air is drawn on its way to the fuel, serves as the steam-generating chamber, an automatically regulated supply of water being caused to trickle down troughs or channels arranged on the exterior surface of the inner casing. The scrubber, through which the generated gases are drawn, is provided at the top with a flexible diaphragm, the pulsation of which, at each suction by the engine, is caused to operate the valve which controls the water supply to the producer. On starting the producer, the gas outlet pipe is put into communication with a chimney provided with means for increasing its draught, consisting of an annular grate or cup on its exterior, in which light combustible material may be burned, and perforations, through which the gaseous products are directed into the chimney.—H. B.

Gas producers; [Suction] ——. J. Fielding, Gloucester. Eng. Pat. 14,498, July 14, 1905.

To ensure the automatic regulation of the water supply in accordance with the steam requirements of the producer, water is allowed to descend in a continuous stream or series of drops near the air inlet. When the engine is not sucking, the water falls into a waste pipe and passes away, but at each suction stroke, the current of air deflects the descending stream of water into the producer.—H. B.

Grids for gas purifiers; Impts. in ——. F. H. G. Morris, Old Brentford. Eng. Pat. 10,971, May 25, 1901.

IN a gas purifier having distributing conduits arranged for the horizontal flow of gas, the purifying material is supported upon horizontal trays or grids placed one above the other at suitable intervals. The purifier casing is filled up with loose purifying material to the level at which the first grids are to be arranged, the first layer of grids is then put in place; the purifying material is next filled in to the level of the second grids, which are then put in place; and so on, until the casing is full.
—H. B.

Spent oxide from gas purifiers; Treatment of —— for the purpose of revivifying and rendering same fit for re-use. A. F. Browne, London. Eng. Pat. 26,899, Dec. 23, 1905.

SPENT oxide is revivified by passing through it such an excess of air as not only suffices for that purpose, but also to carry off much of the heat generated by the chemical action, and largely remove the deposited naphthalene. If necessary the product may be kept moist by means of steam or water spray.—H. B.

Sulphocyanides [Thiocyanates]; Manufacture of —— [from crude coal gas]. J. Tcherniac. Eng. Pat. 2708, Feb. 3, 1906. VII., page 427.

Mantle for incandescent lighting; Spontaneously-igniting incandescent ——. M. Pick, I. Fischel, G. Imiela, and E. Wallnig, Berlin. Eng. Pat. 19,435, Sept. 26, 1905.

AN igniting pellet composed of platinum black and argillaceous earth is attached to the inside of the mantle at a distance not exceeding 3 cm. from the gas inlet, and is connected with one or more ignition strips composed of ammonium-platinum chloride. (Reference is directed to Eng. Pats. 15,414 and 20,017 of 1898; this J., 1898, 1032, and 1899, 27.)—H. B.

Incandescent gaslight bodies; Improved process [and apparatus] for forming and hardening ——. Export-Gasglühlicht G.m.b.H., Neu-Weissensee, Germany. Eng. Pat. 24,032, Nov. 21, 1905. Under Int. Conv., Dec. 30, 1904.

IN forming and hardening mantles on a machine by this process, each mantle is rotated about its axis slowly and intermittently, instead of continuously and rapidly, the rotatory movements occurring preferably whilst the burner is below and not within the mantle. At each rotatory movement the mantle moves through only a small part of a circle. In the machine described, a number of horizontal discs are caused to rotate continuously by means of suitable driving gear, each disc having on its under side a pin, fixed excentrically. Beneath these discs a corresponding number of rotatable toothed wheels are so arranged that the pins on the rotating discs engage in the hollows between the teeth, whereby the wheels are caused to turn intermittently, a little at a time. The mantles to be treated, are suspended from wires attached to the under side of these wheels, and are thus given the desired gradual and intermittent rotation. A corresponding number of burners is provided below the mantles.
—H. B.

Mantles; A medium for fixing igniting material on incandescent ——. N. Hoock and L. Zucker, Berlin. Eng. Pat. 255, Jan. 4, 1906. Under Int. Conv., Sept. 19, 1905.

IGNITING pellets are affixed to incandescence mantles by means of a mixture of aluminium hydroxide, 35 parts; silicic acid, 5 parts; boric acid, 59 parts; with the addition of a small quantity of magnesia and carbonate of lithium or other alkali metal.—H. B.

Filaments for electric incandescence lamps; Process for the production of incandescence ——. Deutsche Gasglühlicht Akt.-Ges., (Auerges.), Berlin. Eng. Pat. 19,379, Sept. 25, 1905. Under Int. Conv., Jan. 17, 1905.

SEE Fr. Pat. 357,842 of 1905; this J., 1906, 116.—T.F.B.

UNITED STATES PATENTS.

Fuel gas; Process for making and burning ——. W. T. Griffin, Plainfield, N.J. U.S. Pat. 816,314, March 27, 1906.

A MIXTURE of superheated steam and finely-divided carbonaceous material is passed through a heated zone, the gases formed being conducted back through the zone to a point outside the same; a supply of oxygen is introduced into the current of gases and this mixture is burned beneath the heated zone.—R. L.

Gas calorimeter. C. E. Sargent, Chicago, Ill. U.S. Pat. 816,042, March 27, 1906.

THE heater is combined with a fuel meter and with a water supply. A trough which receives water from the heater is divided into two parts, each of which has a separate opening. The trough is pivoted below its centre and is capable of occupying two positions, moving under the influence of the water it contains, at a given period which is controlled by the meter. This control is effected by means of a stop to prevent the movement of the water-deflecting device, and an electromagnet to withdraw the stop. A partition in each trough section can hold back a portion of the water in each section after the trough has moved from one position to the other.
—R. L.

Carburetting apparatus. M. Steel, Gosforth. U.S. Pat. 816,267, March 27, 1906.

SEE Eng. Pat. 10,677 of 1904; this J., 1905, 665.—T.F.B.

Gas generator. J. G. L. Bormann, Charlottenburg, Germany. U.S. Pat. 817,035, April 3, 1906.

THE gas generator comprises a shaft provided with a lower and an upper grate, and a reservoir around the

shaft. Channels connect the reservoir and shaft immediately above the lower grate, whilst air conduits leading from the outer air extend into and through the reservoir and discharge into the generator. The gases discharged through the lower grate are passed through a vaporiser where they generate steam in a spiral pipe, which steam is blown into the generator below the lower grate.—R. L.

Gas; Method of manufacturing ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 817,126, April 3, 1906.

MASSES of refractory material contained in a gas generator are heated, and subsequently hydrocarbons, preferably petroleum oils, are brought into contact with the coolest portion of the heated mass, the vapours being passed downwards from the cooler to the hotter portions of the refractory material. The condensable hydrocarbons produced are removed from the fixed gases (oil-gas), which are subsequently submitted to a high degree of heat by bringing them in contact with the hottest part of the refractory material. The vapours are thus partially decomposed with formation of solid carbonaceous matter, steam being simultaneously admitted for the purpose of decomposing and gasifying that carbonaceous matter. The water-gas generated thereby and the oil gas are then mixed. Two generators may be employed for the two operations of generating and decomposing the fixed gases.—R. L.

Gas washing device. L. P. Lowe, San Francisco, Cal U.S. Pat. 817,127, April 3, 1906.

THE gas-washing apparatus claimed, consists of a casing containing transverse partitions extending upwards from the bottom of the casing, and "washer-plates" as deflectors, extending downwards to a level below the tops of the partitions. There are double transverse walls between the partitions, and openings in the sides of the casing, through which removable boxes for collecting the tarry residues may be passed.—R. L.

FRENCH PATENTS.

Retorts for the complete distillation of coal; Vertical ——. H. W. Woodall and A. McD. Duckham. Fr. Pat. 359,762, Oct. 27, 1905.

SEE Eng. Pat. 21,447 of 1905; this J., 1906, 306.—T.F.B.

Briquettes; Process of treating —— to consolidate them, by carbonising the agglutinant soluble in water. B. Wagner. First Addition, dated Nov. 9, 1905, to Fr. Pat. 350,536, Jan. 5, 1905 (this J. 1905, 721).

THE briquettes are heated indirectly, by causing the flame to play upon the exterior of the walls of the channels through which the briquettes are passed, instead of, or as well as directly, by causing the flame or hot gases to pass over the briquettes. The hot gases may travel in the same, or in an opposite direction to that taken by the briquettes, and the forward movement of the latter is controlled by a spiral guide formed on the inner surface of the channels.—W. H. C.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 367.)

Lignite pitch; Distinction between —— and other pitches. E. Graefe. Chem.-Zeit., 1906, **30**, 298—299.

THE main differences between lignite pitch and other pitches examined by the author are illustrated in the following table:—

	Usual or average melting pt.	Residue left after extraction with benzene.	Sulphur.	Iodine value.
		Per cent.		
Lignite pitch	86°	0·0	2·14	93·7
Coal-tar pitch	91°—92°	46·0	0·31	50·0
Wool-fat pitch	32°	0·0	0·00	36·9
Stearine pitch	43°	0·0	0·67	40·4
Petroleum pitch I...	33°	2·0	1·17	49·4
Petroleum pitch II.	73°	3·5	1·09	70·3
Petroleum pitch III.	126°	4·0	1·00	103·5
Lignite "goudron"	52°	0·0	1·88	66·5
Wood pitch	195°	42·0	0·00	140·0

—D. B.

Petroleum spirit ("benzine") and its treatment. G. Polack. J. Gasbel, 1906, **49**, 337—343.

FROM the behaviour of petroleum spirit, stored in cans and other receptacles, in numerous cases of fire, the author recommends that storage barrels holding over 2 cwt. should be made of welded, riveted or brazed sheet metal, tested to stand a pressure of 2½ atmospheres, and fitted with fusible plugs to act as safety valves. No taps should be allowed, the vessels being emptied through the bunghole either by a siphon or pump, and means provided for returning to the storage vessel the air displaced by the oil entering the smaller receptacles, instead of allowing it to escape freely. Small vessels, up to ½ cwt. capacity, may be of soldered sheet metal, whilst those of intermediate size should be welded or brazed in the body with soldered conical tops and screw stoppers. Carboys should not be allowed at all, being very dangerous. The storage vessels should be protected from exposure to heat, and to this end underground tanks are preferred.—C. S.

Petroleum production; Russian —— in 1905. Oil and Col. J., April 28, 1906.

ACCORDING to returns issued by the Association of Baku naphtha producers, the total output of crude petroleum in the main district during 1905, comprising the Apsheron peninsula, amounted to 414,700,000 poods, as compared with 614,600,000 poods produced in 1904, and 596,600,000 poods in 1903. The great conflagrations in August were the primary cause of the considerable decline in the production. The output in June reached 46 millions of poods, and in July, 47 millions, but in August the production receded to 32 millions, and in September to only 2,100,000 poods. In October, however, it advanced to 18 millions, and in November to 24½ millions, but in December there was a fresh reduction to 19½ millions. The export of all classes of naphtha products amounted to 375 million poods in 1905, as compared with 492 millions in 1904. [T.R.]

Nitrotoluene; Detection and determination of —— in nitrobenzene, and of toluene in benzene. P. N. Raikow and F. E. Uerkewitsch. XXIII., page 446.

ENGLISH PATENTS.

Coke ovens with regenerator action. F. J. Collin, Dortmund, Germany. Eng. Pat. 10,699, May 22, 1905.

SEE Fr. Pat. 354,919 of 1905; this J., 1905, 1166.—T.F.B.

Coke ovens; Coking of coal in ——. The Otto-Hilgenstock Coke Oven Co., Ltd., London. From Dr. C. Otto and Co., G.m.b.H. Dahlhausen, Germany. Eng. Pat. 14,783, July 18, 1905.

IN coking coal or similar substances in ovens, the supply of heat to the walls of the oven is cut off when the outer portion of the charge within the oven has been coked, for the purpose of allowing the heat in this outer portion to be utilised in coking the yet uncoked core of the charge. This may be done either by inserting dampers in the waste-heat flue or by closing the main cock of the heating-gas pipe.—R. L.

Emulsions of heavy mineral oils or the like; Manufacture of ——. J. P. van der Ploeg, Amsterdam. Eng. Pat. 7699, April 11, 1905.

THE heavy hydrocarbons are, if desired, first mixed with some light hydrocarbon to reduce the density to nearly that of water, and heated with about 1 per 1000 of an "alkaloidal" base, such as quinoline or pyridine, enough of an inorganic or organic alkaline salt or base being added to produce a slightly alkaline reaction. This mixture will, it is stated, form a durable emulsion with water.—C. S.

GERMAN PATENTS.

Coal-tar oils; Process for preparing dermatologically active, high boiling ——, *which do not darken.* Knoll und Co. Ger. Pat. 166,975, 1903. XVIIIC, page 440.

Distilling apparatus for gas-liquor and the like. C. Francke. Ger. Pat. 165,309, June 5, 1904.

THE invention relates to a device for agitating the contents of the still, consisting of a shaft or the like provided throughout its length with stirring blades and caused to rotate by means of vanes arranged turbine-fashion, against which the heating steam is made to strike.—A. S.

Cylinder oils; Testing apparatus for ——. F. A. Adolphe Tayart de Borms. Ger. Pat. 165,870, July 3, 1904.

THE oil is allowed to drop into a test cylinder where it is subjected to the action of steam under the same conditions of temperature and pressure that it will be subjected to in practice. The decomposition products of the oil can be collected and examined.—A. S.

Paraffins; Process for obtaining wax-like —— free from oil, from mineral oils. W. H. MacGarvey and S. Stransky. Ger. Pat. 163,386, Aug. 9, 1904.

THE paraffin is separated from the mineral oil by draining, filtering or pressing at the ordinary temperature (about 20° C.), and is then pressed in hydraulic presses at a gradually increasing temperature till the adhering crystalline paraffins are removed.—A. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 370.)

Anthraquinone; Preparation of —— from benzoylbenzoic acid. G. Heller. Z. angew. Chem., 1906, **19**, 669—670.

THE charge consists of 1 kilo. of phthalic anhydride, 3·5 kilos. of benzene, and 1·8 kilos. of aluminium chloride. This mixture is introduced into a vessel lined with lead, provided with an agitator and a reflux apparatus, and heated by means of a hot water-jacket. At 30° C. evolution of hydrogen chloride commences, and as the temperature rises, the mass increases in viscosity, until it eventually becomes so thick that it stops the working of the agitator. When 70° C. has been reached, the heating is continued at that temperature, until the evolution of hydrogen chloride ceases. The mass is then cooled, diluted with 3 to 4 parts of water, the excess of benzene expelled by the introduction of steam, the residue rendered alkaline by the gradual addition of sodium hydroxide and boiled for several hours to decompose the aluminium compound into alumina and to form the sodium salt of benzoylbenzoic acid, from which the acid is obtained in the form of a crystalline mass by acidification. The yield is from 145 to 148 per cent. of the phthalic acid employed, being from 95 to 97 per cent. of the theoretical. The benzoylbenzoic acid is converted quantitatively into anthraquinone when heated with 5 to 6 parts of concentrated sulphuric acid for an hour at 150° C.—D. B.

Amino-p-dimethylaminobenzoic acid; The methyl ester of ——. F. Reverdin and E. Delétra. Ber., 1906, **39**, 971—974.

THE methyl ester of *p*-dimethylaminobenzoic acid is readily obtained by heating the acid for several hours with rather more than the theoretical quantity of methyl alcohol in presence of strong sulphuric acid on the water-bath. The ester is readily nitrated by adding it slowly to nitric acid of sp. gr. 1·34 at a temperature of 8°—12°C., this being finally allowed to rise to 16°—18° C. The yield is good. The mononitro compound formed, consists of yellow laminæ, melting at 71·5 C. It is reduced by tin and hydrochloric acid to the hydrochloride of amino-*p*-dimethylaminobenzoic acid methyl ester. The free base can be obtained by neutralising the aqueous solution of the hydrochloride with sodium carbonate, evaporating to dryness, and extracting the dry residue with alcohol. It is unstable in the air, and easily condenses with chlorodinitrobenzene. It is also readily diazotised in the usual manner, but the azo dyestuffs obtained from the diazo compound are not fast to washing or to soap, easily change colour, and possess no practical value. On adding the solution of the diazo-compound to a boiling aqueous solution of copper sulphate, hydroxy-*p*-dimethylaminobenzoic acid methyl ester is obtained, and can be isolated by adding sodium hydroxide in slight excess, filtering and then precipitating the hydroxy-compound with acetic acid. It melts at 176·5° C.—E. F.

Gallacetein of Nencki and Sieber, $C_{16}H_{12}O_6$; Synthesis of ——. C. Bülow and C. Schmid. Ber., 1906, **39**, 850—857.

IN 1881, Nencki and Sieber obtained "resaceteïn" by the action of zinc chloride on a mixture of resorcinol and acetic acid, or on resacetophenone; they also obtained "gallaceteïn" $C_{16}H_{12}O_6$, an isomeride of hæmateïn, by the action of zinc chloride on gallacetophenone (J. prakt. Chem. [2] **23**, 541). Bülow and Sautermeister (Ber., 1904, **37**, 354) have shown that resaceteïn is 2-(2.4.dihydroxyphenyl)-4-anhydromethyl-7-hydroxy[1.4-benzopyranol] (see this J., 1901, 704). The authors have now obtained trimethoxygallaceteïn by the condensation of pyrogallol with 2.3.4.trimethoxybenzoylacetone in presence of glacial acetic acid and dry hydrochloric acid gas, according to the equation:—

$$C_6H_3(OH)_3 + CH_3.CO.CH{:}C(OH).C_6H_2(OCH_3)_3 + HCl = (HO)_2C_6H_2{<}\begin{matrix}O\,(HCl)\,.\,C.C_6H_2(OCH_3)_3\\ C(:CH_2)\,.\,CH.\end{matrix} + 2H_2O.$$

By heating for 12 hours to 150°—180° C. in a sealed tube with concentrated aqueous hydrochloric acid, this forms the corresponding trihydroxy compound, 2-(2.3.4-trihydroxyphenyl)-4-anhydromethyl-7.8-dihydroxy[1.4-benzopyranol], identical with the gallaceteïn of Nencki and Sieber. This compound, in the form of its hydrochloride, shows the properties of a good mordant dyestuff. It yields more violet shades on chrome-mordanted wool than Alizarin Brown, and is quite as fast as the latter. The shades on alumina mordant are less fast, and bleed more. As the compound

$$(HO)\,C_6H_3{<}\begin{matrix}O\text{————}C\,.\,C_6H_2(OH)_3,\\ C(:CH_2)\,.\,CH\end{matrix}$$

an isomeride of Brasileïn, is not a good mordant dyestuff (Bülow and Schmid, Ber., 1906, **39**, 214), whereas gallaceteïn and the compound

$$(HO)_2C_6H_2{<}\begin{matrix}O\text{————}C\,.\,C_6H_5\\ C(:CH_2)\,.\,CH\end{matrix}$$

from pyrogallol and benzoylacetone, are typical mordant dyestuffs, the authors conclude that it is the hydroxyl groups in *o*-positions in the conjugated benzene nucleus of the benzopyranol group, and not the hydroxyl groups in the attached phenyl group, which confer the characteristic mordant-dyeing properties.—E. F.

Thionine and azoxine dyestuffs; Constitution of ——. F. Kehrmann. Ber., 1905, **39**, 914—926.

THE author replies to the criticisms of Hantzsch (this J., 1906, 173) and also describes fresh experiments, which support his own views as to the constitution of thionine and azoxine dyestuffs.—H. L.

English Patents.

Indophenolsulphonic acids; Production of ——. E. and E. Oehler, Offenbach a/Main, Germany. Eng. Pat. 7838, April 12, 1905. Under Int. Conv., Nov. 30, 1904.

See Fr. Pat. 352,200 of 1905; this J., 1905, 920.—T.F.B.

Indigo and similar colouring matters; Reduction of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 12,444, June 15, 1905.

See Addition of July 5, 1905, to Fr. Pat. 348,360 of 1904; this J., 1905, 1223.—T. F. B.

Colouring matters containing sulphur [Sulphide dyestuffs]; Manufacture of intermediate compounds and of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 15,763, Aug. 1, 1905.

See Fr. Pat. 357,600 of 1905; this J., 1906, 175.—T. F. B.

Dyestuffs; Manufacture of new anthraquinone —— *[Anthracene dyestuffs].* H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 12,756, June 20, 1905.

See Fr. Pat. 355,331 of 1905; this J., 1905, 1223.—T.F.B.

Dyestuffs; Manufacture of new sulphurised —— *[Sulphide dyestuffs].* C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 19,186, Sept. 22, 1905.

See Fr. Pat. 357,986 of 1905; this J., 1906, 175.—T. F. B.

United States Patent.

Dyestuff; Yellow Anthracene ——. M. Kugel, Wiesdorf, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 808,762, Jan. 2, 1906.

See Addition of Sept. 7, 1905, to Fr. Pat. 343,608 of 1904; this J., 1906, 260.—T. F. B.

French Patents.

Dyestuffs; Manufacture of black sulphide ——. L. Cassella and Co. Fr. Pat. 359,674, Jan. 30, 1905.

Tetra-amino-diphenyl-para-azophenylene (obtained by the oxidation of *p*-phenylenediamine) or its reduction product, is heated with sulphur. The product obtained is then heated with a concentrated solution of an alkali sulphide, which dissolves it, with the formation of a greenish-black sulphide dyestuff. The same product is obtained by heating the original substance with a polysulphide containing much sulphur.—A. B. S.

Dyestuffs; Process of making azo ——. Fabr de Coul. d'Aniline et d'Extraits ci-dev. J. R. Geigy. Fr. Pat. 359,858, Feb. 4, 1905.

See Eng. Pat. 2228 of 1905; this J., 1905, 964.—T. F. B.

Dianisidine and diphenetidine; Preparation of disulphonic acids of ——. Act.-Ges. f. Anilin fabr. Fr. Pat. 359,214, Nov. 7, 1905.

Disulphonic acids of *o*-dianisidine and *o*-diphenetidine are prepared by treating these substances with fuming sulphuric acid, care being taken to avoid an appreciable rise of temperature. The new substances contain a sulphonic acid group in each nucleus in the *p*-position to the alkoxyl group. Both are readily soluble in water, but the sodium salts are sparingly soluble and crystallise well.—H. L.

o-Hydroxyazo dyestuffs; Production of ——. Fabr. de Prod. Chim. ci-devant Sandoz. Fr. Pat. 359,222, Nov. 7, 1905.

Diazotised *o*-aminophenol derivatives are combined with aryl-1.8-naphthylaminesulphonic acids. The new dyestuffs produce reddish-brown to violet shades on wool from an acid bath, which turn to black or dark blue on subsequent treatment with bichromate or copper sulphate. The shades after such treatment are stated to possess extraordinary fastness to light, acids, alkalis and milling. Among the *o*-diazophenols suitable are the diazo compounds of mono- and dichloro-*o*-aminophenol, mono- and dinitro-*o*-aminophenol, chloro-nitro-*o*-aminophenols, nitro-*o*-ammocresols, *o*-aminophenolsulphonic acids, their homologues and substitution products. The combination of *o*-nitro-*o*-amino-*p*-cresol with 1.8-phenylnaphthylaminesulphonic acid and of chloro-*o*-ammophenol-*o*-sulphonic acid with 1.8-*p*-tolylnaphthylaminesulphonic acid is described in detail. The first dyestuff produces brownish-violet shades on wool, which turn to intense blue-black on treatment with bichromate or copper sulphate. The latter dyes wool a reddish Bordeaux, which, on treatment with copper sulphate, changes to a rich violet-blue and on chroming to a dark blue. Combination is effected in slightly alkaline solution.—H. L.

Sulphurised organic compounds; Preparation of —— *and their utilisation for the production of a red dyestuff [Thioindigo Red].* Kalle und Co. Fr. Pat. 359,398, Nov. 13, 1905.

The preparation and properties of phenylthio-glycol-*o*-carboxylic acid, thioindoxyl-*o*-carboxylic acid, thioindoxyl, and a red dyestuff having probably the formula,

$C_6H_4<\begin{matrix}CO\\S\end{matrix}>C:C<\begin{matrix}CO\\S\end{matrix}>C_6H_4$, are described (see this J., 1906, 367). Phenylthioglycol-*o*-carboxylic acid is formed (1) by condensing thiosalicylic acid $C_6H_4(SH)COOH$ (1:2) with chloroacetic acid; (2) by combining diazotised anthranilic acid with thioglycollic acid. In the latter process, a substance of the formula, $C_6H_4(COOH).N_2.S.CH_2COOH$, is obtained as the first reaction product, which gives off nitrogen when heated in neutral, acid, or alkaline solution, and is converted with good yield into phenyl-thioglycollic-*o*-carboxylic acid. A white crystalline product of excellent purity is, it is stated, directly obtained. The evolution of nitrogen takes place at a temperature of 20°—25° C. in the presence of finely divided copper. Phenylthioglycollic-*o*-carboxylic acid is almost insoluble in cold water, but easily soluble in aqueous alkalis, and crystallises well from dilute alcohol; m. pt. 213° C. On heating with (or without) the addition of condensing agents such as caustic alkalis or acetic anhydride, it is converted into thioindoxyl-carboxylic acid. This substance is only stable in cold, neutral or alkaline solution. When heated, it loses carbon dioxide and is readily converted into thioindoxyl, especially in the presence of acids. By oxidising agents thioindoxylcarboxylic acid is converted into a red dyestuff. It is sparingly soluble in cold water, but dissolves in aqueous alkalis. On acidifying the solution, it is obtained as a yellowish-white crystalline product, which gradually turns red on exposure to the air or to light. Thioindoxyl is characterised by the great facility with which it is converted into a red dyestuff by contact with oxidising agents or the air. It is readily volatile in steam. The smell is similar to that of naphthol. The new dyestuff dissolves in chloroform to a red solution, possessing a beautiful yellow fluorescence, but is insoluble in the usual solvents. It is soluble in reducing agents such as sodium sulphide, hydrosulphite (hyposulphite), &c., forming a yellow solution from which the colouring matter is regenerated by oxidation. Fourteen examples are given to illustrate the various processes.—H. L.

Dyestuff; Process for the preparation of a red sulphurised —— *[Thioindigo Red].* Kalle und Co., Fr. Pat. 359,399, Nov. 13, 1905.

The preparation of the red sulphurised dyestuff (see preceding abstract) by treating thioindoxyl or analogous combinations with oxidising agents or with a current of air, is illustrated by four examples.—H. L.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 373.)

Bleaching of Wool; Process of ——. Thierry-Mieg and Co. Bull. Soc. Ind. Mulhouse, 1906, **76**, 47—49.

THE scouring with soap is replaced by treatment with sodium carbonate, thus avoiding the formation of calcareous soaps which are objectionable in printing. For muslin, the operations are:—(1) Treatment for thirty minutes in water at 40°C., 2000 grms. of sodium bicarbonate, or the equivalent of soda crystals, being added for six pieces; (2) rinsing during thirty minutes in water at 0°; (3) passing through a solution of sodium bisulphite of 6° B.; (4) steaming, under pressure, for three-quarters to one minute; (5) rinsing in cold water. A. Law and C. Binder, in a report to the Society, state that treatment with sodium carbonate may perfectly replace soaping, but they find that a brief treatment with bisulphite followed by steaming never gives so pure a white as a prolonged immersion in bisulphite alone, of the same degree of concentration. For the rapid production of a white as a ground for printing, the process, however, is of interest.—B. N.

Sulphide dyestuffs; Applications of ——. J. Heilmann and Co., and M. Battegay. Bull. Soc. Ind. Mulhouse, 1906, **76**, 50—54.

THE communication relates to the application of sulphide dyestuffs in printing, and the fixing of these colours by the aid of caustic soda and hydrosulphite (hyposulphite-) glycerin. The colour is dissolved by mixing and heating with sodium hydrosulphite, made into a paste with glycerin and caustic soda of 36° B. To assist the fixing of the dyestuff on the fibre, kaolin, a saturated solution of salt, and alkaline thickening, the latter consisting of caustic soda of 38° B. and gum water is added, after cooling. On red and claret grounds, the dyestuff is also mixed with hydrosulphite-formaldehyde. To discharge the colour, hydrosulphite-glycerin, mixed with kaolin, saturated salt solution and alkaline thickening is used, or, in the case of red and claret grounds, hydrosulphite-formaldehyde and gum water. The printed fabrics are steamed for five or six minutes in the Mather-Platt. In another report, C. Favre states that with certain dyestuffs the presence of glycerin appears to be indispensable, and in general gives purer tints, but does not offer any advantage over hydrosulphite-formaldehyde as far as the destructive action on the copper rollers is concerned. In printing with two colours, say black and blue, it does not prevent the inconvenience (though the new process lessens it) of the roller which prints the blue being attacked where it presses down on the black colour.—B. N.

Discharges and half-discharges on wool with potassium sulphite. J. Heilmann and Co. and M. Battegay. Bull. Soc. Ind. Mulhouse, 1906, **76**, 55—57.

POTASSIUM sulphite is used in calico printing in order to obtain half-discharges, the latter being secured by a passage through a Mather-Platt, or by a continuous steaming for half to three-quarters of an hour, under pressure, a clear white may be obtained. By using a mixture of dyestuffs, one of which is discharged by hydrosulphite- (hyposulphite-) formaldehyde, but sufficiently resistant to potassium sulphite, and by printing with this latter, both coloured and white discharges may be obtained by over-printing with hydrosulphite-formaldehyde. In a further report, O. Michel confirms the results which have been obtained by the authors.
—B. N.

Drying of printed pieces; Note on the ——. E. Boeringer. Bull. Soc. Ind. Mulhouse, 1906, **76**, 17—37.

THE author states that drying by steam plates is more economical as regards fuel than drying by hot air, but the best method is to pass the fabrics over drums heated by hot water, the hot water being heated by exhaust steam. Drying by means of plates or hot air combined with electrical driving of the machines, is not to be recommended, but, with electrical power at hand, the driving of machines by its aid, and the drying of the pieces by hot water heated with steam may be used with advantage in new installations. The economy resulting from this arrangement, however, is stated not to justify the transformation of an existing plant using the older process.

ENGLISH PATENTS.

Wool; Extraction of grease from —— and apparatus therefor. A. H. Burt, Mosman, H. Jackson and C. A. Finch, Sydney, N.S.W. Eng. Pat. 10,691, May 22, 1905.

SEE Fr. Pat. 354,667 of 1905; this J., 1905, 1107.—T.F.B.

Textile fabrics; Apparatus for washing ——. H. H. and T. S. Shuttleworth, Edenfield, Lancaster. Eng. Pat. 12,545, June 17, 1905.

THE material is repeatedly squeezed or beaten between a revolving drum and a curved surface or block arranged in an endless channel or trough, in which it travels round and round. The drum is arranged within a casing or box something after the manner of a paddle-wheel, and as the material clears the block both it and the water mingled with it are thrown forcibly against the casing, which is fitted with a grid or strainer. It is found that as the material as it is thrown sidewise and upwards tangentially from the drum, falls more quickly than the water, and so the two separate by the centrifugal force, and follow divergent paths, the water being uppermost. Thus the grid or strainer can be arranged so that only the water strikes upon it, the material falling back into the trough for a fresh passage under the wheel, whilst the dirty water passes out through the strainer.—D. B.

Fabrics; Method and means for winding —— in continuous bleaching apparatus, applicable also to other purposes. M. Muntadas y Rovira, Barcelona, Spain. Eng. Pat. 6160, March 23, 1905. Under Int. Conv., March 23, 1904.

FRENCH PATENTS.

Red shades [Thioindigo Red] on animal or vegetable fibres; Production of ——. Kalle und Co. Fr. Pat. 359,400, Nov. 13, 1905.

THE red sulphurised dyestuff described in Fr. Pats. 359,398 and 359,399 (see page 424) is fixed on animal or vegetable fibres by means of the leuco solution. Bright bluish-red shades are produced which are very fast to water, acids, alkalis, washing, milling, soaping and light and remarkably fast to chlorine.

Example.—The dyestuff in the form of a 20 per cent. paste is treated with the necessary amount of sodium sulphide, sodium carbonate and common salt, or of hydrosulphite (hyposulphite) and caustic soda to form a yellowish solution, which only oxidises slowly on the surface. Cotton is introduced into the dye-bath and dyed at 80° C., or at the ordinary temperature. After dyeing the goods are squeezed and hung out in order to reoxidise the leuco compound.

Wool may be readily dyed in heavy shades from a weakly alkaline hydrosulphite vat, the leuco body possessing great affinity for the fibre. In general any method in use for dyeing indigo, such as the fermentation vat process, can be employed. For calico printing the following are two of the recipes given:—*Printing colour A.*—350 grms. of British gum, 3:2; 500 grms. of caustic soda of 40° B.; 150 grms of 20 per cent. dyestuff paste. *Printing colour B.*—400 grms. of British gum, 3:2; 350 grms. of caustic soda of 40° B.; 70 grms. of hydrosulphite NF; 200 grms. of 20 per cent. dyestuff paste. Colour A may be printed on cloth prepared with glucose, but this is stated to be not essential. After printing, the goods are dried, steamed for two to four minutes, washed in running water to regenerate the dyestuff from the leuco body, soured, washed and dried.

The claims embrace the processes described for dyeing and printing, and also, as new articles of manufacture, the dyed and printed tissues.—H. L.

Copper cylinders; Process for engraving ——for use in printing cretonnes, &c. The Calico Printers' Association, Ltd. Fr. Pat. 359,759, Oct. 24, 1905. Under Int. Conv., Dec. 14, 1904.

Chamber process [Sulphuric acid]; Position of the fan in the ——. G. Schliebs. Z. angew. Chem., 1906, **19**, 671—672. (See this J., 1905, 1301.)

A REPLY to Niedenführ (this J., 1906, 120).—D. B.

Chloric acid; Preparation of pure —— and its application as an oxidising agent. V. Bernard. Ann. Chim. anal. appl., 1906, **11**, 81—82.

EIGHT hundred grms. of pure barium chlorate are dissolved in 1700 c.c. of hot distilled water; the solution is filtered into a capacious flask, and, when cold, treated with 243 grms. of sulphuric acid of sp. gr. 1·847, diluted with sufficient water to make about 2 litres of liquid; this is added to the barium chlorate solution in successive small quantities with thorough agitation, care being taken to obviate rise of temperature, as otherwise the acid formed will be oxidised to perchloric acid. After mixing, the barium sulphate is allowed to deposit, and the supernatant liquid is filtered through asbestos. About 1750 c.c. of chloric acid of sp. gr. 1·11 at 20° C. are thus obtained, containing only a trace of free sulphuric acid.

This acid is a valuable oxidising reagent, usefully replacing nitric acid or potassium chlorate in many analytical processes. It is specially useful in the determination of tin in brass and bronze by Hollard's electrolytic method, and for the oxidation of chromium salts in Storer's process.—J. O. B.

Phosphomolybdic acid; Behaviour of —— towards ether. A. Verda. Chem.-Zeit., 1906, **30**, 329—330.

WHEN the ordinary phosphomolybdic reagent (5 parts of phosphomolybdic acid, 7 parts of nitric acid, 100 parts of water) is shaken with excess of ether, it is decolorised, the colour becoming concentrated in a small quantity of dense liquid which separates at the bottom of the vessel. This proved to be a solution of phosphomolybdic acid in ether, for on evaporation of the ether there remained pure phosphomolybdic acid as an amorphous yellow powder, more readily reducible than the ordinary phosphomolybdic acid. Pure water dissolves out the phosphomolybdic acid from the yellow liquid, but water saturated with ether is without action on it. Ether forms with solid phosphomolybdic acid this yellow liquid, which, however, does not mix with the excess of ether. Solutions of phosphomolybdates, acidified and treated with ether, can in this way be made to yield pure phosphomolybdic acid.—J. T. D.

Bleaching powder; Constitution of ——. W. von Tiesenholt. J. pr. Chem., 1906, **73**, 301—326.

THE author maintains his view (this J., 1902, 913) that bleaching powder is the product of a reversible reaction between chlorine and lime; that other metallic oxides do not yield similar bleaching compounds is due to the different characters of the oxides and the corresponding chlorides. The reversed reaction (evolution of chlorine from the bleaching compound) occurs only in presence of water, and is due to the hypochlorous acid formed

by hydrolysis of the hypochlorite; the reaction of carbon dioxide upon bleaching powder also depends on the liberation in the first place of hypochlorous acid, the carbon dioxide neutralising the calcium hydroxide simultaneously formed. The same reactions are undergone by mixtures of calcium chloride and hypochlorite and of calcium chloride and lithium hypochlorite; calcium chloride is peculiarly well adapted to show this reaction because of its special properties in regard to water of crystallisation. While the existence in bleaching powder of the compound Cl.Ca.OCl is highly probable (though not proved), other complex compounds of calcium chloride and hypochlorite also exist in it. Chlorine monoxide reacts on lithium chloride and on calcium chloride, but only when water of crystallisation is present, and therefore, no doubt, by the formation in the first instance of hypochlorous acid. Hypochlorites, in the absence of water and in presence of free bases, are moderately stable compounds: mercuric hypochlorite can be obtained, for example, by the action of chlorine on mercuric oxide.—J. T. D.

Cyanogen and hydrogen cyanide; Synthesis of —— from their elements. T. Wallis. Annalen, 1906, **345**, 353—362.

THE author finds that the statements in text-books to the effect that cyanogen is formed by the interaction of carbon and nitrogen under the influence of the electric arc or electric sparks, is incorrect; any cyanogen produced, owes its formation to decomposition of hydrogen cyanide, formed primarily from nitrogen and hydrogen or water vapour. For the detection of cyanogen in presence of hydrogen cyanide, the use of an acidified (with nitric acid) solution of silver nitrate is recommended. The hydrogen cyanide is absorbed, whilst the cyanogen passes through almost completely. Any traces of cyanogen retained by the silver solution can be detected by filtering off the silver cyanide, separating silver from the filtrate by yellow ammonium sulphide, evaporating the solution, and testing the residue with a drop of sodium hydroxide solution for thiocyanate.

For quantitative purposes, the decomposition of cyanogen by alkali may be utilised. The mixture containing cyanogen and hydrogen cyanide is passed through standardised alkali: $(CN)_2 + 2KOH = KCN + KCNO + H_2O$. The total cyanide is then determined by titration with silver solution, and the cyanate by boiling a separate portion with dilute sulphuric acid and estimating the ammonia produced.—A. S.

Sulphuric acid; Electric conductivity of dilute solutions of ——. W. C. D. Whetham. XII., page 432.

Zinc and hydrochloric acid; Purification of —— from arsenic. L. T. Thorne and E. H. Jeffers. X., page 430.

ENGLISH PATENT.

Sulphocyanides [Thiocyanates]; Manufacture of ——. J. Tchernıac, London. Eng. Pat. 2708, Feb. 3, 1906.

CRUDE coal-gas, previously purified from ammonia, but still containing sulphuretted hydrogen, is passed systematically through a mixture of slaked lime and sulphur with water, until the free sulphur has entered into combination. The filtered liquid contains calcium thiocyanate. A salt capable of double decomposition with calcium thiocyanate may be added to this mixture of lime and sulphur previous to the described treatment, in order to obtain another thiocyanate. Also, the lime used may be slaked with the washing water, or with a solution of the salt to be added, in the case specified. Eng. Pat. 22,710 of 1902 (this J., 1903, 212) is referred to.—E. S.

UNITED STATES PATENTS.

Sulphuric acid; Process of making ——. R. Knietsch, Ludwigshafen-on-Rhine, Germany, Assignor to General Chemical Co., New York. U.S. Pat. 816,918, April 3, 1906.

SEE Eng. Pat. 6829 of 1901; this J., 1902, 344.—T. F. B.

Ammonia; Process of producing —— [electrolytically]. J. A. Lyons and E. C. Broadwell, Chicago, Ill. U.S. Pat. 816,928, April 3, 1906.

THE borate of an "electropositive metal" is fused and subjected to electrolysis, the anode being separated from the cathode by a jacket of resistive material. The boric anhydride produced is reduced to boron at the anode by the action of a reducing agent and "an intense heat," the boron is converted into nitride by means of nitrogen introduced between the anode and the jacket, and the nitride is subjected to the action of steam at a sufficient temperature to decompose it with formation of ammonia and boric anhydride.—A. S.

FRENCH PATENT.

Pyrites; Process of preparing —— for desulphurisation. U. Wedge. Fr. Pat. 359,767, Nov. 6, 1905.

SEE U.S. Pat. 804,690 of 1905; this J., 1905, 1302—T. F. B.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 374.)

ENGLISH PATENT.

Glass; Apparatus for drawing ——. J. A. Chambers, Allegheny, Pa. Eng. Pat. 2879, Feb. 6, 1906. Under Int. Conv., Feb. 15, 1905.

THE plant described consists of a tank, at the end of which is an overflow, by which glass flows into pots made of refractory material and mounted upon a rotating table. The larger portion of the table is within the pot chamber, and the smaller portion within the drawing chamber. Glass is allowed to flow into one pot, and the table is rotated far enough to bring the second pot under the overflow, while the first is carried round, and the glass in it kept molten by the heat of the pot chamber. By rotating the table further, this pot is brought into the drawing chamber, while a third pot is brought under the overflow and filled. After drawing the article from the glass in the first pot, through an opening in the roof of the drawing chamber, the table is rotated further, so that the second pot of glass is brought into the drawing chamber, and a fourth pot brought below the tank overflow to be filled, and the first pot from which the glass has been drawn, passes back into the pot chamber, where the hardened residue left in it is remelted before it is again filled with glass from the tank at the next rotation of the table.—W. C. H.

Plastic material; Method of treating ——. A. A. Scott, Knoxville, Tenn. U.S. Pat. 816,385, March 27, 1906.

A STREAM of the plastic material is severed into blocks, which, in the green state, are placed in groups in one compartment of a kiln. Each group is surrounded by plates of combustible material or by a flash-wall of previously-dried blocks, and is dried by the action of a horizontally moving current of heated gases at a moderate temperature. The combustible material or flash-wall is then destroyed, another group of green blocks placed on the first and these dried, and finally all the blocks are fired at a high temperature. The waste heat from the firing of the blocks in one compartment serves for the drying of the green blocks in one of the other compartments.—A. G. L.

Plastic material ; Method of treating ——. A. A. Scott, Knoxville, Tenn. U.S. Pats. 816,386 and 816,387, March 27, 1906.

THESE two patents differ from the preceding only in the arrangement of the groups of green blocks within the compartments of the kiln for the purposes of drying. The groups may either be set with vertical flue-spaces between them, through which hot gases rise and are then deflected horizontally through the groups of blocks, or else moderately heated air is forced into the base of a mass of blocks and then distributes itself around and between them.—A. G. L.

FRENCH PATENT.

Tiles, glass, porcelain, ceramic products and the like ; Apparatus for burning or fixing the colours on printed ——. L. W. Stanley. Fr. Pat. 359,904, Nov. 28, 1905.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 375.)

Cements ; Decomposition of —— in sea-water or waters containing calcium sulphate. H. le Chatelier. Bull. Soc. d'Encourag., Revue de Metall., 1906, **3**, 74—77.

THE author finds that the addition to a cement of 2 per cent. of calcium stearate does not retard the action of sea-water upon it, whilst it sensibly reduces the tensile strength of cement-sand mixtures. The permeability to water of the set cement is but slightly reduced by the addition of calcium stearate.

The addition of barium carbonate (with the view of decomposing calcium sulphate and preventing the formation of calcium sulpho-aluminate) was also found to be but slightly operative, except with a slag-cement, in retarding disintegration by sea-water ; probably the barium sulphate formed is not voluminous enough to reduce sensibly the porosity of the cement.—J. T. D.

Slag cement and sea-water. Maynard. Tonind-Zeit., 1906, **30**, 440 ; Chem.-Zeit., 1906, **30**, Rep. 125.

To test the hypothesis that cements containing an insufficient amount of lime to form sulphaluminates are the best for use in sea-water, slag cement was taken, and mixed with varying proportions of lime. The results showed that the sample poorest in lime behaved the best, being as good as Portland cement and far superior to hydraulic lime. An important point is to store the blocks, before immersing them in sea-water, a sufficient time to enable the lime to combine with silica. Though decomposition may not be entirely precluded, the changes will not be accompanied by an increase in volume if the cement has been properly compounded.—C. S.

ENGLISH PATENTS.

Dustless roads and like surfaces ; Process and apparatus for the manufacture of materials for the construction of ——. W. Freakley, Hanley, and R. Bill, Stoke-on-Trent. Eng. Pat. 19,686, Sept. 29, 1905.

MATERIALS for the construction of dustless roads and like surfaces, are prepared by saturating crushed furnace slag (or other suitable crushed or granular mineral material) with tar, creosote, or other suitable bituminous substance or solution, in a heated state, by the application of heat and atmospheric pressure, by means of the apparatus described. The apparatus comprises a vessel, or saturator, provided with an air-tight removable cover at one end, the other end being convex. The saturator is mounted on trunnions and can be turned in any required position, in one plane. Below the lower end of the saturator is a tar boiler, heated by a suitable furnace, so placed that heat from it also heats the saturator. A delivery pipe, provided with a regulating valve, leads from the boiler into the saturator, through one of the trunnions, and the other trunnion is connected with an exhausting apparatus, provided with suitable safety-valves. The process is as follows :—Granulated material, previously heated to expel moisture from its pores, is charged into the saturator, while still hot, and the air-tight cover replaced. The saturator, heated by the tar boiler furnace, is then exhausted, to remove air, &c., from the granulated material, and by opening the regulating valve on the tar-delivery pipe, a certain amount of tar is driven into the saturator by atmospheric pressure. Air, compressed or not, is then admitted to the saturator, to force the tar into the pores of the granular material, and the saturator revolved to ensure the proper coating of the particles of the charge with tar. Any surplus tar is then poured off through a valve on the cover of the saturator, and the charge removed.—W. C. H.

Solid forms, such as rods, tubes, discs ; Manufacture of —— with aid of silicon. A. G. Bloxam, London. From Gebr. Siemens und Co., Berlin. Eng. Pat. 26,384, Dec. 18, 1905.

A MASS containing silicon, associated with silicon carbide, preferably, or with carbon, or other suitable material, is moulded, by aid of an agglutinant, if necessary, into the desired form, as, for instance, of rods, tubes or discs. These forms are heated for a considerable time in an atmosphere of nitrogen, whereby a nitrogenised compound is obtained which, in case carbon or a carbonaceous agglutinant, such as coal tar, is used in the composition, consists mainly of the compound, C_2Si_2N, which firmly cements the silicon carbide present. The rods or other forms thus produced are stated to endure heating to a high temperature in contact with the air, without change ; to be dense, conductors of electricity, and so hard as to be suitable for application as a substitute for carborundum for grinding purposes.—E. S.

Silicon monoxide [Pigment, &c.] ; Manufacture of ——. H. N. Potter. Eng. Pat. 26,788, Dec. 22, 1905. XIII.A., page 434.

Cement-burning furnace. W. E. Snyder, Nazareth, Pa. U.S. Pat. 816,753, April 3, 1906.

THE furnace consists of a rotatory annular hearth fitted with a reverberatory hood, in which are a number of arc

electrodes, placed so that the arcs sweep across the entire extent of the hearth. Draught-compelling means are also provided which produce a current of air in opposition to the direction of movement of the hearth. A feed and discharge aperture is also provided in the hood, and a scraper is placed above the hearth in the aperture.
—A. G. L.

Cement; Apparatus for manufacturing ——. C. Ellis, Assignor to Combustion Utilities Co., New York. U.S. Pat. 817,163, April 10, 1906.

Two rotatory kilns are placed side by side, with the upper end of one opposite the lower end of the other. A gas-producer is placed at the lower end of each kiln and a chimney-stack at the upper end. By means of two pipe connections a determined amount of waste gases from each stack is introduced into the producer opposite, together with a determined amount of air. Means are supplied for burning in each kiln the gas produced in its producer. Each stack is fitted with an air-heater, and each kiln with a heating-stove, and means are provided for conveying the air heated in each stack through a stove and thence to the opposite kiln to assist in burning the gas, as well as means for introducing regulated amounts of the products of combustion from the stoves into the pipe connections.—A. G. L.

FRENCH PATENTS.

Bricks; Process for covering —— with a protective coating to prevent efflorescence and blackening. M. Perkiewicz. Fourth Addition of Nov. 7, 1905, to Fr. Pat. 330,655 of Mar. 27, 1903 (this J., 1903, 1088; 1904, 19 and 602; 1905, 30).

THE bricks are covered with a strong solution of glue free from starch-paste, &c. Disinfectants, such as acids, metallic salts, formalin and phenol are added to the glue.

GERMAN PATENTS.

Wood; Process for the manufacture of artificial ——. E. Helbing. Ger. Pat. 165,582, Nov. 27, 1903.

THE process described in Ger. Pat. 128,728 of 1900 (see Eng. Pat. 13,136 of 1901; this J., 1901, 991 and U.S. Pat. 694,014 of 1902; this J., 1902, 479) is modified by substituting barium hydroxide or strontium hydroxide, or a mixture of the two, for a portion or the whole, of the slaked lime.—A. S.

Wood; Process for fixing and improving the colour of impregnated or dyed ——. G. Hammesfahr. Ger. Pat. 166,388, June, 4, 1904.

THE wood after being dyed or impregnated is boiled with a mixture of slaked lime, rape oil or other oils or animal fats, and water.—A. S.

X.—METALLURGY.

(*Continued from page* 379.)

Ferromolybdenum; Pure ——. E. Vigouroux. Comptes rend., 1906, **142**, 889—891.

BY reducing a mixture of pure oxides of iron and molybdenum by aluminium in deficit, or by direct fusion of a mixture of pure iron and molybdenum reduced by hydrogen from their oxides, the authors have produced a series of alloys containing up to 80 per cent. of molybdenum. These have yielded the four definite compounds, Fe_2Mo, Fe_3Mo_2, FeMo, and $FeMo_2$; they are grey crystalline bodies, formed with considerable contraction of volume, non-magnetic, insoluble in hydrochloric but soluble in nitric acid. No compound was found containing less molybdenum than Fe_2Mo; from alloys of lower molybdenum-content hydrochloric acid dissolves out iron and leaves the compound, Fe_2Mo.—J. T. D.

Zinc-box precipitates; Production of high-grade gold bullion from ——. C. J. Morris. Inst. of Min. and Met., April 19, 1906. [Advance proof.]

THE author describes and compares the methods employed and the costs of producing gold bullion at the Myalls' United Mines five or six years ago and now. Formerly, the zinc was scrubbed and the slimes and fine zinc shreds were rubbed through a 40-mesh sieve, that which remained on the sieve being returned to the boxes, whilst that which passed through was roasted in an open pan for five or six hours over a wood fire, with the addition of about 5 per cent. of nitre. The roast was removed from the pan, mixed with about 50 per cent. of borax, 25 per cent. of sodium carbonate, and 12½ per cent. of sand, and fused in plumbago pots in a wind furnace, yielding bullion about 500 fine. The slags assayed from 30 to 70 oz., they were ground up with sweepings, &c., in a Berdan pan, leaving tailings assaying from 15 to 20 oz. Much gold was left in the boxes, sometimes twice as much as was obtained in the clean-up.

The present method is to scrub all the zinc except the fine shreds which, together with the slimes, are placed in an acid tank built of Oregon pine about 5 ft. deep and 4 ft. diam., provided with a four-armed revolving paddle and having plugged holes at intervals for drawing off the wash, and a locked cover. About 20 lb. of sulphuric acid are added from time to time as is found to be required, and the mixture of slime and dilute acid is left at rest all night. In the morning, all effervescence having ceased, about 12 times the bulk of water is added, while the slimes are agitated. After again resting, the wash water is drawn off into a settler and is found to contain only 1 to 2 dwt. of gold to the ton—most of which is recovered by prolonged settling. The washed slimes are removed, dried with about 5 per cent. of nitre, roasted, fluxed with 60 per cent. of assay slag, 20 per cent. of nitre and 5 per cent. of fused borax, and fused in Battersea clay pots; the bullion thus obtained is from 940 to 950 fine. The total cost of the operation by the former method yielding bullion 550 fine was £9 4s., of the present method yielding bullion 930 fine is £5 18s.; the freight and bank charges will, of course, be lessened in proportion to this difference of fineness. The value left in the zinc boxes is reduced by at least £250.—J. H. C.

Nickel silicides. W. Guertler and G. Tamman. Z. anorg. Chem., 1906, **49**, 93—112.

FROM a study of the alloys of nickel and silicon including the preparation of the melting-point diagram, and also micrographic examination, the existence of five compounds, Ni_3Si, Ni_2Si, Ni_3Si_2, NiSi and $NiSi_2$, was proved. The compounds Ni_2Si and NiSi separate directly from the melts on cooling, but the formation of the compound, $NiSi_2$, is due to a secondary reaction between primarily separated crystals of silicon and the residual melt. The two other compounds, Ni_3Si and Ni_3Si_2, are formed by secondary reactions between different kinds of mixed crystals in presence of the liquid melt; the first-named, Ni_3Si, from the two kinds of saturated mixed crystals containing 16·0 and 26·5 atoms per cent. of silicon respectively, and the latter, Ni_3Si_2, from the series of mixed crystals containing from 33 to 37·5 atoms per cent. of silicon.

The alloys containing 5·10 and 15 atoms per cent. of silicon, respectively, can be worked easily when cold, but not at a red heat. Alloys containing up to 22 atoms per cent. of silicon will withstand repeated blows, but as the proportion of silicon rises beyond 22 atoms per cent., the brittleness increases rapidly, and the alloy with 25 atoms per cent. of silicon breaks easily into thin plates. Alloys

containing from 50 to 75 atoms per cent. of silicon can be easily pulverised. The alloys containing up to about 20 atoms per cent. of silicon show a different degree of hardness according to whether they are cooled slowly or quenched. Their behaviour in this respect is exactly the reverse of that of carbon steels, the hardness decreasing if the alloys are quenched. The alloy containing about 15 atoms per cent. of silicon is the hardest when slowly cooled and the softest when quenched, but the difference in hardness according to the method of cooling is not so great with higher percentages of silicon. The softest alloys are those containing between 60 and 70 atoms per cent. of silicon.—A. S.

Auriferous tin-stone; Assay of ——. C. O. Bannister. Inst. of Min. and Met., April 19, 1906. [Advance proof.]

FIVE methods were employed, *viz.*:—(1) Scorification assay followed by cupellation; (2) crucible assay and cupellation; (3) solution in *aqua regia*, precipitation of gold by ferrous sulphate, and cupellation; (4) concentration of the gold in part of the tin by ordinary crucible assay, using anthracite, solution of the tin button in hydrochloric acid, and cupellation of the residue; (5) collection of the gold in the whole of the tin by fusion with potassium cyanide followed by solution of the tin and cupellation. For ores containing up to 26 oz. of gold to the ton convenient quantities to be taken are:—(1) 5 grms., (2) 25 grms., (3) 25 to 50 grms., (4) 25 grms., (5) 10 grms. It was found that the scorification method (1) always gave low results, the crucible assay (2) gives excellent results, the wet method (3) is tedious and gives good results as to the gold but loses the silver, methods (4) and (5) give low results and are unreliable for silver.—J. H. C.

Tin-dressing; Use of the impact screen in ——. J. H. Collins. Inst. of Min. and Met., April 19, 1906. [Advance proof.]

AT Wheal Kitty, in Cornwall, about two tons of tin-stuff per hour are crushed with old-fashioned Cornish stamps to pass a 20-mesh screen of which 25·5 per cent. remains on a 30-mesh, 40 per cent. passes 30-mesh and remains on 60, 13·5 per cent. passes 60 and remains on 80, 21·5 passes 80-mesh and 2 per cent. is fine slime. The slime and most of the fine sand which passes through 80-mesh are removed for separate treatment by hydraulic separators, and the remainder of the pulp is fed on to four Wilfley tables. The "heads" and "middlings" from these tables are removed for separate treatment, while the "tails," about 1¼ tons per hour, are passed over the screen, which is of 60-mesh brass wire cloth, 3 ft. square, inclined at an angle of 45°, and operated by a cam wheel giving 300 taps per minute. The over-screen product usually assays less than 0·1 per cent. of tin oxide, that passing through containing from 0·3 to 0·6 per cent., which is very easily and cheaply recovered by buddling and framing. The wear and tear of the screen is trifling, as is also the power required for operating the screen.—J. H. C.

Zinc and hydrochloric acid; Purification of —— from arsenic. L. T. Thorne and E. H. Jeffers. Analyst, 1906, **31**, 101—103.

THE conditions under which arsenic may be removed from zinc by means of sodium are described (see this J., 1902, 675). Commercial zinc is melted in a crucible at a temperature just above its melting point, and is then treated with sodium, the latter being added in small pieces at a time, until 1 grm. per pound of metal has been introduced. The zinc is now poured into a second heated crucible and back again once or twice; the crucible with its lid on is then heated to dull redness, the lid is removed and the heating continued for one hour, care being taken that the temperature does not rise much. The crust which forms is now pierced and the molten metal poured into another heated crucible and skimmed if necessary. This crucible and its contents are next heated to bright redness, skimmed, cooled and the zinc granulated just before the solidifying point is reached.

The authors have employed a copper-tin couple for removing arsenic from hydrochloric acid with complete success. Redistilled hydrochloric acid is diluted to a specific gravity slightly under 1·1 and then poured on to the couple which is conveniently prepared by dissolving cuprous chloride in excess of hydrochloric acid and adding a small quantity of granulated tin. The tin rapidly dissolves, at the same time reducing some copper in a spongy form. Zinc dust, or small pieces of zinc, are then added, when the remainder of the copper, together with the tin, is thrown down in the form of a dark gray, spongy couple, which is washed by decantation. About 3 grms. are used for each litre of the diluted acid. The mixture is gradually heated, a strong reaction taking place at about 70° C., and kept at a boiling temperature for 15 minutes. The acid is then distilled, a little of the couple and a small piece of copper gauze being placed in the distillation flask.

The couple should be gray in colour; if it is nearly black too much copper is present. The residue in the distillation flask serves conveniently for the preparation of fresh copper-tin couple.—W. P. S.

Magnesium; Alloys of —— with cadmium, zinc, bismuth and antimony. G. Grube. Z. anorg. Chem., 1906, **49**, 72—92.

THE author has investigated the alloys of magnesium with cadmium, zinc, bismuth and antimony, and has proved the existence of the compounds, CdMg, Zn_2Mg, Bi_2Mg_3 and Sb_2Mg_3. No evidence could be obtained of the existence of the compounds, $CdMg_4$, $CdMg_{30}$ and $ZnMg_4$, mentioned by Boudouard (this J., 1902, 976; 1904, 868). The compounds, MgCd, Bi_2Mg_3 and Sb_2Mg_3, decompose water, and are less resistant to the influence of moist air than either of their components. The compound, Zn_2Mg, on the other hand, is less acted upon by moist air than either zinc or magnesium, resembling in this respect the compound of aluminium and magnesium, Al_3Mg_4. —A. S.

Aluminium-bronze industry; Cause and prevention of explosions in the ——. M. M. Richter. Chem.-Zeit., 1906, **30**, 324—326.

THE author traced a number of explosions to electric sparks proceeding from excitation of the brushes in elevating, polishing and similar machines, by which sparks the ignition of mixtures of aluminium dust and air was determined. He recommends therefore that:—(1) The brushes in machinery employing them (Steigmühlen, &c.) should be replaced by brushes of aluminium wire; and (2) those in polishing machines should have their fibres soaked in weak sulphuric acid, should contain a few fibres of elastic wire, and should be bound with copper wire and electrically connected with the metal work of the machinery.—J. T. D.

Nickel and antimony; Alloys of ——. K. Lossew. Z. anorg. Chem., 1906, **49**, 58—71.

THE m. pt. curve of antimony-nickel alloys has two distinct maxima at 1158° C. and 1170° C. respectively, corresponding to the compounds, NiSb and Ni_5Sb_2, and three minima corresponding to eutectic mixtures. Starting from the solidifying point of antimony at 630° C., the curve descends to the first eutectic point at 611° C. (between 2 and 3 per cent. of nickel) and then rises to the first maximum at 1158° C. (32·83 per cent. of nickel). In the alloys, containing from 3 to 32·83 per cent. of nickel, three constituents can be recognised micrographically, *viz.*, the eutectic, yellow crystals of the compound, NiSb, and another compound, probably Ni_3Sb_5, forming a white ring round the yellow crystals. From 32·83 to 40 per cent. of nickel a series of mixed crystals separates, and from 40 to 47·60 per cent. of nickel the alloys consist of the mixed crystals and a second eutectic. From 47·60 to 54·97 per cent. of nickel, rounded crystals of the compound, Ni_5Sb_2 (m. pt. 1170° C.), separate from the eutectic, whilst from 54·97 to 57·0 the alloys consist of a second series of mixed crystals. From 57·0 onwards the alloys at the solidifying point consist of an eutectic (m. pt. 1100° C., 66 per cent. of nickel), together with mixed crystals of different composition, according to whether the alloy contains more or less than 66 per cent. of nickel. In these alloys a reaction between the two kinds of mixed

crystals takes place at 677° C., with formation of the compound, Ni_4Sb. The reaction is reversible; if a slowly-cooled alloy containing 65·2 per cent. of nickel and consisting almost entirely of the compound, Ni_4Sb, be heated at 700° C. and quenched in water, it is then found to consist of a mixture of the two kinds of mixed crystals previously mentioned, whilst if it be allowed to cool in the air, it is found to consist mainly of the eutectic mixture of the two kinds of mixed crystals, together with small quantities of the compound, Ni_4Sb.—A. S.

Queensland; Mineral production of ——. Bd. of Trade J., April 19, 1906.

THE following statement shows the quantities of the different minerals, other than gold, precious stones and coal, produced in Queensland in 1905, and their respective values as compared with 1904:—

——	1904.		1905.	
	Quantity.	Value.	Quantity.	Value.
	Tons.	£	Tons.	£
Copper	4,325	255,866	7,041	485,093
Lode tin	2,393	151,984	2,307	161,580
Alluvial tin	1,467	112,254	1,447	125,739
Lead	1,951	23,339	2,151	29,075
Manganese	780	3,119	1,361	5,444
Wolfram	1,123	118,974	1,314	92,740
Molybdenite	21	2,673	63	8,463
Bismuth	4	1,128	9	3,048
Bismuth and wolfram	4	369	20	1,960
Scheelite	3	300	5	341
Ironstone	4,753	1,705	4,066	3,111
Limestone	16,215	9,304	21,227	14,554
Antimony	—	—	23	169
	oz.		oz.	
Silver	597,251	64,952	535,622	61,631
Total value	—	745,967	—	992,948

The figures for coal and precious stones are not yet complete; in 1904 these products were valued at £177,000. The gold yield last year amounted to 578,364 fine oz., against 639,151 oz. in 1904, but the decrease will be lessened when the return is completed by the addition of the full returns from metallurgical works. [T.R.]

Norway; Mining industry in ——. For. Off. Ann. Series, No. 3555.

Copper.—The output of the Sulitjelma mine rose in 1905 to about 87,000 tons. A new smelting furnace, invented by the manager, is stated to reduce the expense of smelting to one-half or even one-third of the former cost. The system will also be used in the Alten copper works in Finmarken. The Bosmo mine in Nordland produced the same quantity as in former years, about 25,000 tons of pyrites. The Röros copper works have been worked under somewhat more favourable conditions than of late; about 30,000 tons were produced. Of other and more important copper mines, the Kjöli, Killingdal and Mandfield may be mentioned, the last-named being expected to produce before long about 60,000 tons annually. It is stated that there are very extensive deposits at Röstvangen that are at present not available on account of difficulties of transport. The exportation of pyrites from Norway has increased considerably within the last year or two, and the Norwegian cellulose factories now also absorb a large amount.

Silver.—The output of the Kongsberg silver mines (16,640 lb.) during the past financial year was rather less than in the preceding year, but the price of silver was higher.

Iron.—Of iron ore, 44,000 tons were exported from the Fehn mines, 14,000 tons from Meló, and smaller amounts from other mines. If the Dunderland works prove to be remunerative, a large number of other mines containing similar ore may be expected to be opened up. In South Varanger, work on a large scale is to be started before long.

Molybdenite.—The Knaben molybdenite mine produced in 1905 about 29 tons of high-class ore,

Calcium carbide.—Calcium carbide is manufactured at Hafslund, Borregaard, Notodden and Meraker; the exports rose from 5258 tons in 1904 to nearly 9000 tons in 1905. [T.R.]

ENGLISH PATENTS.

Ores; Apparatus for treating ——. W. A. Hendryx, Los Angeles, U.S.A. Eng. Pat. 1928, Jan. 31, 1905.

SEE U.S. Pat. 785,214 of 1905; this J., 1905, 447.—T.F.B.

Filter presses for separating the heavier or coarser from the lighter or finer components found in the tailings of ores or other material. W. P. Thompson, London. From C. W. Merrill, Lead, U.S.A. Eng. Pat. 5970, March 21, 1905.

SEE U.S. Pat. 798,200 of 1905; this J., 1905, 1004.—T.F.B.

Deposits or tailings from ore crushing; Method of and apparatus for separating, selecting, concentrating and securing precious matters from ——. J. Hutchings, London. Eng. Pats. 6556B and 6556C, March 28, 1905.

THE ore particles are first classified or assorted according to size by means of differently meshed sieves within a revolving screen or cylinder, and are then treated with water in a pan divided into compartments, the pan being at the same time given a swinging or oscillating movement by means of which the concentrates are separated from light and valueless matter. The concentrates are then further treated in a protective safe apparatus with locked cover by means of a magnetic separator, which separates iron pyrites, &c., from the gold, leaving the latter in a partially cleansed condition. Apparatus is also provided for forcing the fine float gold, by means of a copper wire brush, into a mercury trough for the purposes of amalgamation. The protective safe apparatus forms the subject of the separate patent 6556C.—A. G. L.

UNITED STATES PATENTS.

Lead sulphide; Process of smelting ——. A. G. Betts, Troy, N.Y. U.S. Pat. 816,772, April 3, 1906.

LEAD sulphide is smelted with substances containing iron and sodium, whereby metallic lead and an iron-sodium matte are produced. The metallic lead is separated, together with some slag, and the sulphur is eliminated from the fused matte by an air-blast, the oxidised residue being subsequently used for smelting lead ore.—A. S.

Lead sulphide; Smelting ——. A. G. Betts, Troy, N.Y. U.S. Pat. 816,773, April 3, 1906.

LEAD sulphide ore is smelted with compounds of iron and sodium, carbon, and basic compounds of iron or sodium, or both, to produce metallic lead, an iron-sodium matte, and a slag containing less than 2 per cent. of ferrous oxide. According to one claim, the charge is first smelted so as to produce a slag containing more than

2 but less than 5 per cent. of ferrous oxide, and this slag is then treated at a smelting temperature with sulphur compounds in order to form further quantities of iron-sodium matte and a slag containing less than 2 per cent. of ferrous oxide.—A. S.

Gas-producing and consuming apparatus [Zinc-distilling furnace]. C. Ellis, Assignor to Combustion Utilities Co., New York. U.S. Pat. 816,973, April 3, 1906.

In an apparatus for reducing and distilling zinc or other metals, a gas-fired furnace, provided with metal-distilling retorts of refractory material, is combined with a gas-producer supplying gas to the furnace. The heat of the waste products of combustion from the furnace is transferred to the entering gas and air by means of regenerative devices. A portion of the products of combustion is abstracted by a fan and delivered through a conduit to the producer. Means for supplying air to this conduit and for regulating the proportion of air and of products of combustion are provided. The furnace may be fed with dry producer gas, substantially free from hydrogen and steam.—R. L.

Furnace; Metallurgical ——. G. H. Benjamin, New York, N.Y. U.S. Pat. 817,099, April 3, 1906.

The furnace consists of a number of receptacles together with "regenerative chambers." The receptacles have valved feed-inlets and outlets and are mounted end to end in such a manner that they can be rotated independently. Means are provided for heating the receptacles and also flues and valves, by means of which communication can be opened or closed between one or more of the receptacles and the "regenerative chambers."—A. S.

Cupola. A. Baillot, Haybes, France. U.S. Pat. 817,412, April 10, 1906.

See Fr. Pat. 349,036 of 1904; this J., 1905, 624.—T.F.B.

Ore separator. G. Moore, London. U.S. Pat. 817,655, April 10, 1906.

See Eng. Pat. 25,110 of 1904; this J., 1906, 319.—T.F.B.

French Patents.

Steel; Process of making ——. V. Defays. Fr. Pat. 360,033, Dec. 2, 1905. Under. Int. Conv., Dec. 12, 1904.

See Eng. Pat. 28,570 of 1904; this J., 1906, 125.—T.F.B.

Furnaces with movable tuyères; Process for detaching the deposits which form at the point of contact of the combustible with the walls of rotary ——. Fellner und Ziegler. Fr. Pat. 360,170, Dec. 7, 1905. Under Int. Conv., March 8, 1905.

See U.S. Pat. 801,144 of 1905; this J., 1905, 1113.—T.F.B.

Metals; Extraction of —— from minerals containing them. J. D. Wolf. Fr. Pat. 360,247, Dec. 8, 1905.

See Eng. Pat. 17,407 of 1904; this J., 1905, 1309.—T. F. B.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 381.)

(A.)—ELECTRO-CHEMISTRY.

Sulphuric acid; Electric conductivity of dilute solutions of ——. W. C. D. Whetham. Z. physik. Chem., 1906, **55**, 200—206.

The electric conductivity of aqueous solutions of acids and alkalis increases with the dilution to a maximum and then rapidly falls again. Goodwin and Haskell (Phys. Review, 1904, **19**, 369) have stated that this decrease of conductivity is due to the contamination of the water by traces of carbonic acid. The author, from experiments with sulphuric acid dissolved in specially purified distilled water, with and without the addition of a trace of potassium chloride and of carbon dioxide respectively, find that whilst the presence of carbonic acid is probably one of the causes of the decrease in conductivity of extremely dilute solutions of acid, other causes as yet unknown must also come into play.—A. S.

Electrolysis; Analytical separation of metals by ——. A. Hollard. XXIII., page 445.

English Patents.

Catalytic combinations; Substances for effecting —— *in electrolytic electricity meters.* C. O. Bastian and G. Calvert, both of London. Eng. Pat. 6448, March 27, 1905.

A mixture of platinum or platinum black and palladium or palladium black is used as a catalytic agent for bringing about the re-formation of water from electrolytic gas in an electrolytic electricity meter. The mixture is painted on or otherwise attached to a suitable medium, or it may be mixed with glass wool and enclosed in a porous container.—B. N.

Accumulators or secondary batteries; Plates for ——. F. J. Gerard and L. Fiedler, both of London. Eng. Pat. 6786, March 30, 1905.

Plates for accumulators are made by mixing lead oxide into the form of a paste with the following solution:—350 parts of lecithin, 10 parts of lead acetate or nitrate, 10 parts of mercury sulphate and 1000 parts by weight of distilled water, the paste being afterwards forced into the interstices of grids or frames.—B. N.

Electrode; Storage battery ——. T. A. Edison, Orange, N.J., U.S.A. Eng. Pat. 1925, Jan. 25, 1906. Under Int. Conv., March 30, 1905.

The active mass of nickel hydroxide, used for electrodes of storage batteries with an alkaline electrolyte, is intimately mixed with conducting flakes, scales, films or foil of metallic cobalt, or an alloy of cobalt and nickel.
—B. N.

Electrode mass for storage batteries and process of forming the same. T. A. Edison, Orange, N.J., U.S.A. Eng. Pat. 1927, Jan. 25, 1906. Under Int. Conv., March 30, 1905.

The active mass for storage batteries employing alkaline electrolytes is composed of relatively large particles of an electrolytically active material, such as nickel hydroxide, the particles being coated with scales, flakes or foil of conducting material, such as graphite, cobalt, nickel, or cobalt-nickel alloy. The mass is first intimately associated with a sticky material, such as molasses, in order to thoroughly cover the surface of the active particles, and the conducting flakes are then thoroughly mixed with the mass until the particles of the latter are practically entirely covered with the flakes. The mass is then compressed in the pockets or receptacles for containing it, so that the flakes present a network of conductors extending in all directions through the mass. The sticky material is finally dissolved out of the mass by water rendered slightly alkaline.—B. N.

Ozonising apparatus; Impts. in [Electrical] ——. G. E. Gaiffe, Paris. Eng. Pat. 22,103, Oct. 30, 1905. Under Int. Conv., May 13, 1905.

This invention relates to an apparatus for the production of ozone, and consists of an ozoniser connected in series with a "capacity" of known value, the ozoniser being unprovided with a dielectric and fed by currents of high frequency.—B. N.

Peat and the like; Extracting moisture from —— *[electrically].* W. Simm. Eng. Pat. 4792, March 8, 1905. II., page 420.

UNITED STATES PATENTS.

Refractory material for electric insulation and other purposes; and process of producing same. D. M. Steward. U.S. Pats. 816,270 and 816,271, March 27, 1906. IX., page 428.

Electric furnace. A. G. Betts, Troy, N.Y. U.S. Pat. 816,554. April 3, 1906.

THE furnace consists of a furnace-chamber, the hearth of which contains a bath of a liquid conductor; a channel, both ends of which lead into this chamber, and which also contains the liquid conductor; and two electrodes, one connected with the liquid in the chamber, the other with the liquid in the channel. At a certain part of the channel, a magnetic field is created by an electro-magnet, and at the same part, a cross-channel, containing a conductor and intersecting the main channel, is provided. By causing an alternating current to pass through the cross-channel and to alternate synchronously with the current in the main channel, the liquid conductor is made to circulate from the hearth through the channel and back to the hearth again.—A. G. L.

Ammonia; Process of producing —— *[electrolytically].* J. A. Lyons and E. C. Broadwell. U.S. Pat. 816,928, April 3, 1906. VII., page 427.

FRENCH PATENT.

Ozonising atmospheric air; Apparatus for ——. Ozonair, Ltd. Fr. Pat. 360,227, Dec. 8, 1905. Under Int. Conv., Aug. 11, 1905.

SEE Eng. Pat. 16,392 of 1905; this J., 1905, 1115.—T. F. B.

(*B.*)—ELECTRO-METALLURGY.

ENGLISH PATENTS.

Furnaces; Electric ——. A. Reynolds, London. Eng. Pat. 7004, April 3, 1905.

THE heating resistance comprises a material, such as carbon, which is electrically conducting at furnace temperatures, and thus is contained within a casing of electrically insulating but thermally conducting material, such as "siloxicon," this substance being chemically inert to the molten furnace charge, the furnace atmosphere and the resistive material at all furnace temperatures. In some cases it is advantageous to surround the "siloxicon" with an outer casing of magnesite or basic or neutral aluminium silicate, free from or low in alkali, the magnesite being used with basic, and the silicate with acid slags. Different forms of furnaces are described in which the charge of the furnace is part of the electric circuit, the current passing from the resistive material through a conducting button, forming the bottom of the insulating casing, to the charge and thence to the crucible, which is attached to the other terminal; and also forms of furnaces in which the charge does not act as part of the electric circuit, the current being passed through several heating resistances connected in parallel, these being in electrical contact with a conducting ring or button in the base of the crucible and attached to the other terminal of the current.—B. N.

Copper; Process for the electrolytic production of ——. J. A. W. Borchers and F. E. Günther, Aachen, and P. R. Franke, Eisleben, Germany. Eng. Pat. 19,638, Sept. 28, 1905. Under Int. Conv., Oct. 4, 1904.

SEE Ger. Pat. 160,046 of 1904; this J., 1905, 897.—T. F. B.

UNITED STATES PATENT.

Lead ores; Process of smelting ——. W. Valentine and A. G. Betts, Troy, N.Y. U.S. Pat. 816,764, April 3, 1906.

LEAD-SULPHIDE ores with the accompanying gangue are fused so as to form a matte and a slag, and the lead is separated electrolytically from the matte, by bringing the latter into contact with a cathode in an electrolyte of fused sodium chloride containing sodium sulphide.—A. S.

FRENCH PATENT.

Metals; [Electrolytic] Process for separating ——. N. V. Hybinette. Fr. Pat. 360,101, Dec. 5, 1905.

SEE U.S. Pat. 805,969 of 1905; this J., 1906, 29.—T. F. B.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 383.)

Moringa oleifera; Seeds of ——. E. Drabble. Quart. J. Inst. Commercial Research in the Tropics, Liverpool Univ., 1906, **1**, 66—67.

THIS tree, indigenous to India, Arabia and Syria, has been introduced into several tropical countries for the purpose of obtaining the seed oil (Ben oil). It grows well in any soil, and can resist drought. The decorticated seeds yield about 38 per cent. of a pale yellow or nearly colourless oil, of which about 40 per cent. is solid fat. They contain about 35 per cent. of proteids, which would render them of value for seed-cake after expression of the oil (see Lewkowitsch, this J., 1904, 25).—C. A. M.

Butyrospermum Parkii; Seeds of —— *[Shea Butter seeds].* E. Drabble. Quart. J. Inst. Commercial Research in the Tropics, Liverpool Univ., 1906, **1**, 67.

Two different samples of these seeds were examined. One resembled the West African Shea butter seeds and yielded 51·5 per cent. of fat, with iodine value 59·9 and saponification value 179, whilst a specimen of the West African seeds gave 53·5 per cent. of fat, with iodine value 56·9 and saponification value 183. The other seeds, sent under the name of "Kariti nuts," were larger and paler in colour than the West African seeds, and yielded 34 per cent. of fat, with iodine value 65·8, and saponification value 179. The fat could be used for the same purposes as ordinary Shea butter.—C. A. M.

Mucuna oil; Examination of ——. W. P. H. Van den Driessen Mareeuw. Pharm. Weekblad, 1906, **43**, 202—209. Chem. Centr., 1906, **1**, 1176—1177.

THE seeds of the leguminous plant, *Mucuna capitata*, Dc., known as "kratok" beans and in the Dutch Indies as "Bengoek," yield to petroleum ether 2·08 per cent. of a yellow fatty oil yielding the following numbers:—Oil from fresh seeds: Sp. gr., 0·865; solidifying point, 3·5° C.; m. pt., 16° C.; Zeiss butyro-refractometer reading at 25° C., 66·2 scale divisions; acid value, 6·72; saponification value, 178·22; iodine value, 103·95; Reichert-Meissl value, 0·77; m. pt. of mixed fatty acids (oleic (?), palmitic and stearic acids), 37° C.; saponification value of fatty acids, 195·6; iodine value of fatty acids, 112·9; m. pt. of acetylated fatty acids, 24° C.; acetyl-acid value of fatty acids, 145·7; acetyl-saponification value of fatty acids, 260·95. Oil from seeds two months old: Sp. gr., 0·8700; acid value, 32·75; saponification value, 184·76; iodine value, 98·6; saponification value of fatty acids, 187·7; iodine value of fatty acids, 107·53.—A. S.

Wax of Rhaphia ruffia. H. Jumelle. L'Union Pharm., 1906, **47**, 59—61.

THE leaves of *Rhaphia ruffia*, stripped of their upper epidermis to furnish the commercial raffia fibre, also yield a wax. The segments of the stripped leaves are dried, and then beaten in a fine cloth, by which means a white powder is obtained. This is sifted and thrown into boiling water, when the wax melts and is separated. This wax is dull, dry and but slightly greasy to the touch; it is brittle with a dull, smooth fracture, and is readily reduced to powder in a mortar. It resembles carnauba wax in general appearance. It is only sparingly soluble in chloroform, ether, petroleum spirit, cold alcohol and most other solvents, but is readily dissolved in boiling alcohol, from which it precipitates on cooling; the precipitate, thrown on a filter, forms an unctuous mass, becoming granular and friable on drying. Its sp. gr. is 0·950; m. pt., 82° C. The melted liquid gives a brownish

wax on cooling; if melted several times it becomes deep chestnut-brown, and has a lustrous surface and a sharp fracture. It melts in the flame without burning. The unmelted part remains hard, and the fused portion does not mould well in the fingers and is not sticky.—J. O. B.

ENGLISH PATENT.

Soap; Process for converting insoluble —— into soluble soda soap or potash soap. P. Krebitz, Munich, Germany. Eng. Pat. 4092A, Feb. 27, 1905.

INSOLUBLE soap, obtained as described in Eng. Pat. 4092 of 1905 (this J., 1906, 188), is treated with potassium or sodium carbonate in excess (2 to 6 per cent.) of the theoretical amount, which is stated to prevent soap being mechanically carried down by the subsiding calcium carbonate. The conversion is promoted by the addition of salt. The process may be carried out either by adding the insoluble soap gradually to a boiling solution of sodium carbonate, or by pouring the hot carbonate solution over the soap and boiling the mixture.—C. A. M.

FRENCH PATENT.

Cooling apparatus for soap or other material. A. E. Boardman. Fr. Pat. 360,163, Dec. 7, 1905. Under Int. Conv., Dec. 9, 1904.

SEE Eng. Pat. 24,023 of 1904; this J., 1905, 1074.—T.F.B.

Silicon monoxide [Pigment, &c.]; Manufacture of ——. H. N. Potter, New York. Eng. Pat. 26,788, Dec. 22, 1905. Under Int. Conv., Dec. 30, 1904.

To effect a partial reduction of silica to silicon monoxide, a mixture of the former with the necessary proportion of carbon is heated electrically in a closed furnace of either the resistance or arc type, provision being made for withdrawing the carbon monoxide gas as it is formed. "This bursting out of the carbon monoxide gas from the point of reaction carries the silicon monoxide with it, but whether in a solid, liquid or gaseous state the inventor is not able to state;" in any case, a large portion of it, at least, "is carried out of the region of reaction." Provision is made for trapping the silicon monoxide, as it escapes, in collection chambers. The silicon monoxide thus produced is an extremely fine powder, which can be used, alone or in combination, as a pigment; or it may be pressed into bricks, with or without addition of alumina, magnesia or the like, to form abrasion wheels. A vitreous form of the silicon monoxide also sometimes occurs, which is distinguished from crystalline silicon by being a non-conductor of electricity.—E. S.

Paint; An improved ——. H. N. Potter, New York. Eng. Pat. 1279, Jan. 17, 1906. Under Int. Conv., Jan. 25, 1905.

SILICON monoxide, in powder, is mixed dry with another pigment, ground and incorporated with oil or other paint vehicle; or the order in which the ingredients are mixed may be reversed (see preceding abstract).—C. S.

UNITED STATES PATENT.

Paint and varnish remover; Non-inflammable ——. C. Ellis, Assignor to Chadeloid Chemical Co., New York. U.S. Pat. 817,141, April 3, 1906.

THE paint or varnish remover consists of a waxy body mixed with a non-inflammable volatile solvent, together with other volatile solvents of less vapour tension, so as to give a predominant evaporative tendency to the former solvent, the proportion of wax not to exceed 8 per cent. A mixture of 2 parts of wax, 15 parts of carbon tetrachloride, 10 parts of grain alcohol and 1 part of amyl acetate is specified.—J. F. B.

(*B.*)—RESINS, VARNISHES.

FRENCH PATENT.

Linoleum, oilcloth and similar material; Machine for printing designs on ——. H. C. Shaw. Fr. Pat. 360,309, Dec. 11, 1905. Under Int. Conv., Dec. 12, 1904.

SEE Eng. Pat. 27,037 of 1904; this J., 1905, 1180.—T. F.B.

(*C.*)—INDIA-RUBBER, Etc.

Rubber from Castilloa elastica. Quart. J. Inst. Commercial Research in Tropics, Liverpool Univ., 1906, 1, 101—119.

Cultivation of Castilloa.—The yield of latex is proportional to the size of a tree rather than to its age, and is dependent on the soundness of the roots. Rapid growth is favoured by large surface of leaf. As to spacing, it is recommended to set out stakes in 15—20 ft. squares and plant a circle of eight or ten trees around each. The weaklings having been cut down, there will be three or four good trees in each group when, after about six years, they are ripe for tapping. A variety of insect pests attack the trees, the most important being a borer, probably the long-horn beetle, and a small bark beetle. Both these are dealt with by means of carbon bisulphide or gasoline.

Tapping for latex.—The arrangement of cuts generally adopted, *viz.*, one at the base, one 5 ft. above the ground, and one intermediate, is uneconomical; four cuts, the highest being 6 ft. above the ground, are recommended. Three methods of tapping are in use, *viz.*, (1) making crude cuts with the machete; (2) making a ring of incisions with a chisel about 1 in. broad; and (3) cutting out V-shaped pieces of bark, stretching about half-way round, with a special tool. Cuts made right into the wood do not heal completely; but, on the other hand, the same applies to cuts which do not reach the cambium. A larger yield of latex is obtained from cuts right into the cambium than from cuts almost into it. In the author's opinion, the narrower the cuts, the better. The latex flows best during the rainy season, and in the early morning. Cups for collecting latex should not be conical, since these are difficult to wash out, and they are better fixed to the tree by pushing in the sharp edge than by means of pins; those now in use contain about 60 c.c., and are, if anything, too small. The first flow of latex—about a cupful—is followed by a slow ooze of less watery latex, which ceases in 15 minutes or so, and is removed with a spoon or with the fingers.

Manipulation of latex.—The collected latex is freed from bark and mud by washing. On shaking up latex with water and allowing to stand, solid impurities go to the bottom, the water is blackened, and the latex rises to the top. This separation is greatly delayed by the presence of mud. Repeated washing renders the rubber whiter and less sticky, but adds nothing to its strength or elasticity, whilst it introduces the risk (1) of the latex refusing to separate out, and (2) of premature coagulation of the rubber.

Coagulation and drying of rubber.—A useful method of preparing rubber from latex is to run the latter upon sheets of blotting paper and allow it to dry. Each sheet of paper serves to coagulate ten or more sheets of rubber. The author suggests, as an improvement on this process, pressure between two porous tiles. Coagulation may also be effected by boiling the latex. The resulting

rubber is apt to be uneven and contain an excessive quantity of moisture. Or, again, chemicals, *e.g.*, alcohol, sulphonaphthol, acids, &c., may be added to the latex. Alcohol is an excellent, if costly, coagulant; sulphonaphthol is certain in its action, but makes a weak rubber; sulphuric acid, lime-juice, sodium carbonate, and calcium chloride are somewhat uncertain and tend to produce weak rubbers. The coagulated rubber should be dried by artificial heat until completely translucent.

Miscellaneous observations.—Latex can be prevented from coagulating for a long time by the addition of ammonia, which imparts a yellow colour to it. The "black water" obtained in the washing process is rendered brownish-red by caustic soda and deep black by ammonia, whilst acids gradually bring down a yellow precipitate. Sugar bleaches the "black water."

The yield of rubber from good six-year-old *Castilloas* may be estimated at half-a-pound per tree annually. Young trees and young parts of old trees give rubbers containing notable proportions of resin. As compared with *Castilloa*, *Hevea* yields latex less freely, but responds better to repeated tapping. Its latex is cleaner, but coagulates much more easily; the globules are so fine that they cannot be coagulated by the blotting-paper method. *Castilloa* rubber, in the author's experience, has greater strength and elasticity than *Hevea* rubber.

—W. A. C.

India-rubber; Analyses of some different brands of ——. D. Spence. Quart. J. Inst. Commercial Research in the Tropics, Liverpool Univ., 1906, **1**, 75—77.

The rubber was finely divided, dried over calcium chloride at 55° C. until constant in weight, and extracted successively with acetone and chloroform, the latter extraction giving the amount of caoutchouc. The samples of commercial rubber had not been treated in any way.

Sample.	Duration of cure.	Breaking strain.	Elongation.
	min.	kilos.	cms.
1	1	14	3·6
2	2	15	3·9
3	3	15·2	3·0
4	4	15·62	6·5
5	5	16·25	5·0
6	6	12·0	3·8
7	7	15·0	3·7
8	8	15·25	3·8
9	9	16·5	7·4
10	10	18·5	6·2

The unvulcanised strip broke at 7·5 kilos., and had an elongation of 2·2 cm. Even the strip cured only one minute was therefore much stronger and more elastic.

Rubber exports from Manáos and Pará. Bd. of Trade J., April 19, 1906.

The following are particulars of the exports of Seringa rubber from the Ports of Manáos and Pará during the years 1904 and 1905:—

Seringa Rubber.	1904. Quantity.	1904. Value.	1905. Quantity.	1905. Value.
	Kilos.	£	Kilos.	£
Fine	14,072,000	6,645,000	16,473,000	8,460,000
Medium ..	2,471,000	988,000	2,756,000	1,269,000
Sernamby ..	7,430,000	1,910,000	7,510,000	2,108,000
Caucho	3,632,000	943,000	4,726,000	1,237,000
Total	28,505,000	10,486,000	31,475,000	13,234,000

The above figures are inclusive of rubber shipped from Itacoatiara, but exclusive of rubber from neighbouring countries shipped from the ports of Amazonas and Pará.

The resins from Nos. 1, 5 and 9 were soft and glue-like or oily, whilst those from the other samples were more or less hard.—C. A. M.

Rubber; Influence of duration of cold vulcanisation upon tensile strength and elasticity of Pará ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 678—679.

Strips of Pará rubber, 5 cm. by 3 cm. by 7 mm., were carefully dried and vulcanised by immersion in a solution of sulphur chloride in 80 times its own weight of carbon bisulphide. The vulcanised strips were immediately washed with a weak solution of sodium carbonate, and then with warm water, and dried for two days in a desiccator over calcium chloride. The breaking strain and elongation of the test pieces were then determined across a section 3 cm. by 7 mm., a strip 1 cm. long between the clips of the machine being used. The variation of strength and elongation with the length of time during which the sample was immersed in the vulcanising liquor is shown by the following figures, which indicate a maximum of strength at five minutes' cure, followed by a minimum at six minutes, and maxima of elongation at three and nine minutes' cure, with a minimum at seven minutes:—

French Patents.

[*Rubber substitute*] *Material; New —— unattacked by acids, for covering metallic and other casings.* P. Lacollonge. Fr. Pat. 360,287, Feb. 18, 1905.

Stearine pitch (90 to 80 per cent.) is melted together with ceresin or ozokerite (10 to 20 per cent.) at a temperature below 110° C., after which powdered picric acid (2 to 4 per cent. on the pitch) is stirred into the mass. The temperature is then raised to 125° C., with constant stirring, and the heating continued for some time; the temperature should never rise beyond 130° C. during this time. The mass is then mixed with various powders or fibres and the heating continued at from 130° to 140° C., as in the vulcanisation of rubber. The mixture obtained is moulded into sheets or other shapes as desired.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 384.)

Tannin-containing substances; Examination of some ——. J. Sack. Inspectie van den Landbouw in West Indie. Bull., No. 5, 1—8. Chem. Centr., 1906, **1**, 1106—1107.

Mangrove (*Rhizophora Mangle*). The older plants contain more tannin than the younger ones. The dry substance of the bast contains up to 24·5 per cent. of tannin. The bast was finely ground, repeatedly extracted with cold water, and the filtered, deep red solution treated with lead acetate till a white precipitate began to be formed. After again filtering, a further quantity of lead acetate was added, and the white precipitate thus obtained was suspended in alcohol and freed from lead by means of hydrogen sulphide. The filtrate from the lead precipitate was evaporated with exclusion of air, and was found to contain the reddish-brown tannin, $C_{24}H_{26}O_{12}$, easily soluble in water and alcohol, but insoluble in ether. On heating with sodium acetate and acetic anhydride, the tannin yielded a mono acetate, $C_{24}H_{23}O_{11}.C_2H_3O$, m. pt. 205° C., the tannin probably first forming the anhydride, $C_{24}H_{24}O_{11}$, which then reacted with the acetic anhydride. On treatment with water containing hydrochloric acid, the tannin yielded a "tannin-red," according to the equation, $2C_{24}H_{26}O_{12} - 3H_2O = C_{48}H_{46}O_{21}$. *Mambarklak* (*Lecythisamara Aubl.*) from Surinam. The bast of this plant yields only a few per cent. of tannin, but contains also a white substance possessing the characters of a saponin. *Oemabarklak* (*Bigonia inaequalis*, D.C.) The bast contains 21 per cent. of matter soluble in water, 14 per cent. of tannin, and also saponins. The bast of *Krappa* (*Carapa guyanensis*) contains 11 per cent. of soluble substances and 5 per cent. of tannin. The bast of *Cassia floridu*, *Vahl* contains 54·8 per cent. of water, 3·4 per cent. of ash, 6·6 per cent. of matter soluble in water, and 2·5 per cent. of tannin. The dried husks contain 10 per cent. of tannin, and the seeds, 19·2 per cent. of water, 5·4 per cent. of ash and 44·7 per cent. of oil.—A. S.

English Patent.

Tanning of hides and skins. J. Rivière, P. Verroul and A. Bouvier, Lyons, France. Eng. Pat. 16,312, Aug. 10, 1905.

See Fr. Pat. 350,026 of 1904; this J., 1905, 1023.—T. F. B.

(*Continued from page* 384.)

Phosphate exports from Christmas Island. Bd. of Trade J., April 26, 1906.

The following particulars, taken from the Annual Report on Christmas Island for 1905, show the quantity of phosphates shipped from these Islands during the five last years:—1901, 42,125 tons; 1902, 61,179 tons; 1903, 70,096 tons; 1904, 71,757 tons; 1905, 97,952 tons. [T.R.]

United States Patent.

Nitrogen; Process of preparing, growing and distributing organisms which fix or gather atmospheric ——. G. H. Earp-Thomas, Wellington, New Zealand. U.S. Pat. 816,850, April 3, 1906.

A nodule from a leguminous plant is thoroughly cleansed and sterilised; it is then fractured under aseptic conditions, and the bacteria thus obtained are mixed with sterilised water. A portion of the milky fluid is transferred to a culture medium which is substantially free from nitrogen, the culture is developed and re-inoculated in distributing packages also containing a non-nitrogenous medium. When the bacteria have developed, the packages are sealed up. A suitable medium for these bacteria consists of 14 grms. of wood ashes, 26 grms. of shredded agar, and 35 grms. of maltose in 2210 c.c. of water.—J. F. B.

XVI.—SUGAR, STARCH, GUM, Etc.

(*Continued from page* 385.)

Beetroots, Determination of sugar in Italian ——. E. Viviani and D. Galeati. Bull. Assoc. Chim. Sucr. Dist., 1906, **23**, 1016—1020.

On many sides there is an inclination to adopt Pellet's cold aqueous digestion process for the determination of sugar in beetroots in preference to the alcoholic process. Pellet's process consists in digesting the normal weight of rasped pulp with cold water and diluting to a total volume of 201·35 c.c. after the addition of 5—7 c.c. of basic lead acetate solution of 30° B., exhausting the air, if necessary under vacuum, filtering, and adding two or three drops of acetic acid to the filtrate. The authors have examined this process comparatively with the alcoholic processes and have obtained absolutely concordant results, even when the ratios of sugar to non-sugar were very different. They find that the objection urged against aqueous digestion, *viz.*, that optically active non-sugar components are present in the filtrate, is not valid. These substances are eliminated by the basic lead acetate as efficiently as by alcoholic digestion. In employing the "rapid" processes of Le Docte and Kruger (see Pellet, this J., 1896, 746) for Italian beetroots, the authors find a constant error of 0·20—0·35 per cent. of sugar too low. Processes of this sort are based on the assumption that the average proportion of juice in beetroots is constant; but Italian beets in the fresh state appear to contain a somewhat excessive proportion of juice. In order to obtain a total volume of liquid of 100 c.c. in these processes with Italian beets, it is necessary to add 70·32 c.c. of basic lead acetate solution to 26·048 grms. of pulp instead of 78·14 c.c. as prescribed by Krüger.—J. F. B.

Sugar cane products; Fermentation of ——. C. A. Browne, jun. J. Amer. Chem. Soc., 1906, **28**, 453—469.

The juice of the green tops of the sugar cane contains invertase, which brings about a gradual inversion of the sucrose in the cane after it is cut, unless the tops be removed at the same time. The sugar cane also contains oxydases and catalases, sometimes called reductases. If an oxidisable substance, such as quinol (hydroquinone) be added to raw cane juice, a rapid darkening, due to the oxidation of the quinol by the enzyme, takes place with absorption of oxygen; the oxidised product possesses antiseptic properties capable of preserving the juice for weeks. In the cane, the tannins play the same part as the quinol; fresh juice from raw cane darkens rapidly, and the number of bacteria per c.c. either decreases or only increases slightly during the first few hours, whereas in the juice expressed from steamed canes the number of bacteria increases rapidly from the first. When a living cane is injured, the surface of the wound gradually darkens owing to the above action, and the wound remains free from signs of fermentation; but with frost-bitten or sterilised canes, the surface of the injury is soon attacked by moulds and bacteria. In the living cane the activity of the reductases

vents the diffusion of the toxic oxidation products, borated for protective purposes at the injured surface, m diffusing into the cane. The most common fer- ntation of raw cane juice in Louisiana is the viscous, cilaginous or mannitic fermentation, produced by *uconostoc*. This is an anaërobic fermentation, and the ce is rapidly bleached. The viscous product a gum called dextran possessing a specific rotatory wer $[\alpha]_D = 201{\cdot}8°$. The presence of this gum the juice of fermented, frost-bitten canes may cause ors in analysis, and, in the case of syrups, may cause impression that starch-syrup has been added. Man- ol can generally be isolated from the fermented juices. her products of anaërobic fermentations occurring in factories are sulphuretted hydrogen, hydrogen and thane; serious explosions of these gases are not known. Among the aerobic fermentations which the thor has experienced, that due to the cellulose-producing ment, *B. xylinum*, is mentioned. The dried cell- embranes produced by this bacterium consist essentially cellulose; they contain only 0·2 per cent. of nitrogen, d, according to the author, do not contain chitine. e scums and deposits from most fermented juices ntain mannan. Chitine is a very important con- ituent of the scums which form every year on the surface molasses left over in the "hot room," and which are oduced by a species of *Citromyces*. These scums also ntain about 27 per cent. of fat, which closely resembles tter-fat in many of its characters, but which contains very high proportion of free acid, owing to lipolytic tion. The author has frequently observed the presence acetylmethylcarbinol in fermented juices; this appears be formed whenever alcoholic fermentation is arrested oxidising or acid-producing bacteria. Molasses and w sugars are not exempt from fermentative attacks, hich, however, are confined to the surface, where fficient hygroscopic moisture may be attracted to lute the liquid to an extent which permits of the develop- ent of organisms.—J. F. B.

ugar juices; Funk's process [Kieselguhr] for defecating ——. Brandt, Plötze and Schulz. Z. Ver. deutsch. Zuckerind., 1906, 90–93.

UNK'S process for defecating sugar juices effects an conomy in the lime-consumption by substituting for a ortion of the lime generally employed, a smaller pro- ortion of kieselguhr free from iron, which is cheaper. The ieselguhr is added to the crude juice, the temperature f which at the time of the addition must be about 90° C. n cases in which it has previously been necessary to use per cent. of lime for defecation in the ordinary manner, it as been found that, with the use of 0·05–0·1 per cent. f kieselguhr in the hot crude juice, 1 per cent. of lime ill suffice for the subsequent defecation. Saturation is arried out in the usual manner. No differences could be bserved in the appearance and composition of the juices nd subsequent products from the two processes. In ddition to an important economy of lime, the kieselguhr rocess offers advantages in the filtering and pressing, he quantity of scums is less, and consequently the quantity f dilute washings is reduced; there is a saving of space, wing to the smaller number of filters required, and here is an economy of filter-cloths. Owing to the smaller roportion of lime used, the time required for saturation curtailed.—J. F. B.

ugar manufacture; Unnoticed source of loss of sugar in ——. H. Pellet. Bull. Assoc. Chim. Sucr. Dist., 1906, **23**, 991–994.

HE author records a source of loss of sugar which akes place during its manufacture or refining. This loss s a kind of "volatilisation" which occurs whenever the team rising from hot juice, massecuites, or from the entrifugals escapes into the open air, the vapours from which, when inhaled, are noticed to have a sweet flavour. t can be demonstrated by holding a clean flask filled with cold water in the escaping vapour and by testing he liquid thus condensed, by the α-naphthol-sulphuric cid reaction. When it is considered that the free vaporatio" from the hot liquids in the course of manufac- ture amounts to 3—4 per cent. of the total volume, and that, at a temperature of 85° C., the condensed liquids have been found to contain as much as 2·5—5 grms. of sugar per litre, it will be understood that the losses from this cause may be very considerable. The volatilisation of the sugar probably occurs in the form of minute vesicles of juice carried in suspension in the vapours. When a 10 per cent. solution of sugar was distilled in a flask, care being taken to trap the vapours, no sugar could be detected in the distillate.—J. F. B.

Sugar; Prizes for the application of —— to industrial purposes. Bd. of Trade J., April 26, 1906.

THE French Syndicate of Sugar Manufacturers has voted a prize of 100,000 frs. (about 4000*l*.), with a view to stimulating research for new methods of employing sugar for industrial purposes. The conditions of the competition are as follows:—

1. The new application of sugar must be made solely for industrial purposes, not for the manufacture of any form of food.

2. The invention must give rise to an increased consumption in France of not less than 100,000 tons of refined sugar.

3. The prize will be awarded to the inventor as soon as the French official statistics prove that the new application of sugar has brought about an increased consumption of 100,000 tons in twelve months.

If it should appear necessary to lower or abolish the sugar tax in order to promote the success of the invention, the Syndicate will use every endeavour to obtain a rebate on the sugar used in the new industry. [T.R.]

Sugar; Reduction of German excise duty on — —. Bd. of Trade J., April 19, 1906.

A RESOLUTION has been passed by the Reichstag recommending the introduction during the present Session of a Bill to reduce the excise duty on sugar from 14 to 10 marks per 100 kilos. (from 7*s*. to 5*s*. per cwt.).

Should this measure be passed, the *import* duty on sugar (which consists of the excise duty, the "surtax" of 4 marks 40 pfg. on raw sugar and 4 marks 80 pfg. on refined sugar) will be correspondingly reduced. [T.R.]

Sugar mixtures; Analysis of ——. C. A. Browne, jun. XXIII., page 446.

UNITED STATES PATENT.

Crystallising sugar, &c.; Method of ——. V. H. Schütze, Riga, Russia. U.S. Pat. 817,010, April 3, 1906.

SEE Eng. Pat. 3792 of 1905; this J., 1905, 808.—T. F. B.

FRENCH PATENTS.

Grained sugar from syrups spun from the first-jet massecuites; Process for making ——. W. Raabe. Fr. Pat. 359,744, Nov. 24, 1905.

THE syrups spun from the massecuites of the first jet are diluted with water to a density of 60°—80° Brix., so as to bring them to the same concentration as the original syrup from which the first massecuite was boiled. The syrup is then heated and filtered and treated with a quantity of lime equal to 0·04—0·1 per cent. calculated on the beetroot equivalent of the syrup. The defecated liquor is then saturated in a continuous apparatus with sulphur dioxide until its alkalinity is reduced to the same point as that of the syrup from which the first massecuite was boiled (*i.e.*, 0·04—0·07 per cent.). The syrup is filtered and boiled to massecuite in the usual manner. This second product is stated to be of a purity equal to that of the first product.—J. F. B.

Starch ["Amyloid"] which gives liquefied pastes when heated with basic substances; Preparation of ——. J. L. Wolff. Fr. Pat. 360,091, Dec. 5, 1905.

STARCH, 25 kilos., is treated at the ordinary temperature for an hour and a half with 50 litres of a solution containing 2—4 parts per 1000 of potassium bichromate, and about 15 per cent. by weight of sulphuric acid. The

starch is then washed until the excess of acid is removed, and is dried at a temperature of about 30° C. If desired, the bichromate may be replaced by half its weight of permanganate. Starch thus treated gives a paste which, when heated in presence of traces of basic matter, *e.g.*, with ordinary water, becomes fluid and transparent. The liquefied pastes gradually gelatinise when cold, but are readily re-liquefied on heating. If the product of the oxidation be washed with distilled water instead of water containing traces of basic substances, and dried at 30° C., it may be converted into "soluble starch" by heating in the dry state at 80°—100° C. for a few hours.

—J. F. B.

GERMAN PATENT.

Sugar solutions; Process for the purification of —. I. Schetke-Raffay, geb. Hoflechner. Ger. Pat. 166,305, Jan. 22, 1905.

THE sugar solution is treated with a metallic sulphate, for example, ferrous sulphate, and then with a metal, such as zinc, in a fine state of division, the metal being of such a nature that it will cause the displacement of the iron from the sulphate in the form of hydroxide, with the evolution of hydrogen, whilst itself combining with the sulphuric acid. The metallic hydroxide thus produced forms insoluble compounds with the impurities present in the sugar solution, whilst the hydrogen exerts a bleaching effect.—A. S.

XVII.—BREWING, WINES, SPIRITS, &c.

(*Continued from page* 387.)

Malt-kilning; Notes on —— [*German system*]—H. Kropf. Woch. f. Brau., 1906, **23**, 169—171.

THE chief conditions for an ideal kiln are: perfect independence as regards temperature and draught of the upper and the lower hurdle-floors; uniform temperature and humidity of the air at all parts of the floor; rapid removal of moisture from the green malt at a low temperature. The author has devised a two-floor kiln answering these requirements, in combination with a Winter's withering floor in the uppermost part of the kiln. For the first six hours of the kilning, the air from the kiln proper is not passed to the withering floor, since it is too heavily laden with moisture. The withering is done at this time with fresh air from the furnace room, which is slightly warm, supplemented, if necessary, by a small proportion of hot air from the heating chamber. Afterwards, when the malt on the upper hurdle is nearly dry, the exhaust air from the kiln proper is passed through the withering hurdle, the supply of cooler air being also maintained in order to avoid a temperature above 30° C. in the withering malt. In this way the green malt retains only 20—23 per cent. of moisture after 12 hours' withering and is then loaded on the upper kilning hurdle. The independent regulation of the temperature on the upper hurdle of the kiln is effected by an arrangement of perforated pipes in the form of a net-work immediately below the hurdle. These pipes can be made to supply either cool, fresh air from the furnace room or hot air from the heating chamber, as desired. The curing process on the lower hurdle is effected generally with only a small draught, since after treatment on the upper hurdle the malt only retains 5—6 per cent. of moisture unless the evaporation has been purposely retarded.

For high-cured, pale malts, the withered malt is dried on the upper floor at a temperature not exceeding 50° C., the evaporation being accelerated by a full supply of cool air through the perforated pipes. The rapid removal of the moisture at a low temperature, both on the withering floor and on the upper kilning floor, enables the malt to withstand a higher temperature on the curing floor without loss of paleness; curing is finished at a temperature of 80°—85° C. for the last four hours. For dark, highly aromatic malts, the withered malt, containing 20—23 per cent. of moisture, is heated as soon as possible to a temperature of 67°—70° C. on the upper floor of the kiln, by closing the cool air inlets and thereby curtailing the evaporation. Under these conditions saccharification takes place, and can be regulated to any desired extent without affecting the mellowness of the endosperm. Afterwards, the cold air inlets are opened and the malt is dried off at a lower temperature, finally being cured and aromatised on the lower floor at a temperature of 100° C. By varying the temperature and rapidity of evaporation on the upper floor, any modification of the malt which may be desired can be obtained with certainty.

—J. F. B.

Malts and beers; The nitrogenous constituents of ——. R. E. Evans. J. Inst. Brewing, 1906, **12**, 209—223.

THE nitrogenous constituents of the wort are of the highest importance in determining the character and qualities of the beer, and although the nature of these is probably influenced most decisively by the nature of the barley and the process of malting, it is possible to control them to a certain extent in the mashing process. Given a wort containing a certain proportion of nitrogenous matters uncoagulated by the boiling process, the brewer has to ascertain what proportion of these is removable by the yeast during primary and secondary fermentation, and what proportion is incapable of removal. The removable nitrogenous matters or yeast nutrients may be divided into readily available nutrients and those which are only made available under starvation conditions when all the matters of the former class have been removed. The brewer can control these relations by diluting the total nitrogen supply by the addition of non-nitrogenous extract in the form of pure sugar. In this way, the author found that the percentage of the total nitrogen present, removed by the yeast during primary fermentation, could be varied between 29 and 42 per cent. under the conditions chosen. The most favourable result was obtained when the ratio of available yeast nutrient to fermentable extract was about 2:100. Further dilution tended to debilitate the yeast in consequence of the extra work entailed upon it. Moreover, when a vigorous secondary fermentation is required, it is desirable to leave some of the less readily available nutrient for the yeast at that stage. The nitrogenous matters remaining in the beer and incapable of serving as yeast nutrients, either in primary or secondary fermentation, may be of two classes: (*a*) the permanently and entirely soluble matters, which are perfectly stable, and which contribute to the flavour and "head" retaining qualities, being valuable factors in the "character" of the beer, and (*b*) the unstable, "high type" albuminoids which are very near the coagulating point, ready to be deposited as a "haze" when any change in the condition of the medium occurs. The unstable forms are capable of being measured to some extent by the addition of tannic acid to the beer previously neutralised by shaking it with chalk and determination of the nitrogen in the precipitate. Their presence is probably connected with the origin of the barley, foreign barleys being superior in this respect to English, and with faulty methods of malting and storage of the malt. The actual quantity required to produce a "haze" is probably very small, about 0·24 oz. per barrel, and it should not be impossible to find some natural means of eliminating such small quantities, other than by chilling and filtering.

—J. F. B.

Extracts [*Brewers'*]; *A study on* ——. *Part I.* W. S. Smith. J. Inst. Brewing, 1906, **12**, 229—251.

IT is well known that the finer the grist the higher is the yield of extract obtained; the only difficulty standing in the way of the utilisation of this advantage lies in the danger of "set" mashes, or clogging of the bed during the running off of the wort. For milling fine grists the author prefers smooth rolls of chilled cast iron, one of them being mounted on yielding bearings, set at distances ranging from 1/20—1/70 in. apart, the yield of extract being greater the closer the rolls. The different malts intended for the brew should be intimately mixed together, and then screened to separate the small corns, which should be ground separately in a smaller mill. A distinct advantage is gained by heating the malt to 140° F. on the kiln, 24 hours before milling. With fine grist, an efficient admixture of the grist and mashing

liquor is a prime essential requiring special care. An external mixing machine is of great utility for this purpose, the speed of travel being carefully regulated. The slower the rate, consistent with proper mashing, the better are the subsequent effects. With regard to the important question of the dimensions of the mash tun, the factors of depth of goods, drainage and yield of extract are closely allied, especially in relation to sparging. The ideal depth of goods in a 16-foot tun and at the finish of mashing with two barrels per quarter, is about 65 ins. wet dip. During the first quarter of the time occupied in filling the coppers it is best to allow the depth of goods to sink about 4 ins., making up for the contraction which occurs in the volume of the malt residues. The ratio of liquor to malt residues should be kept approximately constant, or a definite and regular rate should be adopted in the fall of the goods, violent changes being avoided. Deep mash tuns are not suitable for fine grist mashes; large, shallow tuns give thinner deposits of impervious material, though they require perhaps rather larger quantities of sparging liquor. The maintenance of a uniform depth of goods minimises the danger of "flooding" when the rakes are worked slowly at half-time; in the author's opinion half an hour's rest after raking, is beneficial, and increases the uniformity of extraction.—J. F. B.

Yeast; Mechanism of the acclimatisation of —— towards sulphurous acid. E. Pozzi-Escot. Bull. Assoc. Chim. Sucr. Dist., 1906, **23**, 1021—1022.

THE author expresses his disagreement with the conclusions of Gimel (this J., 1906, 192) that the acclimatisation of yeast towards the presence of sulphurous acid in the media is due to an oxidising action of the yeast. Gimel's conclusions are stated to be based on erroneous experimental results. The author maintains that "the yeast defends itself against the toxicity of sulphurous acid by a reducing action."—J. F. B.

Fermenting vats; Paraffining of ——. B. Franzl. Letters on Brewing (Hantke's), 1906, **5**, 223—224.

THE author writes favourably concerning the use of paraffined fermenting vessels, in which the beer never acquired a woody taste, whilst the clarification was always satisfactory. The beer has had no effect whatever on the paraffin, although, in some cases, a single coating has been used for five years.—T. H. P.

Alcohol Bill in the United States. Chem. and Drug., April 28, 1906.

THE Committee on Ways and Means, which sat at Washington on March 30, authorised a favourable report on the Free Alcohol Bill, which removes the internal revenue duty from denatured alcohol for use in the arts and sciences. The Bill has the approval of Commissioner Yerkes, and it is estimated that the annual loss in revenue will not exceed 500,000 dols., and may not be more than 300,000 dols. It is said that the Bill will be of great benefit to manufacturers, and will afford an enlarged market for farm-products from which alcohol is made. The sale of denatured alcohol as a beverage or for liquid medicinal purposes is forbidden by the measure, under penalty of a fine not to exceed 5,000 dols., or five years' imprisonment, or both, in the discretion of the Court. [T.R.]

ENGLISH PATENTS.

Malt; Preparation of —— by means of chloride of lime or other hypochlorite salts. J. Effront, Brussels. Eng. Pat. 1639, Jan. 22, 1906.

THE claims made are for: (1) A method of preparing malt by adding to the steeping water a neutralised solution of a hypochlorite and maintaining the proportion of chlorine in the steeping water during the whole operation at 0·5 to 0·7 grm. per litre by subsequently adding neutralised hypochlorite solution. (2) A modification of (1), consisting in treating the malt with neutralised hypochlorite solution during the germination process. (3) A further extension, which consists in moistening or washing green malt for distilling purposes, and particularly for the manufacture of artificial yeast, with neutralised hypochlorite solution, before use. —T. H. P.

Yeast; Method for the production of dry ——. H. Hahn and C. Reiser, Munich, Germany. Eng. Pat. 11,453, May 31, 1905.

SEE Fr. Pat. 348,573 of 1904; this J., 1905, 509.—T. F. B.

Brewers' worts; Apparatus for cooling ——. E. F. Daniel and G. Thornley, Burton on Trent. Eng. Pat. 19,724, Sept. 29, 1905.

THE refrigerator for brewers' worts consists of a closed casing containing a large number of superposed horizontal tubes over the external surface of which the hot wort is caused to flow in a very thin layer. The cooling medium is passed through the interior of the tubes, which are partially filled with metal cores, so as to leave only a very narrow annular space through which the cooling medium circulates. By thus reducing the body of cooling liquid presented to the heated surface a more efficient interchange of heat between the two liquids is obtained. —J. F. B.

Briquettes; Manufacture of ——. [*Utilisation of distillers' refuse.*] Baron Armstrong. Eng. Pat. 6784, March 30, 1905. II., page 420.

UNITED STATES PATENT.

Pasteurising apparatus [for beer]. C. H. Loew, Lakewood, Ohio. U.S. Pat. 817,495, April 10, 1906. (See also U.S. Pat. 808,668; this J., 1906, 131.)

THE apparatus for pasteurising beer in bottles comprises a pasteurising chamber containing perforated trays, on which the bottles are packed, a spraying mechanism within the chamber connected with a water-supply, and means for gradually heating the water without interrupting its flow until a predetermined temperature is reached and for maintaining that temperature. The sprayed water, after passing over the bottles on the trays, is collected in a drip-tank at the bottom of the apparatus, from which it is pumped to the water-heating chamber, where it is again heated to the desired temperature b means of a steam pipe controlled by a thermostat. Means are provided for again returning the heated water from the heating-chamber to the spraying devices, also for gradually lowering the temperature of the water when the process of pasteurisation is completed.—J. F. B.

FRENCH PATENTS.

Beer in bottles; Process and apparatus for pasteurising ——. C. H. Loew. Fr. Pat. 360,177, Dec. 7, 1905.

SEE U.S. Pats. 808,668 and 817,495 of 1906; this J., 1906, 131, and preceding these.—T. F. B.

Beer; Product and process for the preservation of ——. H. Canonne. Fr. Pat. 360,107, Feb. 13, 1905.

A PRODUCT, which is stated to ensure the perfect stability and preservation of beer, is composed of 90 parts of calcium carbonate, and 10 parts of ferric oxide. The mixture is used in the proportion of 50 grms. per ton of barley malt. For use, 100 grms. of the substance are suspended in 10 litres of water, and are added to the mash-tun when the mashing of the grain is three-quarters finished.—J. F. B.

Fermentable liquids, particularly wines and spirits; Apparatus for heating or cooling ——. Soc. Quelin et Perras. Fr. Pat. 360,257, Dec. 8, 1905.

THE apparatus consists of a vessel containing water beneath which is a hearth, the chimney from which rises through the vessel and is surrounded to a considerable height by the water to be heated. The wine or other liquid passes through a coil immersed in the water and surrounding the chimney of the furnace. When it is

required to cool the wine in order to arrest fermentation, the fire is extinguished and cold water is allowed to circulate through the vessel.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 388.)

(A.)—FOODS.

Bread; Alcohol in — —. O. Pohl. Z. angew. Chem., 1906, **19**. 668–669.

The distillations were effected in a Papin's digester of about 8 litres capacity, into the cover of which a pipe was fitted communicating with a Liebig condenser. The charge consisted of 2 litres of water and 990 grms. of bread, divided into small cubes. The distillate, measuring about 500 c.c., had a strong odour of new bread, an acid reaction, and required 1·15 c.c. of N/1-potassium hydroxide solution for neutralisation. The united distillates (about 2 litres) from four charges, representing 4419 grms. of bread, were saturated with sodium chloride and redistilled in a flask fitted with a Hempel still-head, until about half the volume had come over. This was again saturated with sodium chloride, reduced to half its bulk by redistillation, and this operation repeated until the final distillate measured 120 c.c. The latter was then saturated with calcium chloride and distilled. The distillate, measuring 50 c.c., had a sp. gr. of 0·9885, corresponding to 6·66 grms. of alcohol in 100 c.c., so that 100 grms. of bread contained 0·0753 grm. of alcohol.—D. B.

Acids; Detection of some — — [*Boric acid in milk*]. V. Castellana. XXIII., page 445.

(B.)—SANITATION; WATER PURIFICATION.

English Patents.

Water; Apparatus for softening and purifying — —. T. R. Wollaston, Manchester. Eng. Pat. 15,872, Aug. 3, 1905.

The crude water is delivered into the compartments of a tipping bucket or water-wheel. This bucket is mounted over a trough divided by a cross-partition, a portion of the contents of the bucket being discharged on one side and the other portion on the other side of the partition. The position of the bucket relatively to the partition is capable of accurate adjustment, so that the proportions of the contents falling on the two sides of the partition can be varied according to the hardness of the water. The water delivered on one side of the partition passes into the mixing chamber and clarifying tank, whilst the water delivered on the other side falls on a tray containing slaked lime, and thence down a pipe to the bottom of a chamber in which it is clarified by upward flow, and from which it emerges at the top in the form of clear lime water, which passes to the reaction chamber in exactly the same proportions as the bucket was adjusted to deliver. Soluble reagents are supplied, if required, by displacement of a regulated volume from a reagent tank by means of a reciprocating body operated by the movement of the bucket. Clarification, removal of froth, and final filtration of the softened water are effected in the usual manner.
—J. F. B.

Liquids [*Water*]; *Purifying apparatus for* ——. C. Schmidt, Vienna. Eng. Pat. 1158, Jan. 16, 1906.

The dry reagents for the precipitation are supplied to the water in a fine state of division and in the right proportion from a tank by means of a conveyor-worm which rotates beneath in a chamber with an outlet opening reaching not quite to the bottom. The worm-conveyor may be driven by the water to be purified, and may have threads in the opposite direction at one end, with the object of preventing precipitating substances being thrown and packed against the front wall of the vessel.
—C. A. M.

(C.)—DISINFECTANTS.

Coal-tar oils; Process for preparing dermatologically active, high-boiling ——, *which do not darken.* Knoll und Co. Ger. Pat. 166,975, May 31, 1903.

Heavy coal-tar oils, of b. pt. 300° C. and upwards, are washed with acid and alkali in the usual way, and then treated once or more with several per cent. of concentrated sulphuric acid at an elevated temperature, with or without addition of an oxidising agent: the product is then thoroughly washed with alkali, and distilled, preferably *in vacuo*, in an apparatus in which it does not come into contact with base metals; this latter precaution is necessary to prevent the oils darkening on keeping
—T. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

(*Continued from page* 389.)

Swedish "Kraft" paper from Adansonia fibre. C. Beadle and H. P. Stevens. Paper and Pulp, 1906, **25**. 195.

The Adansonia fibre, obtained from the bast of the Baobab tree, is, next to the Japanese fibres, probably one of the most suitable for making unbleached papers of the strongest quality. The bast is chopped, boiled with dilute soda-lye under a pressure of 3–4 atmospheres for eight to ten hours, and is beaten to a "wet" pulp between blunt knives; it does not lend itself to bleaching. Since the price of the bast delivered in England amounts to about 10*s.* per cwt., and as the loss during the working up of the pulp is nearly 50 per cent. and the process of manufacture is an expensive one, this fibre can, under present conditions of collection and importation, only be employed for certain very special purposes, *e.g.*, for the manufacture of emery-papers, &c. With organised production, however, there is a prospect of lower prices in the future.—J. F. B.

Cellulose and paper industry of Sweden. For. Off. Ann. Ser. No. 3500.

The past year shows a great advance in both the prices of sulphite pulp and the amount manufactured. The former, which in 1903 were down at 6*l.* 7*s.* 9*d.* f.o.b., rose in 1905 to 8*l.* 6*s.* 8*d.* and upwards.

A number of new mills are in course of erection, but the workshop strike has probably kept back some of them. The progress made by the sulphite industry will be seen from the following figures:—1891, 24,000 tons; 1896, 62,000 tons; 1901, 140,000 tons; 1905, 270,000 tons.

Sulphate cellulose shows no corresponding increase, but as regards prices it followed pretty nearly those of sulphite.

The paper industry on the whole did well during 1905. The mills were kept fully occupied and there was some improvement in prices, especially as regards sulphate cellulose and strong papers. The better prices obtained for the above-mentioned kinds of paper are ascribed to an agreement made several years ago between the local manufacturers to prevent undue rivalry with each other, while makers of other papers, especially sulphite bag papers, paper for newspapers, and packing paper, are said to be still indulging in the keenest competition. The export of paper generally is steadily increasing. Of the amount that is exported, the United Kingdom at present takes the largest share. So many new factories are either planned or actually being erected that a very considerable increase is expected soon in the production of sulphite cellulose. Of this increase it is calculated that about 100,000 tons more pulp will be exported annually in a half-manufactured condition, while a certain amount will remain in the country to be worked up into paper.

The following table shows the amount of paper

exported from Sweden to the United Kingdom during the last three years:—

Year.	Printing Paper in Rolls.	Printing Paper not in Rolls.
	Cwts.	Cwts.
1903	472,116	742,161
1904	536,926	792,300
1905	558,996	842,452

The total value of paper exported to the United Kingdom during 1905 is estimated at over 1,000,000*l.*, to which may be added a considerable amount of pulp sent to the British markets. [T.R.]

Cellulose and paper industry of Norway For. Off. Ann. Ser. No. 3555.

The following are the figures for the exports of wood-pulp, cellulose, &c., from Norway:—

	Quantity.			Value.	
	Average for 1901–04. Tons.	1904. Tons.	1905. Tons.	1904 £	1905. £
Wood-pulp—					
Dry	19,526	18,395	21,085	66,433	90,678
Wet	326,645	335,917	321,822	578,322	689,267
Cellulose—					
Dry	109,650	113,497	130,093	851,233	1,071,872
Wet	14,438	14,928	15,203	53,905	63,828
Packing paper	32,573	33,160	33,458	307,661	317,522

The figures quoted from the official statistics include Swedish pulp and cellulose re-exported; the amount of Swedish cellulose thus treated has increased considerably of recent years from 12,774 tons in 1901 to nearly 28,000 tons in 1903, though a slight drop to 23,000 tons occurred in 1904.

The demand for cellulose has increased of late years; better prices have been realised in 1905 than for several years past, and many of the makers in the Drammen district are said to have disposed of their production over 1906 and 1907. The stocks at the end of the year are very moderate and prices keep firm. It is, however, to be questioned whether this improvement in the cellulose industry will last, as there is a tendency to build new factories. Two large new factories are reported in Norway, while old factories are being extended. Of the new production at least 40,000 tons are expected on the market in 1906, and the increase by the close of 1907 or early in 1908 is estimated at 150,000 tons.

The high prices of mechanical wood-pulp which, owing to scarcity of water power, ruled during the winter of 1904-05, proved of no stability. As soon as the spring flow enabled mills to work at full power, prices declined rapidly from 2*l.* 10*s.* to 2*l.* f.o.b. per ton moist; during the summer from 1*l.* 17*s.* to 2*l.* 7*s.* f.o.b. per ton moist, wrapped in hessians, were the best prices obtainable for ordinary brands. A recovery occurred in the autumn owing to heavy rains, thus nearly balancing the earlier reduced output. The year closed with ample stocks but few inquiries. Of late it has become more and more usual to ship wood-pulp from Norway unpacked, that is, in bales bound together with iron wire and protected by sticks, instead of in canvas or jute as formerly. This is stated to be due to difficulties in inducing the authorities to grant the same drawback on jute packing materials that is accorded in Sweden. [T.R.]

English Patents.

Paper or card; Sizing ——. F. Dobler, Paris. Eng. Pat. 14,789, July 18, 1905.

See Fr. Pat. 350,035 of 1904; this J., 1905, 984.—T.F.B.

Celluloses; Utilisation of Ulex Europeus —— for manufacturing artificial silk, celluloid, plastic matters, guncotton, and for any other uses. G. P. Horteloup, Paris. Eng. Pat. 21,505, Oct. 23, 1905. Under Int. Conv., Oct. 24, 1904.

See Fr. Pat. 347,353 of 1904; this J., 1905, 344.—T.F.B.

United States Patents.

Papermaking; Process of dissolving size for ——. B. Kniffler, Stoneham, Mass. U.S. Pat. 816,863, April 3, 1906.

The process consists in heating a measured volume of rosin size, spraying the liquefied size into a measured volume of hot water to produce an emulsion, agitating the emulsion, and adding thereto a measured volume of cold water.—J. F. B.

Papermaking; Apparatus for dissolving size for ——. B. Kniffler, Stoneham, Mass. U. S. Pat. 816,864, April 3, 1906 (see preceding abstract).

The apparatus consists of means for heating the size, and a receiver for the liquefied size; the receiver has a perforated discharging plate located at the upper end of the perforated tube of an emulsifying chamber. This emulsifying chamber consists of two concentric tubes, the inner one being perforated and attached to the outer tube at both ends. The liquefied size is discharged through a perforated plate at the top of the inner tube, whilst jets of hot water are forced through the perforations in the walls of the inner tube, so as to strike the jets of size at an angle, and thereby disintegrate them, so as to form an emulsion. The emulsion is received in a tank, which is connected with another tank in which the emulsion is mixed with cold water.—J. F. B.

Papermaking; Process for dissolving size for ——. B. Kniffler, Stoneham, Mass. U.S. Pat. 816,865, April 3, 1906. (See preceding abstracts.)

A measured volume of rosin size is heated and is then subjected in the form of small jets or streams to the action of forcibly expelled jets or streams of hot water, in predetermined relative proportions, to disintegrate the jets of size and produce an emulsion. This emulsion is then added to a measured volume of cold water.
—J. F. B.

Filaments and films; Manufacture of —— from viscose. C. N. Waite, Assignor to S. W. Pettit. U.S. Pat. 816,404, March 27, 1906. V., page 426.

Paper for lithographic prints; Process of producing ——. L. W. Noyes, Mechanicsville, N.Y. U.S. Pat. 816,497, March 27, 1906.

The web of paper is first passed through a solution of size, to fill up the pores, and to provide a homogeneous surface; the excess of size is removed and the paper is then dried. An enamel-coating composition consisting essentially of casein is then spread on the web, which is finally dried by hot air, all the operations being performed in one continuous process.—J. F. B.

French Patents.

Paper and cardboard; Apparatus for impregnating —— on the machine in the course of manufacture. F. Dobler. Fr. Pat. 359,930, Feb. 7, 1905.

In order to impregnate the moist web of paper after it leaves the press rolls, it is necessary to support it on moving bands. These bands, which also serve for applying the impregnating solution, consist of aprons made of a material possessing a smooth, impermeable surface, *e.g.*, caoutchouc, in order to avoid frothing. The lower band dips underneath the surface of the impregnating solution and carries a thin layer of the liquid to the under-side of the paper. The same solution is applied to the upper surface of the paper by spraying it over the surface of the upper band. Both bands with the paper between them then pass between a pair of press-rolls and the impregnated paper passes on to the drying cylinders.
—J. F. B.

Papermaking materials; Process for bleaching ——. A. Gagedois. Fr. Pat. 360,158, Dec. 7, 1905.

For the manufacture of white pulp from materials hitherto regarded as being incapable of being fully bleached, the materials or pulps are boiled once or several times with a lime or soda lye in the ordinary manner, and are washed.

perfectly free from the reagent. The lye-boils are followed by hypochlorite treatment, once or several times, and the hypochlorite is thoroughly removed by washing. Bleaching proper is then conducted by agitating the materials for four to six hours in a solution of alkali peroxide and silicate. This solution contains 0·5—3 kilos. of peroxide and 10—30 kilos. of liquid silicate of 35° B. per 100 kilos. of material. During the process the temperature is gradually raised to about 80° C. in order to decompose the peroxide. The material is washed and is then agitated with a solution of soap containing caustic alkali, at a temperature of 40°—50° C. for one hour. The material is drained, treated again with hypochlorite, washed, and finally neutralised with thiosulphate solution. For the manufacture of white paper from coloured rags, the rags are steeped in a very dilute solution of nitric acid for 10—12 hours, prior to treatment in the above manner.

—J. F. B.

Paper; Process of making —— impermeable. Mme. N. L. Duryea *née* Smith. Fr. Pat. 360,276, Dec. 9, 1905.

The paper is first steeped in a hot solution containing potassium caseate, 25 parts; soap, 12 parts; gelatin, 8 parts; and water, 955 parts. It is then drained and passed into a second bath composed of calcium acetate, 50 parts, and water, 950 parts. After soaking in this for a few minutes, the paper is dried, and is then coated with a solution of paraffin wax, 22 parts in petroleum benzine 928 parts, finally being dried and subjected to the action of hot rollers.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 393.)

Pinene and camphene; Action of mercuric acetate solution on ——. [*Detection of camphene in essential oils.*] L. Balbiano. Reale Accad. dei Lincei, 1905; through J. Pharm. Chim., 1906, **23**, 397.

Pinene.—When 25 grms. of pinene are agitated at intervals with a solution of 174·5 grms. of mercuric acetate in 700 grms. of water, the pinene is oxidised into Δ^6-(6-) hydroxymenthenone (2).

Camphene.—With the same reagent, under similar conditions, camphene forms an additive crystalline compound, $C_{10}H_{16}O(HgC_2H_3O_2)_2$, insoluble in water and in ether, and therefore readily purified. When suspended in water and treated with a current of hydrogen sulphide this body is decomposed, liberating camphene.

To detect camphene in an essential oil, a solution of the same in an equal volume of benzene is agitated with a 25 per cent. aqueous solution of mercuric acetate, and set aside for 30 days. The crystalline compound thus formed is collected, purified, and the terpene regenerated with hydrogen sulphide.—J. O. B.

Compounds with an allyl side chain: Differentiation of —— from isomerides with a propenyl chain, by means of mercuric acetate. L. Balbiano. Reale Accad. dei Lincei, 1905, through J. Pharm. Chim., 1906, **23**, 395—397.

With compounds having an allyl side chain, represented by the generic formula $R.CH_2.CH:CH_2$, such as methylchavicol, safrol, methyleugenol and apiol, saturated aqueous solution of mercuric acetate forms mercury compounds having the constitution, $R.C_3H_5(OH)HgC_2H_3O_2$, from which the original body may be liberated by treatment with hydrogen sulphide. With the isomeric propenyl compounds, such as anethol, isosafrol, isomethyleugenol, and isoapiol, of the general formula $R.CH:CH.CH_3$, mercuric acetate acts as an oxidising agent, and the propenyl compounds fix two hydroxyl groups to the ethylene nucleus, giving compounds with the formula $R.CHOH.CHOH.CH_3$. Mercuric acetate affords, therefore, a ready means of distinguishing these isomerides, for which, hitherto, almost the only distinctive reaction has been that of nascent hypoiodous acid, as shown by J. Bougault (Comptes rend., 1900, **132**, 561).

Safrol is taken as a type of the compounds with an allyl side chain. When 10 grms. are agitated with 100 grms. of a 20 per cent. aqueous solution of mercuric acetate, the safrol is slowly transformed into a dense syrupy liquid; after eight days, this is separated, washed with water, and dissolved in absolute alcohol. The addition of 10 or 12 vols. of anhydrous ether precipitates a trace of a solid body, which is filtered off. On distilling off the solvent from the filtrate, the syrupy residue is found to have the constitution $CH_2O_2:C_6H_3.C_3H_5(OH)HgC_2H_3O_2$. On passing hydrogen sulphide through this, safrol is regenerated.

Anethol is typical of the compounds with a propenyl chain. Twenty grms. are melted and shaken with 86 grms. of mercuric acetate dissolved in 344 grms. of water. Oxidation takes place almost immediately, with the formation of mercurous acetate; after 15 or 20 days the deposit of this salt is mixed with metallic mercury and the supernatant aqueous solution acquires a yellowish tint. The mass is then extracted with ether, the ethereal solution is washed with sodium carbonate, and the ether distilled off. The residue thus obtained is the glycol $CH_3O.C_6H_4.CHOH.CHOH.CH_3$.—J. O. B.

Urotropine (Hexamethylenetetramine); Decomposition of ——. R. Ischidzu and T. Inouye. J. Pharm. Soc., Japan, 1906, 1. Chem. Centr., 1906, **1**, 1087—1088.

The authors have investigated the decomposition of urotropine, $(CH_2)_6N_4$, especially by acids, *viz.*, boiling hydrochloric and acetic acids, dilute sulphuric, hydrochloric, acetic, lactic, succinic and salicylic acids, and Japanese saké. In the decomposition by acids, the chief products are formaldehyde, carbon dioxide, ammonia and methylamine. The beginning of decomposition and the amounts of the different products formed, depend upon the quantity of acid, its concentration, the temperature and the duration of the action. With a moderate action of hydrochloric or acetic acid for a definite period, 2 mols. each of ammonia and methylamine are formed from 1 mol. of urotropine. With increase of temperature, duration of action, and concentration of acid, the formation of ammonia increases, whilst that of methylamine diminishes. Under suitable conditions, however, the quantity of methylamine produced is so large that the reaction can be used practically for the preparation of that compound. On distilling urotropine with dilute hydrochloric or sulphuric acid, formaldehyde is found in the distillate (95 parts per 100 parts of urotropine; theoretically, 128:100). Urotropine is more stable in alkaline than in neutral solutions: even by simple boiling with water, formaldehyde is produced. A not inconsiderable quantity of formaldehyde is also produced in saké preserved by addition of urotropine.—A. S.

Phenyldimethylpyrazolone [Antipyrine] and its more important derivatives; Isonitroso-reaction of ——. F. Sperling. XXIII., page 445.

Acids; Detection of some ——. V. Castellana. XXIII., page 445.

English Patent.

ω-Alkylamino-ethylbenzoates; Manufacture of ——. A. Zimmermann, London. From Chem. Fab. vorm. E. Schering, Berlin. Eng. Pat. 15,456, July 27, 1905.

Alkylamino-ethanols or their salts are treated under suitable conditions with a benzoylating agent, such as benzoic anhydride or benzoyl chloride. The benzoylated product is isolated and purified either in the form of the free base or of one of its salts, *e.g.*, the hydrochloride or oxalate. These compounds are utilised as local anæsthetics.—J. F. B.

United States Patent.

Magnesium perborate. O. Liebknecht, Frankfort on Maine, Germany, Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 816,925, April 3, 1906.

See Ger. Pat. 165,279 of 1904; following these.—T.F.B.

Dialkylbarbituric acids; Process of making ——. M. Conrad, Aschaffenburg, Germany. U.S. Pat. 817,159, April 10, 1906.

See Fr. Pat. 354,452 of 1905; this J., 1905, 1125.—T. F. B.

Benzoylalkylaminoethanols and process of making same. T. Emilewicz, Assignor to Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. U.S. Pat. 817,164, April 10, 1906.

See Eng. Pat. 15,456 of 1905; preceding these.—T. F. B.

Acetylene chloride; Process of making ——. H. Precht, Neustassfurt, Germany. U.S. Pat. 817,188, April 10, 1906.

See Fr. Pat. 355,776 of 1905; this J., 1905, 1255.—T.F.B.

French Patents.

Dialkylbarbituric acids; Process of preparing ——. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 359,820. Feb. 3, 1905.

See U.S. Pat. 790,116 of 1905; this J., 1905, 749.—T.F.B.

Dialkylmalonylureas; Process of making ——. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 360,334. Dec. 11, 1905. Under Int. Conv., Jan. 9, 1905.

See Eng. Pat. 26,275 of 1905; this J., 1906, 233.—T. F. B.

German Patents.

Morphine alkyl ethers; Process for preparing bromalkylates of ——. J. D. Riedel, A.-G. Ger. Pat. 166,362, May 28, 1904.

The alkyl ethers of morphine (*e.g.*, codeïne, &c.) are converted into the quaternary bases by means of alkyl bromides in the usual manner, or a quaternary morphine bromoalkylate is converted into its alkyl ethers in the known way, or morphine is treated with 1 mol. of alkali and 2 or more mols. of alkyl bromide; each of these methods results in the formation of the bromoalkylates of codeïne or its homologues, which are of medicinal value. (See also U.S. Pat. 780,619 of 1905, and Ger. Pat. 158,620 of 1903; this J., 1905, 209 and 750.)—T. F. B.

Eserine; Process of preparing a salt of —— which does not become coloured. E. Merck. Ger. Pat. 166,310, Feb. 24, 1905.

A suitable solution of eserine is treated with sulphurous acid, and the resulting solution evaporated. The salt thus obtained differs from the sulphate and other salts of eserine in that its aqueous solutions do not turn red, but remain colourless.—T. F. B.

Coal-tar oils; Process for preparing dermatologically active, high-boiling —— which do not darken. Knoll und Co. Ger. Pat. 166,975, May 31, 1903. XVIIIC., page 440.

Peptone preparation containing iron thiocyanate; Process for preparing ——. M. Baum. Ger. Pat. 166,361, Oct. 3, 1903.

A peptone preparation containing iron thiocyanate is obtained by treating iron thiocyanate, containing excess of ferric hydroxide, with an aqueous solution of albumin, and mixing the precipitate with pepsin-hydrochloric acid ("Pepsinsalzsäure").—T. F. B.

Tri-iminobarbituric Acids; Process for preparing ——. E. Merck. Ger. Pat. 165,692, Feb. 11, 1904.

Tri-iminobarbituric acids are obtained by condensing guanidine (or its homologues or derivatives) with malonitrile or its mono- or di-alkyl derivatives, in presence of alcoholates, alkali metals, or alkali amides, or even without condensing agents.—T. F. B.

Diiminobarbituric acids; Process for preparing ——. E. Merck. Ger. Pat. 166,448, Feb. 11, 1904.

Malonitrile, or a mono- or dialkyl malonitrile, is condensed with urea or a suitable derivative thereof, with or without the assistance of a condensing agent; the product of the reaction is a 4.6-di-iminobarbituric acid. (Compare preceding abstract.)—T. F. B.

Barbituric acid derivatives; Process for converting 5-alkylated diamino-oxy- and triaminopyrimidines into the corresponding ——. E. Merck. Ger. Pat. 165,693, Feb. 11, 1904. Addition to Ger. Pat. 156,385, July 12, 1903.

Alkylbarbituric acids are obtained by heating with dilute acids the corresponding 5-alkyl-4.6-diamino-2-oxypyrimidines or -2.4.6-triaminopyrimidines (di- or tri-iminobarbituric acids; see two preceding abstracts), 2 or 3 mols. of ammonia being eliminated.—T. F. B.

C.C-Dialkyl-2-arylimino- and -2-arylhydrazinobarbituric acids; Process for preparing ——. A. Einhorn. Ger. Pat. 166,266, Dec. 11, 1904.

Dialkylbarbituric acids are converted by condensation with aromatic amino-compounds or hydrazines, into dialkyl-2-aryliminobarbituric acids or dialkyl-2-arylhydrazinobarbituric acids respectively. These derivatives are converted into dialkylbarbituric acids by heating with mineral acids.—T. F. B.

4.5-Diamino-2.6-dioxypyrimidines; Process for preparing ——. E. Merck. Ger. Pat. 166,267, March 7, 1905. Addition to Ger. Pat. 161,493, March 3, 1904.

4-Amino-5-isonitroso-2.6-dioxypyrimidines (see Ger. Pat. 161,493; this J., 1905, 1030) are reduced electrolytically to 4.5-diamino-2.6-dioxypyrimidines; the latter are thus obtained in a much purer condition than when reduction has been effected by means of metals.—T. F. B.

Zinc perborate; Process of preparing ——. Deutsche Gold- und Silber-scheide Anstalt. vorm. Roessler. Ger. Pat. 165,278, July 14, 1904.

Zinc perborate is obtained either by the action of sodium peroxide or its hydrate, and boric acid or sodium perborate on a zinc salt, or from boric acid and zinc peroxide hydrate. For example, 287 parts of crystallised zinc sulphate are dissolved in about 600 parts of water, 102 parts of boric acid are stirred in, and then 80 parts of 97 per cent. sodium peroxide are added, the solution being kept cool, and stirred for about half an hour. The product is freed from sodium sulphate by decantation with water. It is a white, amorphous powder, applicable to dermatology. —T. F. B.

Magnesium perborate; Process of preparing ——. Deutsche Gold- und Silberscheide Anstalt vorm. Roessler. Ger. Pat. 165,279, Oct. 30, 1904. Addition to Ger. Pat. 165,278 (see preceding abstract).

The processes for preparing zinc perborate, described in the preceding abstract, are also applicable to the preparation of magnesium perborate, the magnesium salt being substituted for the zinc salt in each case. Magnesium perborate is a very stable, white, amorphous substance, and is said to be of value in bleaching processes and also medicinally.—T. F. B.

Isovaleric acid benzyl ester; Process of preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 165,897, Aug. 16, 1904.

The benzyl ester of isovaleric acid is obtained in the usual manner from benzyl alcohol and a derivative of isovaleric acid. It is said to possess sedative properties. An isomeride, prepared from methylethylacetic acid, has no definite physiological action.—T. F. B.

Tannin with formaldehyde and acid amides; Process for preparing condensation products from ——. A. Voswinkel. Ger. Pat. 165,980, Nov. 22, 1904. Addition to Ger. Pat. 160,273, Nov. 6, 1903 (this J., 1905, 1030).

Tannin and formaldehyde are condensed with acid amides other than urea and the urethanes, by the method described in the principal patent. The products have the general formula $C_{14}H_9O_9.CH_2.NH.CO.R$, and are stated to be of medicinal value.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 393.)

Development; The theory of alkaline —— with notes on the affinities of certain reducing agents. S. E. Sheppard. Chem. Soc. Trans., 1906, **89**, 530—550.

At moderate concentrations, 1 mol. of hydroxylamine reduces 1 mol. of silver salt, but, in the case of great dilutions, 2 mols. The oxidation product in the first case is nitrogen, and in the second, nitrous oxide: 1 mol. of hydrogen peroxide reduces 1 mol. of silver salt, probably according to the equation $2H_2O_2+Ag_2O=2Ag+H_2O+2O_2+H_2$, hydrogen being one of the products of the reaction. The following table gives a summary of the results obtained: R is the reducing power, *i.e.*, the number of molecules of silver bromide reduced by 1 mol. of the developer. K = velocity of development in N/10 solution at 20° C. T.C. = temperature coefficient (=K+10/K). F = energy, or concentration of bromide producing the same retardation as N/100 bromide with ferrous oxalate:—

Developer	R.	K.	T. C	F.
Ferrous oxalate	1	0·061	1·70	0·01 N
Hydroxylamine	1	0·305	2·10	0·0113 N
Hydrogen peroxide ..	1	—	—	—
Quinol	2	0·146	2·80	0·0052 N
p-Aminophenol	1—2*	0·550	1·5	0·0073 N
Methyl-*p*-aminophenol	1—2*	0·500	1·25	0·034 N

* According to concentration.

The developing equivalence of alkali hydroxides is the same as their affinity constants as bases, the effect depending only on the concentration of the hydroxyl ions. The value of carbonates and other salts in development, depends, therefore, solely on their hydrolysis and on the formation of hydroxyl ions thereby. A curious result was obtained with quinol, using N/20 alkali hydroxide; up to N/40 quinol, the velocity of development is proportional to the concentration of the quinol, but at N/40 a maximum is reached, which is maintained up to a concentration of N/20, after which the velocity declines. With N/40 quinol, increase of alkali up to N/20 increases the velocity at a greater rate than the concentration, but a maximum is attained at 1 mol. of quinol to 2 of alkali. In the case of *p*-aminophenol, the velocity of development was approximately proportional to the concentration of the alkali, and inversely to the volume when alkali and reducer were in equimolecular proportions.—T.F.B.

United States Patent.

Photography; Reducing agent or composition for use in ——. H. E. Smith, London. U.S. Pat. 816,751, April 3, 1906.

See Eng. Pat. 6276 of 1905; this J., 1905, 751.—T. F. B.

French Patent.

Photographic images; Process of obtaining ——. G. N. Pifer. Fr. Pat. 359,768, Nov. 6, 1905.

See U.S. Pat. 804,038 of 1905; this J., 1905, 1255.—T.F.B.

German Patent.

Catechol; Process for preparing alkali compounds of ——. [*Photographic developers.*] Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 164,666, Aug. 19, 1904.

Alkali salts of catechol of the general composition, $C_6H_4(OH)(OM).C_6H_4(OH)_2$, are obtained by treating catechol with a solution of the theoretical quantity of alkali hydroxide or of a salt with an alkaline reaction: the sulphites are most suitable, as they prevent oxidation of the catechol. This affords a simple method of isolating catechol from impure, coloured solutions, and obtaining it in a form suitable for photographic purposes, the new compounds being readily crystallisable.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

(*Continued from page* 393.)

Explosion; Circumstances attending an —— which occurred at Nether Walstead, near Hayward's Heath, Sussex, on Oct. 26, 1905. By Capt. M. B. Lloyd, H.M. Inspector of Explosives.

A quantity of gelignite cartridges stored in a portable copper magazine for use in blasting operations in the construction of a sewer, exploded in the vicinity of a shed and killed the ganger who was standing in the doorway of the shed. Near the doorway was a "fire-devil," and the evidence indicates that the box had been placed over the fire by the ganger in order to thaw the cartridges which had frozen, owing to the cold weather prevailing at the time, suitable warming pans not having been supplied. The contractors are, it is considered, partly to blame for not having provided warming pans, for experience has shown that even as early as August, nitroglycerin explosives are liable to freeze. Had such warming pans been provided the accident could not have happened. It is recommended that action should be taken by the police to prevent the issue of certificates to persons who are not in possession of proper warming pans.—B. J. S.

Xyloidins. C. Haeussermann. Z. ges Schiess- u. Sprengstoffwesen, 1906, **1**, 39. Chem. Centr., 1906, **1**, 1196.

Ten grms. of cotton-wool were treated with 2 kilos. of nitric acid (sp. gr. 1·473) at 10°—12° C.; the honey-like mass produced, was allowed to stand for 24 hours at the ordinary temperature, filtered through gun-cotton, and poured into water. The xyloidin which separated, was washed free from acid and dried. It formed a white powder, with a somewhat greenish tinge, which decomposed at 195° C. with a slight explosion, but when ignited in the air, burned fairly rapidly but quietly. It dissolved gradually in glacial acetic acid, but only swelled in acetone and ethyl acetate. The product obtained by treating it with sodium hydrosulphide or ammonium hydrosulphide, dissolved whilst moist almost completely in a 10 per cent. solution of sodium hydroxide, but could be reprecipitated from the solution by acids, salts and alcohol; it also exhibited the other characteristic properties of acid-cellulose (see this J., 1899, 940). The product obtained by denitrating a xyloidin richer in nitrogen, prepared by precipitating with water a clear solution of gun-cotton in 40 times its weight of nitric acid (sp. gr. 1·5) was also found to be acid-cellulose. Collodion-cotton and gun-cotton dissolve in nitric acid of sp. gr. 1·473 at the ordinary temperature, but only very slowly and not completely.—A. S.

Japanese powder and explosives. A. Saposhnikow. Z. ges. Schiess- u. Sprengstoffwesen, 1906, **1**, 69—70. Chem. Centr., 1906, **1**, 1196.

The Japanese smokeless powder for field-guns is stated to consist of a mixture of about 40 per cent. of a collodion-pyroxylin containing 11 per cent. of nitrogen, and 60 per cent. of an insoluble pyroxylin containing 13·4 per cent. of nitrogen. The powder for mountain-guns contains somewhat more of the collodion-pyroxylin. The rifle-powder is an analogous mixture. "Shimose" is identical with ordinary melinite.—A.S.

English Patent.

Explosives; Manufacture of nitroglycerine ——. Deutsche Sprengstoff Act. Ges., Nobelshof, Germany. Eng. Pat. 14,958, July 20, 1905. Under Int. Conv., Dec. 12, 1904.

See Fr Pat. 355,844 of 1905; this J., 1905, 1256.—T.F.B.

UNITED STATES PATENT.

Explosive compound. M. S. Talbot, A. A. Shuter, Durban (Administrator). U.S. Pat. 816,830, April 3, 1906.

SEE Eng. Pat. 26,978 of 1903; this J., 1904, 1112.—T.F.B.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 395.)

APPARATUS, ETC.

Calorimeter; Alcohol ——, for coal testing. W. M. Wallace. Engineering, 1906, **81** 527—528.

THE author substitutes alcohol for water as the expanding liquid in the Carpenter calorimeter, in which the coal is burned in oxygen gas in a small chamber surrounded by water, the expansion of which is used to indicate the heat value of the coal. The advantages of alcohol are: (1) its uniform expansion, which makes it unnecessary to work always at the same temperature; (2) its large coefficient of expansion; (3) its low specific heat. Time may be saved, therefore, by the use of a smaller quantity of coal, it being found that only 0·6 grm. of Welsh coal gave a rise in the tube of more than 30 ins. Instead of correcting for radiation by allowing the apparatus to cool during a period of time equal to that of combustion, a more accurate method is recommended. The rate of radiation per minute is taken before combustion, and with the oxygen flowing. During combustion the alcohol rises rapidly, but towards the end this changes suddenly to a slow crawl. The time is noted at this change, and one-minute readings are taken until the maximum is reached, and for 10 minutes afterwards, with the oxygen still flowing. The mean of the extreme rates of cooling is then used to correct the temperature after the rapid rise, and the true maximum temperature is determined by adding the highest rate of cooling successively to the subsequent readings.

A tube is fixed to the apparatus for collecting the gaseous products of combustion for measurement and analysis, and it is claimed that with this instrument a determination of calorific value, ash, water, carbon, and hydrogen, can be made in half an hour.—F. SODN.

INORGANIC—QUALITATIVE.

Acids; Detection of some ——. [*Boric acid in milk.*] V. Castellana. Gaz. chim. ital., 1906, **36**, 106—108.

MOST of the reactions for the detection of boric acid depend upon the green coloration of the flame, but such reactions are not reliable in presence of copper or halogen compounds. The author recommends carrying out the test in the following manner:—A mixture of the substance under examination, with excess of potassium-ethyl sulphate, is heated in a test-tube, and the vapour ignited. Organic substances, such as milk, are incinerated, the ash ignited with potassium nitrate, and then tested in the manner described. The test permits of the detection of 0·5 mgrm. of boric acid, it is stated.

If formic, acetic, butyric, valeric, pelargonic, oxalic, benzoic, salicylic, or cinnamic acids, or their salts, or β-naphthol be heated with potassium-ethyl sulphate, they can be identified by the characteristic odour of the esters produced. By using potassium-methyl sulphate in place of potassium-ethyl sulphate, anthranilic acid can be detected in a similar manner.—A. S.

INORGANIC—QUANTITATIVE.

Electrolysis; Analytical separation of metals by ——. A. Hollard. Bull. Soc. d'Encourag., Revue de Metall., 1906, **3**, 78—85.

THE problem of separating and successively depositing two metals by alteration of potential difference in the electrolytic cell, is in but few cases a directly soluble one; in the case of many metals the polarisation-pressure is lower than that of hydrogen, and they can only be deposited concurrently with the liberation of hydrogen. Two methods may allow the attainment of the object: 1. The conversion of one metal into a compound with complex ions, *e.g.*, arsenic into an arsenate, iron into a ferrocyanide, &c.; 2. The prevention of the evolution of gas at cathode and anode, *e.g.*, addition of a salt such as magnesium sulphate, which forms complex ions containing hydrogen, and thus raises the potential, requisite to evolve hydrogen at the cathode; also addition of sulphurous acid in the anode cell, to absorb anodic oxygen; use of a cathode coated with tin, cadmium, or lead.—J. T. D.

Chloric acid; Preparation of pure ——, and its application as an oxidising agent. V. Bernard. VII., page 426.

ORGANIC—QUALITATIVE.

Phenyldimethylpyrazolone [*Antipyrine*] *and its more important derivatives; Isonitroso-reaction of ——.* F. Sperling. Z. Oesterr. Apoth.-Ver., 1906, **44**, 51—52. Chem. Centr., 1906, **1**, 1118.

ACCORDING to the German Pharmacopœia 2 c.c. of an aqueous solution (1:100) of antipyrine are coloured green by two drops of fuming nitric acid, whilst after heating to boiling and adding more nitric acid, a red coloration is produced. The author finds that sometimes instead of the red colour with excess of hot nitric acid, a brownish tint is produced, owing to secondary reactions, and he therefore recommends the following test. 2—3 c.c. of the aqueous solution (1:100) of antipyrine are treated with two drops of fuming nitric acid, and after the green colour has appeared, about 5 c.c. of concentrated sulphuric acid are introduced so as to form a lower layer. A cherry-red colour forms at the zone of contact, and on agitation, spreads throughout the whole of the liquid. The reaction is characteristic of antipyrine and its derivatives, with the exception of aminopyrine. The behaviour of different compounds in this test are shown in the following table.

	2 c.c. of a solution of strength.	Addition of fuming nitric acid causes	Addition of concentrated sulphuric acid causes
Salicylic acid	1:500	—	golden-yellow coloration.
Quinine sulphate	1:100	—	" " "
Quinine hydrochloride	1:200	—	" " "
Cocaine hydrochloride	1:100	—	solution remains colourless.
Codeine hydrochloride	1:100	—	orange-yellow coloration.
Phenol	1:100	yellow coloration	reddish-brown coloration.*
Resorcinol	1:100	yellowish-brown coloration	" " " †
Antipyrine	1:100	green coloration	cherry-red ring.
Antipyrine salicylate	1:200	"	" " "
Migranine (antipyrine-caffeine citrate)	1:100	"	" " "
Pyramidone (dimethylaminoantipyrine)	1:100	violet coloration	yellow coloration.
Tussol (antipyrine mandelate)	1:100	green coloration	cherry-red ring.

* Turbidity. † Vigorous evolution of gas. —A. S.

Pinene and camphene; Action of mercuric acetate solution on ——. [Detection of camphene in essential oils.] L. Balbiano. XX., page 442.

ORGANIC—QUANTITATIVE.

Nitrotoluene; Detection and determination of —— in nitrobenzene, and of toluene in benzene. P. N. Raikow and F. E. Uerkewitsch. Chem.-Zeit. 1906, **30**, 205—296.

When nitrotoluene is treated with powdered potassium hydroxide, a brown coloration is developed. Nitrobenzene gives a similar reaction, although decidedly weaker in intensity. Powdered sodium hydroxide does not react with nitrobenzene in the cold; it, however, forms a yellowish-brown compound with nitrotoluene, thus rendering it possible to detect with ease the presence of the latter in nitrobenzene. The reaction between sodium hydroxide and nitrotoluene is intensified, when petroleum spirit is used as solvent, in which case it is possible to recognise 0·0025 mgrm. in 1 c.c. of the solution. In order to detect toluene in benzene, the latter is converted into the nitro compound and examined for nitrotoluene by means of sodium hydroxide. Commercial benzenes purified for use in analysis were found to contain as much as 5 per cent. of toluene, which it was not possible to completely remove even by fractional recrystallisation. To obtain pure benzene it is recommended to subject the commercial article to partial nitration. Nitrobenzene specially purified for analysis was always found to contain nitrotoluene. For the quantitative determination of nitrotoluene in nitrobenzene it is suggested to compare the coloration yielded by sodium hydroxide with that developed by the latter in nitrobenzene containing known quantities of nitrotoluene.—D. B.

Sugar mixtures; Analysis of ——. C. A. Browne, jun. J. Amer. Chem. Soc., 1906, **28**, 439—453.

The cupric-reducing power of any sugar would be constant for all concentrations if the quantity of copper remaining in solution could be maintained constant. The variation in the copper equivalent for every small increment in the weight of sugar is due to the removal of copper from solution, and can, therefore, be calculated as a function of differences determined experimentally, the tables being constructed from the expression so obtained. Consequently, the ratio of the weights of two sugars which reduce the same amount of copper is a constant at all concentrations. Thus, if the ratio of the reducing power of any sugar to that of dextrose be determined by any given method, *e.g.*, Allihn's method, the results can be calculated from one set of tables, *i.e.*, the dextrose table. The dextrose equivalent of a mixture of reducing sugars is equal to the sum of the dextrose equivalents of the components.

If x = percentage of component A with a dextrose ratio of a, and if y = percentage of component B with a dextrose ratio of b, then $ax+by=$ R = percentage of total reducing sugars as dextrose. Similarly, the polarisation of a mixture of sugars is equal to the sum of the polarisations of the components, and if all polarisations are determined on the Ventzke scale, using 26·048 grms. per 100 c.c. and a 200 mm. tube, the polarisation due to any component is equal to its percentage multiplied by a polarisation factor found by dividing the specific rotatory power of the sugar by that of sucrose (+66·5°). Then, if a' = polarisation factor of component A, and β = polarisation factor of B, and if P = polarisation (Ventzke) of the mixture, $a'x+\beta y=$ P. Hence

$$x=\frac{b\mathrm{P}-\beta\mathrm{R}}{a'b-a\beta} \text{ and } y=\frac{\mathrm{R}-ax}{b}.$$

Levulose and dextrose.—Dextrose ratio of levulose = 0·915; polarisation factors, dextrose = 0·793, levulose at 20° C. = —1·356. The variations of the rotatory power of levulose with concentration may be neglected, but corrected values must be used for the polarisation factor when the temperature is above or below 20° C. The dextrose ratio of invert sugar is 0·958, so that the dextrose equivalent of inverted sucrose is almost exactly equal to the sucrose.

Dextrose and galactose.—Dextrose ratio of galactose = 0·898; polarisation factor of galactose at 20° C. = 1·21. This factor must be corrected for variations in temperature. Owing to the slight difference between the rotatory powers of dextrose and galactose, the inherent error is rather high.

Levulose and galactose.—Temperature corrections are necessary for the polarisation factors of both sugars.

Levulose and arabinose.—Dextrose ratio of arabinose = 1·032; polarisation factor of arabinose at 20° C. = 1·571. Only the levulose factor need be corrected for temperature.

Xylose and arabinose.—Dextrose ratio of xylose = 0·983; polarisation factor of xylose = 0·283. No temperature correction necessary.

Dextrose, levulose and sucrose.—The polarisation of the mixture is S + 0·793D — 1·356 L = P_{20}°. Then if S = the percentage of sucrose according to Clerget, $L_{20}^{\circ}=\frac{0\cdot793\,R+S-P}{2\cdot08}$ and D = R — 0·915 L.

There are two sources of error which require correction:

(*a*) *Reducing action of sucrose.*—This is proportional to the concentration of sucrose and to the amount of copper remaining unreduced. It is corrected as follows:—The amount of sucrose in the 25 c.c. of solution taken for Allihn's method is divided by the mgrms. of dextrose equivalent found +40, and the quotient is subtracted from the dextrose equivalent.

(*b*) *The change in rotation of levulose in presence of acid.*—This depends on the quantity of levulose present and on the concentration of the acid in the sugar solution, the Clerget value for sucrose being too high when levulose is present. With 10 c.c. of fuming hydrochloric acid (sp. gr. 1·18) and 100 c.c. of sugar solution, the percentage of sucrose (Clerget) must be reduced by 0·036 for every 1 per cent. of levulose found.—J. F. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 395.)

Metallic films produced by cathodic disintegration; Dichroism, double refraction, and conductivity of ——. C. Mauram. Comptes rend., 1906, **142**, 870—872.

Films were deposited on glass plates placed tangentially to a cylinder of which the circular cathode formed the end. These films showed dichroism and double refraction; their electric conductivity varied with the direction, its maximum and minimum values coinciding respectively with the directions of the luminous vibrations most and least absorbed, these being also the directions of the principal sections as determined from the double refraction. Bismuth showed these properties most strongly of all the metals which were tried. Similar results were obtained when the glass plate was parallel to the cathode; and discharge took place through a strong magnetic field, the lines of force of which were parallel to the cathode and the glass plate; in this case the effects were shown most strongly by nickel.—J. T. D.

Osmosis and osmotic pressure; Nature of the process of ——, with observations concerning dialysis. L. Kahlenberg. Trans. Wisconsin Acad. Sciences, Arts and Letters, 1906, **15**, 209—272.

The author first describes experiments in which layers of chloroform and ether were separated by a layer of water, and shows that in such a case water acts as a semi-permeable septum, allowing ether to pass through to the chloroform, but being almost impermeable for the latter. The results obtained in these experiments and of many others with solid membranes show that whether osmosis will take place in a given case or not, depends upon the specific nature of the septum and of the liquids that bathe it; and if osmosis does occur, these factors also determine the direction of the main current and the magnitude of the pressure developed. The motive force in osmotic processes lies in the specific attractions or affinities between the liquids used, and also between the latter and the septum employed. For example, if a

rubber membrane be employed, the rubber must be capable of dissolving or absorbing one of the liquids bathing it, and, further, the other liquid must be capable of dissolving, or have an affinity for, the liquid absorbed by the rubber. If a solution of cane sugar and pure water be separated by a rubber membrane, no change takes place. With a solution of sodium chloride and toluene, the rubber swells and absorbs toluene, but no osmosis takes place, the brine being incapable of extracting toluene from the swelled rubber. If the two liquids be alcohol and water however, osmosis takes place, the main current being from the alcohol to the water; in this case the alcohol is taken up by the rubber and extracted from the latter by the water. It becomes possible, therefore, by considering the affinity between the two liquids and between these and the septum or membrane, to predict whether osmosis will take place and if it does, what the direction of the main current will be. In osmotic processes there is always a current in both directions; when a septum is termed "semi-permeable," what is meant is that the main current is so much stronger than the other that the latter becomes negligible. Vulcanised caoutchouc acts as "a semi-permeable membrane when it separates pyridine solutions of silver nitrate, lithium chloride and cane sugar from the pure solvent. To obtain accurate measurements of osmotic pressure it is necessary to well stir the contents of the osmotic cell throughout the determination, and the author has devised an apparatus for this purpose. Results obtained in this way show that the gas laws do not hold in osmotic processes. The conclusions arrived at with respect to osmosis apply also to dialysis and the passage of a substance through a membrane is quite independent of whether it is a crystalloid or a colloid. For example, if cane sugar and copper oleate be dissolved together in pyridine and the solution separated from pure pyridine by means of a vulcanised caoutchouc membrane, the copper oleate (colloid) passes through the septum and the cane sugar (crystalloid) remains behind. Also, if the copper oleate be replaced by camphor (a crystalloid), this also passes through, leaving the cane sugar behind. Indeed, in general, any substance which is soluble in both hydrocarbons (caoutchouc) and in pyridine may be separated from cane sugar by dialysis, when the pyridine solution of it and the sugar is separated from pure pyridine by a caoutchouc septum. Other analogous separations with different solvents and membranes may also be effected.—A. S.

Osmosis: Gaseous ——, through a colloidal membrane. J. Amar. Comptes rend., 1906, **142**, 872—874.

Experiments with a rubber tobacco pouch, thoroughly dried, showed that when it was exposed to dry carbon dioxide gas on the inside, the amount of gas absorbed in half an hour was inappreciable as the pressure was raised from the atmospheric pressure to an excess of 10 mm. of petrol-column, then rose rapidly till an excess of 16 mm. was reached, and more slowly up to an excess of 32 mm., the limit of the experiment. A similar membrane exposed on both surfaces to carbon dioxide at a pressure of 40 mm. of petrol-column above the atmosphere, then exposed to air, retained 30·5 mgrms. of carbon dioxide [area of membrane not given]. When the apparatus was arranged so that either surface could be exposed to the gas, and the gas was introduced below the surface, the inner surface was impermeable, while the outer surface absorbed in 45 minutes 1·2—1·4 mgrms.; when the gas was introduced above the surface the inner surface absorbed 1·6—2·5, the outer 4—6 mgrms. in 45 minutes. The nature of the surface thus plays a part in gaseous osmosis, which takes place according neither to the laws of Graham and Bunsen, nor the theories of Stefan and O. Meyer.—J. T. D.

Trade Report.

Spanish Chemical Trade in 1905.

Oil and Col. J., April 21, 1906.

The following particulars are taken from a recent return: Imports:—Alkali carbonates, 15,407,594 kilos., 172,560*l.*; artificial colours, 680,324 kilos., 217,720*l.*; dye extracts, 2,376,473 kilos., 99,800*l.*; indigo and cochineal, 135,438 kilos., 59,600*l.*; raw petroleum, 28,512,121 kilos., 228,080*l.*; oleaginous seeds, 39,536,321 kilos., 743,280*l.*; sulphates of potash and ammonia, 199,166,268 kilos., 1,593,320*l.*; tar, pitch and asphalt, &c., 25,037,366 kilos., 78,880*l.*; wax, 2,301,754 kilos., 158,480*l.* Exports:—Olive oil, 34,377,121 kilos., 1,375,080*l.*; mercury, 1,341,290 kilos., 295,000*l.*; salt, 358,873,232 kilos., 143,500*l.*; common soap, 4,750,996 kilos., 98,840*l.* Except mercury, no increase is shown by these exports. Of the imports, sulphates of potash and ammonia have increased, and the chief falling-off occurs in dye extracts.

Italian Trade in 1905.

Oil and Col. J., April 28, 1906.

The following are from the official statistics just issued: Imports:—Indigo, 535,200 kilos., 128,440*l.*; mineral and coal-tar colours, 4,509,900 kilos., 533,160*l.*; gums and resins, 15,192,300 kilos., 187,800*l.*; olive oil, 14,035,900 kilos., 533,360*l.*; cottonseed oil, 11,979,800 kilos., 311,480*l.*; heavy mineral oils, 31,494,300 kilos, 364,320*l.*; petroleum, 66,492,600 kilos., 531,960*l.*; oleaginous seeds, 64,587,400 kilos., 830,840; copper sulphate, 30,683,700 kilos., 638,240*l.*; a notable increase is recorded in all oils except petroleum, but copper sulphate shows a rather heavy falling off. Exports:—Unmacerated sumac 14,751,300 kilos., 88,520*l.*; macerated sumac, 22,520,700 kilos., 144,120*l.*; matches, 3,354,900 kilos., 195,520*l.*; olive oil, 35,475,900 kilos, 1,571,280*l.*; volatile oils and orange essence, 593,015 kilos., 475,040*l.*; mercury, 242,700 kilos., 49,520*l.*; common soap, 3,305,200 kilos., 80,760*l.*; raw and refined sulphur, 381,128,400 kilos., 1,568,120*l.* The only items which have increased are unmacerated sumac and matches.

United States: Trade of —— in 1905.

Oil and Col. J., April 28, 1906.

A summary of the imports and exports of the United States for the twelve months ending December, 1905, compiled by the Department of Commerce and Labour at Washington, supplies the following figures:—Imports: Alizarin and alizarin colours, 6,391,188 lb.; argols or crude tartar, 27,801,725 lb.; crude asphaltum or bitumen 86,798 tons; coal tar colours and dyes, 5,692,072 dols.; cochineal, 83,410 lb.; cutch and gambier, &c., 35,211,452 lb.; glue, 7,066,037 lb.; glycerin, 32,040,460 lb.; grease, 325,867 dols.; gum arabic, 3,383,399 lb.; crude camphor gum, 1,724,499 lb.; copal and kauri gum, 24,760,815 lb.; indigo, 6,397,625 lb.; bleaching powder, 104,919,402 lb.; linseed, 231,639 bushels; whale and fish oil, 856,727; other animal oil, 150,590 galls.; mineral oil, 13,725,720 galls.; olive oil, 1,055,660 galls.; other fixed oils, 5,221,248 dols.; volatile or essential oils, 2,606,327 dols.; paints and colours, 1,570,839 dols.; perfumery, cosmetics, &c., 993,575 dols.; crude phosphate, 56,021 tons; other fertilisers, 4,051,003 dols.; plumbago, 15,568 tons; potassium chlorate, 42,510 lb.; potassium chloride, 214,207,064 lb.; crude saltpetre, 9,911,534 lb.; all other potash, 82,935,632 lb.; shellac, 13,209,883 lb.; fancy, perfumed, and all toilet soap, 1,071,446 lb.; all other soap, 399,797 dols.; caustic soda, 2,245,789 lb.; sodium nitrate, 321,231 tons; "sal soda," 1,943,230 lb.; soda ash, 13,807,749 lb.; other salts of soda, 11,257,629 lb.; sponges, 612,315 dols.; crude sulphur or brimstone, 83,201 tons; ground sumac, 14,537,746 lb.

Exports: Acids, 335,534 dols.; acetate of lime, 70,816,382 lb.; wood alcohol, 891,813 gals.; pot and pearl ashes, 723,932 lb.; beeswax, 107,192 lb.; candles, 7,864,966 lb.; copper sulphate, 19,367,179 lb.; cottonseed, 23,769,164 lb.; dyes and dyestuffs, 457,990

dols.; flaxseed, 1,409,432 bushels; glue, 3,121,881 lb.; grease and all soap stock, 3,998,383 dols.; lampblack, 653,621 dols.; matches, 62,385 dols.; naphthas, including all lighter products, 28,419,930 galls.; corn oil cake, 42,454,947 lb.; cottonseed oil cake, 1,214,667,922 lb.; linseed oil cake, 604,454,483 lb.; corn oil, 3,347,827 galls.; cottonseed oil, 53,368,839 galls.; fish oil, 800,879 galls.; illuminating oil, 881,450,388 galls.; lard oil, 294,491 galls.; linseed oil, 215,667 galls.; lubricating oil, 113,730,205 galls.; crude mineral oil, 126,185,187 galls.; mineral oil residuum, 70,727,877 galls.; peppermint oil, 54,039 lb.; other essential oils, 326,881 dols.; other vegetable oil, 188,945 dols.; other animal oil, 232,823 galls.; whale oil, 10,224; "oleo oil," 182,342,771 lb.; paints and colours, 3,506,486 dols.; paraffin wax, 160,835,882 lb.; perfumery and cosmetics, 499,413 dols.; rosin, 2,258,126 lb.; toilet or fancy soap, 1,042,185 dols.; all other soap, 44,110,949 lb.; spermaceti, 82,013 lb.; spirits of turpentine, 15,614,323 galls.; starch, 68,570,460 lb.; tallow, 81,702,816 lb.; tar, 18,692 lb.; turpentine and pitch, 19,809 brls.; varnish, 775,491 galls.; washing powder, 6,308,547 lb.; oxide of zinc, 22,560,625 lb.

New Books.

MINES AND QUARRIES: GENERAL REPORT AND STATISTICS FOR 1904. Part IV. Colonial and Foreign Statistics. [Cd. 2911.] Wyman & Sons, Fetter Lane, E.C. Price 1s. 9d.

THE present report, consisting of 488 foap. pages and index, contains statistics as to persons employed, output, and accidents at mines and quarries in the British Colonies and in foreign countries, together with a summary of similar data with regard to the British Isles.

TURPENTINE INDUSTRY OF THE UNITED STATES. Foreign Off. Mis. Ser., No. 647. [Cd. 2683.] Price 1½d.

8vo pamphlet of 17 pages, containing a description of the methods of extracting turpentine in the United States, and an account of the present state of the industry and export trade.

JOURNAL OF THE

Society of Chemical Industry.

No. 10.—Vol. XXV. SUPPLEMENT. MAY 31, 1906.

HON. TREASURER:—
Samuel Hall, East London Soap Works, Bow, E.

PRESIDENT:—
Dr. Edward Divers, F.R.S.
GENERAL SECRETARY:—
Charles G. Cresswell.

EDITOR:—
Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the society.
French.—1 fr. 25 c. each, to Belin et Cie, 56, Rue des Francs-Bourgeois, Paris (3e).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy. A form of application for this purpose will shortly be issued.

Members are invited to call the attention of the Editor to any errors or omissions which they may have noticed in the Annual Indexes, 1896—1905, as soon as possible, in order that they may be put right in the Decennial Index.

List of Members Elected.

May 23rd, 1906.

Bushy, Fred. E., Arnold Print Works, North Adams, Mass., U.S.A., Chemist.

Chittenden, George, The Francis Frost Co., Ltd., Toronto, Canada, Chemist.

Cowan, Geo. D., Bridge House, Bridge Road, Millwall, E., Manager, De-silverising Works.

Drew, W. Newton, Ramcliffe, Ecclesfield, near Sheffield, Chemical Manufacturer.

Furlong, John R., 182, Commercial Road, London, E., Research Chemist.

Girtin, Thomas, H. L. Raphael's Refinery, Thomas Street, Burdett Road, London, E., Bullion Refiner,

Henning, C. I. B., P.O. Box 42, Santa Cruz, Cal., U.S.A., Chemist.

Jardine, Samuel, c/o Dallyn, Jardine & Co., 23 Scott Street, Toronto, Canada, Chemical Merchant.

Keymer, S. H., 149, 12th Street, Long Island City, N.Y., U.S.A., Superintendent.

Larson, Axel, 85, Gracechurch Street, London, E.C., Mining Engineer.

Monier-Williams, G. W., The Lammas, Esher, Surrey

Pafiazzoni, Charles F., Emporium, Pa., U.S.A., Chemist.

Payne, J. H., c/o Eastman Kodak Co., Kodak Park Works, Rochester, N.Y., U.S.A., Chemical Engineer.

Reed, Wm., Bridge House, Bridge Road, Millwall, E., Foreman, De-silverising Works.

Rossiter, E. C., 4, Park Road, West Smethwick, Birmingham, Chemical Engineer.

Rowell, Herbert W., c/o Messrs. Locke, Lancaster & Co., Ltd., Bridge Road, Limehouse, London, E., Analytical Chemist.

Schmidt, J., Cross Street, Burton-on-Trent, Works Manager.

Schwerin, Lorenz R., c/o Casein Co. of America, Bainbridge, N.Y., U.S.A., Vice-President, Casein Co.

Smith, E. A. Cappelen, c/o Baltimore Copper Smelting and Rolling Co., Baltimore, Md., U.S.A., Metallurgical Engineer.

Tanaka, S., No. 4, Uratakashimacho Nichome, Yokohama, Japan, Chief Chemical Engineer (Electric Wire Works).

Wickens, A. M., 280, Berkeley Street, Toronto, Canada, Mechanical Engineer.

Wilkinson, John E., 71, Lombard Street, Toronto, Canada, Gold and Silver Refiner.

Wood, E. Escott, Hurricane House, Brymbo, near Wrexham, North Wales, Chemist and Metallurgist.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the journal depends.

Allen, R. L.; (Journals) c/o Brunner Mond and Co., Ltd., and (communications) Hillside, Sandbach, Cheshire.

Aykroyd, H. E., l/o Apperley Bridge, Scaitcliffe, Queen's Road, Ilkley, *via* Leeds

Baxter, John G., l/o Cliffe; 143, Milton Road, Gravesend, Kent.

Bement, A., l/o Dearborn Street; American Trust Building, Chicago, Ill., U.S.A.

Bennett, Arnold; Montreal Steel Works, Ltd., Point (not Port) Saint Charles, Montreal, Canada.

Bradburn, J. A., l/o East Genesee Street; 503, Willis Avenue, Syracuse, N.Y., U.S.A.

Cofman-Nicoresti, J., l/o Bloomsbury; 24, St. Gabriel's Road, Cricklewood, N.W.

Crowther, W. M.; Journals to Chemical Works, Gomersal, near Leeds.

Curphey, W. S., l/o Lenzie; 7, Derby Crescent, Kelvinside, Glasgow.

Duckworth, Wm. H., l/o Sylvan Avenue; Springfield Lodge, Sale, Cheshire

Emery, A. L., l/o San Francisco; Rooms 28-30, 1104 Broadway, Oakland, Cal., U.S.A.

Etheridge, Arthur T., l/o Stanford-le-Hope; 85, Hampton Road, Birchfield, near Birmingham.

Harvey, H. C., l/o Brooklands; Messrs. Fothergill and Harvey, Ltd., 31, Cooper Street, Manchester.

Hawkins, Henry, l/o Todmorden; Moyola Villa, Lansdown, Limerick, Ireland.

Hodgson, T. R., l/o Canonbury Square; 21, Framfield Road, Highbury, N.

Ibbotson, E. C., l/o Sheffield; Gysinge, Sweden.

Iddings, R. P., l/o Wyman Street; Arlington Mills, Lawrence, Mass., U.S.A.

Knapp, S. A., l/o Nevada; Crocker Building, San Francisco, Cal., U.S.A.

Leuthardt-Thornton, P.; all communications to 14, Steele's Road, Hampstead, N.W.

Lucas, A., l/o Cairo; Survey Dept., Giza, Egypt.

Moignot, Réné, l/o Hotel des Arcades; 8, Rue Thierry Martens, Alost, Belgium.

Noake, Frank, l/o Dunstall Park; 20, Craddock Street, Wolverhampton.

Pickard, Glenn H., l/o Brooklyn; c/o The Spencer Kellogg Co., Buffalo, N.Y., U.S.A.

Pinnock, H. T.; Journals to Beacon House, Dudley Port, Staffordshire.

Prideaux, E. B. R., l/o Beckenham; (Journals) Heriot Watt College, and (communications) 62, Queen Street, Edinburgh, Research Chemist.

Reid, Andrew, l/o Minard Road; 37, Mount Stuart Street, Shawlands, Glasgow.

Ridge, H. M.; all communications c/o Central Zinc Co., Ltd., Finsbury House, Blomfield Street, London, E.C.

Schüpphaus, Dr. Robt. C., l/o Broadway; 175, Pearl Street, New York City, U.S.A.

Smith, Jas. F., l/o Halifax; 131, Seamer Road, Scarborough.

Swindells, Seth, l/o Lawton; The Laurels, Scholar Green, Stoke-on-Trent.

Taylor, Jas. M., l/o Sefton Park; Tynevale, Groes Road, Cressington, Liverpool.

Taylor, Wm. H., l/o Upper Clapton; 20, Baleaskie Road, Eltham Park, Kent.

Unglaub, Oscar, l/o Manchester; 1808, Edgmont Avenue, Chester, Pa., U.S.A.

Watt, H. E., l/o Birmingham; retain Journals.

Weldon, L. E., l/o Central Avenue; 154, Egypt Road, New Basford, Nottingham.

Wrampelmeier, T. J., l/o New York; San Francisco, Cal., U.S.A.

Young, A. C., l/o Ladywell; 17, Vicar's Hill, Lewisham, S.E.

Change of Address Required.

Healey, A. E.; l/o Willesden Junction, N.W.

Member Omitted from List.

1905. White, Clarence B., c/o Herringbone Metal Lath Co., 156, Fifth Avenue, New York City, U.S.A., Chemist.

Deaths.

Bateson, Percy, Cuckoo Lane, Gateacre, Liverpool. May 12.

Muir, Jas. P., 233, Camden Road, London, N. Jan. 15.

Squire, Dr. Wm. Stevens, at Taormina, Sicily. May 13.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 10,015. Wegelin and Geilenkirchen. Method of and apparatus for raising liquids.* April 30.

" 10,055. Collier. Centrifugal separators. April 30.

" 10,162. Petitpierre. Homogenising breaker to emulsify, pulverise and homogenise liquids and semi-liquids, and break fatty or albuminous cellules and nuclei.* May 1.

[A.] 10,261. Wright. *See under* III.
„ 10,313. Röck. Smokeless furnace.* May 2.
„ 10,814. Graham. Apparatus for condensing and purifying gases especially applicable to the manufacture of sulphuric and other acids. May 8.
„ 10,852. Forsbach. Muffle furnaces.* May 9.
„ 10,948. Martini and Huneke. *See under* III.
[C.S.] 9011 (1905). Spooner (Aktiebolaget Separator). Centrifugal separators for liquids. May 9.
„ 9417 (1903). Aktiebolaget Separator. Centrifugal separators for liquids. May 9.
„ 9549 (1905). Kestner. Process for laying smoke from funnels, chimneys, &c. May 9.
„ 14,572 (1905). De Laval. Process for obtaining a violent chemical reaction between materials. May 16.
„ 15,371 (1905). Covell. Distilling apparatus. May 16.
„ 16,477 (1905). Sugg. Apparatus for compressing gases. May 16.
„ 19,913 (1905). Ayres. Separating machines. May 9.
„ 20,752 (1905). Ostertag. Drying furnaces for coal, &c., with superposed shelves or hearths. May 16.
„ 20,865 (1905). Trent. Agitating and mixing apparatus. May 16.
„ 26,668 (1905). Girod. Apparatus for raising liquids by direct fluid pressure. May 9.
„ 26,724 (1905). Lorrain (American Process Co.). Continuous screw presses for drying and similar operations. May 16.
„ 2419 (1906). Critien. *See under* XVIII*B*.
„ 2755 (1906). Ruttkamp. Mixing machines. May 16.
„ 4907 (1906). Thompson. *See under* XVIII*B*.
„ 5859 (1906). De Laval and Fagerström. Centrifugal liquid separators. May 9.

II.—FUEL, GAS, AND LIGHT.

[A.] 10,024. Laurent. Manufacture of arc light carbons. April 30.
„ 10,106. Forbes. Calcium carbide preparations. April 30.
„ 10,158. Hartenstein. Manufacture of carbide.* May 1.
„ 10,159. Hartenstein. Carbide and its production.* May 1.
„ 10,160. Hartenstein. Production of carbide.* May 1.
„ 10,357. Ruffert. Manufacture of incandescent bodies for use in connection with incandescent lighting.* May 3.
„ 10,412. Koppers. Gas furnace installation.* May 3.
„ 10,751. Tolson. Gas producing apparatus used with gas engines. May 8.
„ 10,835. Lynde. Production of gas from petrol and other hydrocarbons. May 9.
„ 10,887. Tully. Manufacture of carburetted water gas. May 9.
„ 11,004. Hersey. Gas washer scrubbers. May 10.
„ 11,077. Fillunger. *See under* VII.
„ 11,099. Browne. Manufacture of gas from coal, &c. May 11.
„ 11,133. Burschell. Process of removing sulphide of hydrogen from gases.* May 12.
[C.S.] 8891 (1905). Frenot. Filaments for electric incandescent lamps. May 9.
„ 9588 (1905). Shedlock. Manufacture of coke. May 16.
[C.S.] 9705 (1905). Cousen. Vaporising and carburetting apparatus. May 9.
„ 11,956 (1905). Woodall and Duckham. Vertical retorts for the carbonisation of coal. May 16.
„ 12,289 (1905). Woodall and Duckham. Vertical retorts for the carbonisation of coal. May 16.
„ 13,914 (1905). Connell, Haldane and Thomson. *See under* XVII.

Official Notice.

ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Manchester, on Wednesday, July 11th next and following days. A programme and request form accompany this issue.

In accordance with the provisions of Rule 18 of the By-Laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council (see Journal for April 30th, p. 341) will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Eustace Carey has been nominated to the office of President under Rule 8; Dr. E. G. Love, Mr. A. Gordon Salamon, and Mr. Chas. Wightman have been nominated Vice-Presidents under Rule 8; and Dr. E. Divers, F.R.S., has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Members are hereby invited to nominate fit and proper persons to fill four vacancies among the ordinary members of the Council. Forms for this purpose can be obtained, on application, from the General Secretary, or from the Hon. Local Secretaries.

Extract from Rule 18:—"No such nomination shall be valid unless it be signed by at least ten members of the Society who are not in arrear with their subscriptions, nor unless it be received by the General Secretary, at the Society's office, at least one month before the date of the Annual General Meeting, at which the election to which it refers takes place. Nor shall any such nomination be valid if the person nominated be ineligible for election under Rules 12 or 15. No member shall sign more than one nomination form."

ALTERATION OF BY-LAWS.

With a view to facilitate the voting of members residing abroad, notice is hereby given, in accordance with Rule 35 of the By-laws, that the Council will propose to the forthcoming Annual General Meeting the amendment of the Society's By-laws as follows:—

1. Rule 18. (*a*) That the words "At least two months before the date of each Annual General Meeting," in the first and second lines thereof, be replaced by the words, "In the second issue of the Society's Journal for the month of April in each year."

(*b*) That the words "date of that meeting," in the fourth line thereof, be replaced by the words "Annual Meeting next ensuing."

(*c*) That the words "At least one month before the date of;" in the sixth line from the end thereof, be replaced by the words "not later than the last day of May prior to."

(*d*) That the words "to the election to take place at which it refers" in the fifth line from the end thereof, be replaced by the words "at which the election to which the nomination refers is to take place."

2. Rule 19.—That the words "at least five days before the commencement of the said meeting," in the two last lines thereof, be replaced by the words, "in the second issue of the Society's Journal for the month of May."

Deaths.

Bateson, Percy, Cuckoo Lane, Gateacre, Liverpool. May 12.

Muir. Jas. P., 233, Camden Road, London, N. Jan. 15.

Squire, Dr. Wm. Stevens, at Taormina, Sicily. May 13.

Birmingham Section.

Meeting held at Birmingham on Thursday, March 25th, 1906.

PROF. FRANKLAND IN THE CHAIR.

A COMPARISON OF ENGLISH AND AMERICAN METHODS IN THE REFINING AND MANUFACTURE OF COPPER.

BY FRANK PLATTEN.

The visit of the Society of Chemical Industry to the United States in the autumn of 1904, afforded me a long wished for opportunity of seeing the metallurgical works of that country. It is astonishing to contrast the willingness with which visitors are shown over these vast establishments in America, with the secrecy observed in this country—it must be due, to some extent, to the knowledge that the high tariff wall shuts out all fear of competition from this country in their market, and there appears to be no immediate prospect of any alteration in these conditions.

Tracing the course of the metal from ore to finished ingot, copper occurs for the most part as sulphide—is usually smelted in blast furnaces with or without a preliminary calcining and the sulphide, technically known as matte, is obtained, the gangue of the ore being got rid of in the form of slag.

A later form of blast furnace treatment is known as pyritic smelting—in this method, by means of a heated blast, the sulphur and iron present in the ore are utilised as fuel, and coke is almost, if not entirely, dispensed with—this process is a most important development, enabling ores occurring in out of the way districts far removed from a coalfield to be treated on the spot, which would otherwise not be dealt with owing to the cost of carriage.

The copper smelting industry some years ago borrowed from the steel trade the Bessemer idea, and now the sulphide of copper, or matte, is blown in converters to pig copper, the sulphur being consumed by the hot air blast—behaving very much like the silicon in cast iron under similar conditions. The converter pig now contains about 99 per cent. copper, with generally some silver and gold, and is cast into anodes and sent to the electro depositing plants—this process separates the precious metals, and the electro deposited copper is then refined in reverberatory furnaces and cast into wire bars, cakes and ingots.

The 75-ton copper refinery furnace is no myth—I have seen a refinery containing 10 such furnaces with the greater part of them in operation, and concede all that has been said in their praise—but when one considers fully the trade conditions obtaining in the two countries, it will be seen that, desirable as many American methods are, they are frequently inapplicable in English works.

The term "refine," as far as American practice is concerned, is a misnomer—you will find on referring to any standard dictionary the word means "to purify or separate from extraneous matter." The copper charged to American refineries being electro deposited is already as pure as it can be made, and all they have to do is to change the shape of the article from cathode plate to the form required, and there we come to the first point in the differing conditions.

The cathode plates are piled in the furnace, the doors closed, and the fire urged, and, when all is melted, practically a bath of pure copper is obtained containing at the worst a trace of sulphur taken up from the coal, and oxygen which is removed by the usual method known as poling, that is, plunging beneath the surface of the molten copper the stem of a tree; the reducing gases from which remove the oxygen from the copper in just the proportion required. The conditions are ideal for handling large quantities, and I must say, in justice to our American

cousins, that they have not been slow to avail themselves of their opportunity; their works are magnificently equipped and run with machine-like precision, to see one of these huge furnaces charged by means of a system of air lifts is a revelation, and their capacity has steadily grown until the present enormous tonnage is by no means uncommon, and attempts are shortly to be made to deal with charges of 100 tons. Where the development in size of copper refining furnaces will stop, it is hard to say, but I incline to agree with several American metallurgists, that the limit has been reached; the enormous weight of the charge and the corrosive action on the furnace walls at one stage in the refining process constitute important factors, also the length of time required to empty the furnace, during which a particular state of oxidation termed "pitch" has to be maintained, must be taken into account.

You have no doubt noticed in the English market quotations for copper, the word "standard." What an American refiner would make of 75 tons of this material in one of his furnaces cannot be imagined. Roughly, the composition and necessary treatment is as follows:—The copper percentage is 96, the balance being chiefly sulphur, iron and arsenic.

In dealing with a 15-ton charge of this material, the sulphur is the chief difficulty encountered; on melting down, some of this escapes by oxidation, but the melted bath still contains sufficient sulphur to keep the metal in a constant state of ebullition, due to the escape of sulphur dioxide from the gradual oxidation caused by the atmospheric oxygen which is now allowed to play over the surface. Treating material with 1 per cent. sulphur, a percentage that is often exceeded in standard copper, this ebullition continues frequently for two or three hours, and at the end of this period, sulphur still remains to a sufficient extent to require several hours of what is known as rabbling—that is, agitation of the bath by means of an iron tool, a form of hand labour for which no mechanical substitute has yet been invented. When the last traces of sulphur are removed, the method proceeds on the same lines as in the States, with this great difference that the treatment of this small quantity has occupied 24 hours.

It will be seen even from this short description, that so long as English refiners have to depend on standard copper and Chili bars, which are approximately of the same composition as standard, a daily charge of 15 tons is about the maximum that can be dealt with. But even supposing the days of standard copper should pass and Chili bars cease to exist and English refiners find themselves in a position to deal with electro-deposited copper in their furnaces, another obstacle has to be encountered, and this brings me to the second, and, I fear, an insuperable difficulty, one which handicaps many of our industries, and which no doubt you have noticed is periodically ventilated in the press. I refer to the lack of standardisation in specifications which confronts many of the manufacturers of this country.

It is said that if a buyer requires a locomotive from, say, the Baldwin works he has to take one of the standard patterns or nothing. This is far from being the case with English locomotive builders.

I believe the tests and inspection governing this industry are of the most exacting description, but I can only speak as regards the manufacture of the firebox, which, as you are aware, is made of copper. It is difficult to see how copper refiners are ever to use large modern furnaces in the face of the variation in specifications relating to the composition of copper. I will not now go into the question of what quality of copper is best suited for firebox work, but will give as an instance the proportions of arsenic that are commonly asked for. One engineer will require a percentage of 0·35 to 0·55, while another limits it to 0·15 per cent., while specifications reading "arsenic must not exceed 2 per cent.," "arsenic must be present in the proportion of 0·25 to 0·4 per cent." are not unusual. I can offer no explanation of this diversity of opinion, but no doubt the questions of quality of water and nature of fuel are largely concerned.

In addition to this element, limits are in some cases placed on the presence of nickel, lead, bismuth and oxygen, and, as an extreme case, I may mention that "best selected copper," which is one of the purest forms of the metal, is sometimes required.

When it is also borne in mind that the mechanical tests are of even greater variation and the same complexity extends in, perhaps, a lesser degree to the manufacture of tubes, rods, &c., it will be seen at once that large charges cannot be made, bearing in mind the high and fluctuating price of the metal which precludes makers from carrying heavier stocks than absolutely necessary.

Until greater uniformity in this matter is obtained, any considerable increase in the capacity of English refinery furnaces is out of the question, and we must continue to look with envious eyes on these magnificent metallurgical appliances with their low labour costs and regret that English makers are debarred from availing themselves of their use.

It is, perhaps, interesting to note that in no instance are these colossal furnaces heated with producer or other gas, but the waste heat is invariably utilised by erecting water-tube boilers in the flues, and in the works of the Nichols Chemical Co. the steam raised from this source is said to be equivalent to 75 tons of coal per day.

To illustrate further the advantages enjoyed by the American copper industry, I may mention copper telephone wire, such as is supplied to the British Post Office. This wire is required hard-drawn to give a high tensile strength—a course of treatment which naturally deprives the metal of some of its pliability; this particular size, somewhere about 3/32 in. must have a breaking strain of 32 per square inch, and when it is remembered that the same wire in its soft or annealed state breaks at about 14 tons, it will be seen that a large amount of work has been put on the metal. Notwithstanding this, it has to stand a torsion test, that is, twisting thirty times in a length of 3 in.—sufficiently stringent tests; but I am glad to say his Majesty's Post Office can readily obtain wire of this quality from English makers, although its preparation entails the exercise of the very greatest care on the part of the manufacturer.

The American Post Office authorities some time ago imposed similar tests on the American makers, but great difficulty was experienced in complying with them. A very simple way was found of dealing with the matter, and in response to representations from the manufacturers the tests governing tensile strains, torsion, &c., were removed, the American Post Office being content with "hard-drawn wire."

The electro-refining works dealing with copper present no novel features, complete descriptions of most of the plants having appeared in various journals; it is curious, however, to note that at the works of the Nichols Chemical Co., at New York, the series process is exclusively operated. I believe this is the only important refinery working on this principle, the multiple system having preference elsewhere, and yet these are the largest works of their kind producing one-fifth of the world's output of electro-deposited copper.

The low cost of producing the thin anode sheets necessary for working the series process must have contributed largely to the success of the plant. It was at these works that we saw a Bessemer plant at work blowing copper matte up to bars of 99 per cent. purity. As far as I know, this process has made little, if any, headway in this country and yet for rapidity and uniformity in its work it is far ahead of the older reverberatory method. I believe it is urged against it that the loss of precious metals is high, but with the recent improvements in dust and fume-catching apparatus it would seem that this should not be a matter of serious importance.

As regards the metal works where the output of rolled copper and brass reaches enormous totals, I was struck with the great advantages which the American manufacturer enjoyed, unlimited space—for these establishments are never put down very near to a great city where land is likely to be at a premium—combination of interests, so that separate works can be as far as possible concentrated on to the manufacture of one or, at any rate, a small number of articles, thus enabling specialists to be employed in every branch, and last, but not least, huge timber reserves, making it possible to use this as

fuel in annealing furnaces where, from its long, clean, non-sulphurous flame, a very high standard in the way of surface is obtained on all sheet metal.

The amount of delegation in American works is surprising when one considers the multifarious duties usually connected with similar positions in this country, and I attribute much of the success of the works I visited to the way in which the American superintendent divests himself of all routine work and devotes his energies almost exclusively to the study of his processes and methods.

At first sight it seemed to me that the chemical supervision was inadequate—a group of eight works dealing with enormous outputs situated at considerable distances from each other boasted only one laboratory between them. I suppose it would be difficult to find a metal works in this country, with any desire to be up to date, that had not its laboratory, but here again the conditions of trade come in with marked effect. For instance, in American works practically the whole of the copper for brass making is of one uniform quality—pure electro deposited—in fact, one important works admits nothing that is under 99 per cent. conductivity, and a most careful system of electrical tests is maintained to ensure this condition being carried out.

The most minute traces of arsenic and other impurities would lower the conductivity much below this figure; it will therefore be seen how certain is the question of quality in these works. This will appeal to all who are accustomed to the copper used in English metal works. Best selected ingot is the name of the article, and a requisition for a parcel of such material may bring one of a dozen different brands containing a certain amount of various impurities, all of which are liable to exert considerable modifications when alloyed with such metals as zinc, tin, aluminium, &c., and in these days of exact requirements a great deal of careful examination is necessary to deal successfully with such material.

It is obvious then that the need of the chemist is on this account not so great in American metal works although, in my opinion, many of their processes would be more efficiently carried out under his supervision—especially when dealing with by-products, slags from cupolas, &c.

America must always, I feel, reign supreme in the copper industry for the very simple reason that the metal is there. I believe the latest figures show that more than half of the world's production is mined in the States, which, in itself, is a factor of the greatest importance, but when you add to this the restless energy and ability of the people and the thousand and one natural advantages of that great country, one is bound to realise the facts of the situation.

It is, therefore, apparent that America must remain the great centre of progress and development in this industry, and I can advise nothing better for anyone interested in the chemistry and metallurgy of copper than to pay a visit to these great establishments to which I have, I fear, in this short paper done but scant justice.

Discussion.

Mr. A. H. Hiorns asked whether the 75-ton refinery referred to was an ordinary reverberatory or not? With regard to the abundance of copper ore in America as compared with this country, was it not a fact that we have practically no ore in this country, that, no doubt, made a very considerable difference in the methods of working? Another point Mr. Platten referred to was the enormous time taken up in the removal of the last traces of sulphur, amounting to several hours, entirely done by atmospheric air. Were not certain oxidising agents added to the copper bath? To him the method of standards which Mr. Platten referred to was one of the great draw-backs in England. Engineers and others specified absolutely absurd standards, the reason being they did not know sufficiently of the subject. He thought few people absolutely knew the effect of arsenic, or bismuth, or lead, or antimony, or phosphorus on copper, because nobody attempted to make a complete investigation with the pure metal. It could never be known what effect an element had upon another element until that element was used in its pure state, and pure samples of the other substance introduced. One man would say, for instance, what enormous influence antimony had on copper, and we be alarmed by the fact that there should be added, 0·2 per cent. of antimony. If 0·2 per cent. of antimony were present in pure copper, then another 0·2 per cent arsenic added to it, it would actually improve the copper instead of diminishing its malleability. Points like th required publishing, as to the effects of the differ impurities on copper; then all these absurd specificati would not be put forward by engineers.

Mr. Alex. E. Tucker asked if the author ever ca across what was practically a Wellman-Siever furna i.e., a tipping furnace for copper. He very cordi supported his views as to the necessity among engine in this country of standardisation of their specificatic He had had occasion to deal with the matter persona and, as Mr. Hiorns had said, the amount of ignora shown by the people in authority on these matters often lamentable, having regard to the very heavy su at stake. This applied not only to copper for fire-boxes, b but, practically speaking, to a great deal of gene metallurgical work. It was noticeable in the case of si Virgin spelter was contracted for; what virgin spel really was was still a disputable point. He supposed originally meant spelter which was made directly fr the ore, but at the present time there was plenty spelter made from by-products, and which could produced as pure as, and often very much purer th spelter made directly from the ore. This and simi want of uniformity in respect of trade terms and th corresponding chemical purity was a matter which mi properly be dealt with by such a society as ours. If, say, Birmingham Section, as being immediately connected w metallurgy, would deal with the subject, he should exp the London Section would co-operate and bring it bef the George Street engineers and others concerned. was certainly a matter of high importance, not o intrinsically, but also in reference to the Continen and American practices, and he would suggest th something of the sort be taken in hand with a view putting it on a proper working basis.

Mr. W. Rosenhain asked why English copper refin could not use the pure electrolytic copper that was used America. Without having any special knowledge of t copper industry, it appeared to him that if so much ti was occupied by the elimination of sulphur, and t capacity of the plant so greatly diminished thereby, t removal of the sulphur by electrolytic means might preferable.

Mr. Platten, in reply, said he regretted that the pa had been of a rather general nature. He should ha been very glad to have given greater detail in regard the points he had touched upon had it been possit He agreed with Prof. Frankland that the grea abundance of copper in the States would be less lik to lead to improvements in the refining of copper th in this country, where the metal was scarcer. He w referring chiefly to the low labour costs which obtain in the States; they were able to deal with the metal much larger masses in their huge furnaces, at a figu which could not be approached in this country, with t small furnaces. The 75-ton furnaces were reverberato furnaces of the same type as those in use in this countr They differed very slightly from those seen in all Engli works, except that the dimensions were greater in eve particular. The depth of the metal-bath was almo double what was customary in this country, but fro inspection of a great number of furnaces in the Stat he could say that practically their design was the sam As to removing the impurities by means of solid flux such fluxes were certainly used; nitrate of soda wa the most common, but its use was confined to the elim nation of arsenic and antimony. The last traces sulphur must be removed by the process he had me tioned; it was of the utmost importance that that shou be done, otherwise the metal, on being cast, expelled t sulphur in the form of gas, at the moment of solidificatio causing porosity on the surface of the ingot. He could n agree with the strictures which Mr. Hiorns passed upon t

English locomotive engineers in general. The experience of nearly all these engineers was different, because the quality of the water and fuel varied in different parts of the country, and he believed many of the specifications presented to manufacturers were drawn up actually on the working results on the respective railways. Mr. Hiorns suspected that the secrecy on the part of the English refiners was owing to their plant being so very primitive. He could only adhere to what he had said in the paper—it was impossible to enlarge the furnaces to any considerable extent, and thus bring into play the latest mechanical casting appliances, for the reasons he had stated. To elucidate that point, imagine an English manufacturer getting an order for, say, 20 tons of locomotive plates, to a certain specification, with the arsenic or some other element limited to a narrow margin. If he were using a 75-ton furnace, it would be necessary for him to make 75 tons of copper of that particular composition; that might leave him with 55 tons of copper on his hands, and, at the present price of the metal, that would be a serious matter. He was interested in what Mr. Hiorns said with regard to impurities in copper, especially as to the injurious effect of antimony being mitigated by the presence of arsenic, and agreed with him that a study of the impurities in combination was of great importance. A great deal of work had been done on this subject by the late Sir W. Roberts-Austen, and one of the most valuable results published showed that the presence of arsenic in copper could mask the effect of bismuth, which was one of the most difficult impurities with which the copper metallurgist had to deal. He did not think tilting furnaces had been used in the States for copper, but he had for some time thought that with our small furnaces, where the mass of metal was so light that it was impossible to tap, as was done in the States, it was highly likely that experiments made on the lines of the tilting furnace might meet with very great success. Electro-copper was not available for the English furnaces because it commanded a considerable premium over bar copper in England, and the question of its use in refining furnaces was entirely one of prices.

Manchester Section.

Meeting held at Manchester on Friday, April 6th, 1906.

DR. G. H. BAILEY IN THE CHAIR.

THE MECHANICS OF WATER SOFTENING.

BY JOHN J. ROYLE.

The subject of water softening is receiving increased attention in this country amongst industrial concerns. Very rarely does water exist in a sufficiently pure state for manufacturing purposes, and the increasing competition, particularly in the textile trades, is forcing attention to this subject of the purification of natural waters.

The subject of water softening is, first of all, a problem for the chemist, and, secondly, for the engineer who has to provide such mechanical means as will enable the chemist to accomplish what he knows to be necessary to bring about the desired result. It is essentially a case where the two departments of knowledge should come together if the best result is to be accomplished. It may also be laid down as axiomatic that the engineer who can effect what the chemist wants with the simplest, cheapest, and least liable to be deranged, yet efficient apparatus is most likely to succeed commercially.

I propose in this paper to deal with the subject of water softening from the standpoint of the mechanician endeavouring to carry out what is settled as the chemistry of the subject, and after briefly passing in review the more general and well-known devices, with comments on their advantages and disadvantages, pass on to notice some recent improvements which, I think, will be found to carry the subject a step further towards perfection.

I omit all reference in this paper to the use of heat—generally steam—to remove temporary hardness. Not only does it leave the problem unsolved at the most difficult point, *viz.*, the permanent hardness, but it only partially removes the temporary hardness. Nothing short of vigorous boiling by live steam, thus driving off the carbonic acid gas thoroughly, will effect the object desired, and boiling by live steam is far too costly. Exhaust steam is usually employed, and not only is this only partially efficient, but the grease from the steam adds to the subsequent difficulty of treatment.

Confining my attention, therefore, to the lime and soda treatment as the now generally recognised best method of softening, I observe that the problem of constructing a softener divides itself broadly into three stages: (1) a method of introducing the reagents (lime and soda) in proper quantity, and with regularity and certainty; (2) a reaction chamber in which the chemical reactions may take place; and (3) some efficient method of clarifying the treated water.

(1) *The supply of reagents.*—Obviously a safe and sure method is to introduce the chemicals in bulk into a measured quantity of the water to be treated, and mix the whole up by some means. This was the method adopted by the late Dr. Clark in his early investigations into this subject, and for which he took out a patent in 1841, and which has come to be universally known as the Porter-Clark process. This is also the method adopted in the "Archbutt-Deeley" process and is thoroughly effective so far as it goes, but the size of the tanks and space required to do this properly and without requiring the process to be repeated too frequently is a serious drawback, hence the resort to mechanical means for introducing the chemicals continuously into a regulated flow of the water to be softened, thus making the apparatus continuous instead of intermittent. A considerable saving of space is to be effected by a reliable device of this kind, as also in the first cost, and the cost for attention. Indeed, this matter of first cost so persistently confronts the engineer that recourse is had by some makers to what are, undoubtedly, only partially effective methods of treatment. Prominent amongst these must be mentioned the use of milk of lime instead of lime water. Not only is there a difficulty in mixing and keeping mixed the lime and the water to ensure a uniform mixture being passed over, but there is always a quantity of earthy matter with the lime which is constantly altering the mixture, and makes it impossible to be sure of its strength. Still, as before mentioned, this is a method in favour with some engineers because it keeps the apparatus compact and low in first cost, but it certainly is not reliable, nor should I think, from the standpoint of the chemist, can it for a moment compare with the method of using a saturated solution of lime water. It is also interesting to note here that the idea of using saturated lime water—not milk of lime—originated with Dr. Clark; at least it is mentioned in the patent before referred to. The well-known property of water to dissolve and hold in solution lime to a fixed amount, is a most valuable one when dealing with this problem. It is only necessary to ensure a steady flow of water through a mass of lime thoroughly stirred up and to dissolve out the maximum amount of lime with certainty, when, after allowing the water time to settle out any particles of lime in mechanical suspension, the object is accomplished.

The Reisert patent lime saturator consists of a conical vessel standing with the point downwards (see Fig. 1). Slaked lime is introduced into the bottom or pointed end of the cone through the pipe, A, and a regulated stream of the water to be softened is caused to flow through the mass by carrying a pipe, B, to the bottom of the cone. The flowing water will effectually stir up the lime, dissolving as it goes, and rising through the cone with continually reducing velocity, finally flowing over through pipe, C, as a clear stream of saturated lime water. The bottom or

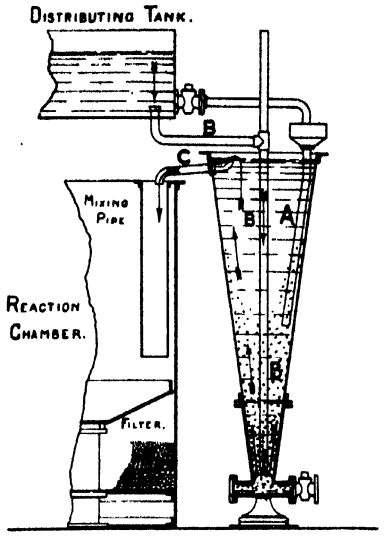

Fig. 1.

pointed end of the cone acts as a perfect mixer, whilst the ever widening upper parts acts as an efficient decanter.

With regard to the soda, the required quantity is dissolved in water and introduced by some mechanical device, such as tipping buckets of various kinds, syphons, water wheels, driven by the incoming water operating scoops or buckets, or in some cases by compound pumps with rams of different sizes which deliver the exact proportional quantities of both lime and soda. Ingenious as some of these devices are, they are liable to derangement and require constant attention to secure their good working, with the result of frequent failure, or only qualified success.

In the Reisert Softener—presently to be more particularly described—the supply of the soda solution is effected

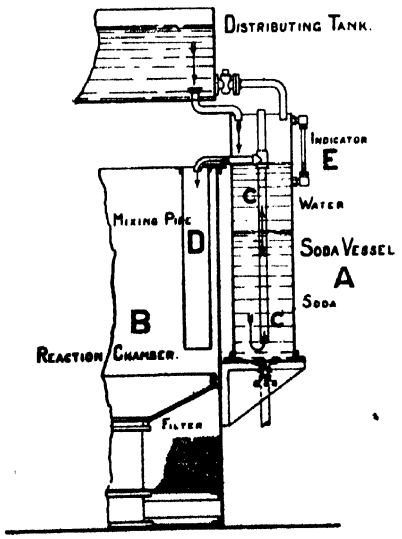

Fig. 2.

in a most simple manner without any moving mechanism at all, by taking advantage of the difference in specific gravity between a solution of soda and water. The soda solution is run into a cylindrical vessel, A (see Fig. 2), standing alongside the reaction chamber, B, and from the bottom of the vessel a pipe, C, rises to within, say, a few inches of the top, where it turns through the side of the vessel and discharges into the mixing pipe, D. It is found, that if a stream of water is allowed to flow gently on to the top of the soda solution, it will, without mixing with it, displace the soda solution—piston fashion—through the pipe, C, before mentioned, until the last drop is passed over. In so doing, the "head" of water above the pipe will be a constantly increasing one, rising more and more as the solution goes over, and by putting a gauge glass, E, or float to the upper part, one can see at once when all the solution has gone over by the water line suddenly falling. Advantage is taken of this property as a means of indicating to the attendant when the apparatus requires recharging.

Having thus briefly touched upon the mechanical supply of the chemicals, I now pass on to notice—

(2) *The reaction chamber* where the chemical reactions take place due to the mixing of the lime and soda, and the chief thing to be said about this, is that it should be of such ample dimensions as to allow the chemicals time to perform their functions. A rough but safe rule is to make it equal to the hourly duty of the plant; it cannot with safety be made less, and in some cases I have known it might, with advantage, be made much larger. Another reason for this, is that the reaction chamber is also a precipitating vessel for the carbonate of lime thrown down, a starchy looking liquid which is slow in settling, but which must be separated by some means from the water before it can be used and which brings me to stage 3, *viz.*:—

(3) *Efficient means of clarifying the treated water.*—It is found in practice, that there is a great variation in the velocity with which these precipitates fall. They are all slow and greatly hamper the engineer at this stage. In the Archbutt-Deeley process first mentioned, in which the reaction takes place in large tanks, recourse is had to mixing the newly treated water with the mud of the previous charge, and it is found that the resettling of the mud helps to carry down the finer particles from the new reaction, and so hastens the settlement of the treated water. In other cases, shelves or partitions are arranged upon which the precipitates can rest as in the Dosrumaux apparatus, so shortening the time as much as possible, but whatever device may be adopted to settle the precipitate, it is found that there is still a need for further treatment before the water can be said to be in a condition fit to use, and it is safe to say that no water softener is complete without some kind of filter. A common method is a filter of wood wool, acting upwards. This speedily gets foul, and as there is no way of cleaning it, short of taking it to pieces and washing it, it is a device peculiarly adapted to bring a softener into disfavour with the attendants. Gravel and sand filters with some device for cleansing them are the only kind that have given good results, and it is here that the excellence of the Reisert Automatic Filter appears, as it possesses the property of attending automatically to its own cleansing, and entirely removes all care and anxiety from the attendants on that score—no small relief, as those who have had practical acquaintance with water softeners can testify.

Having thus reviewed the three essential stages of water softening, I will now describe the Reisert Softener, in which these essentials are carried out in a more perfect manner than heretofore, some of the points of which have been already touched upon.

The annexed illustration, Fig. 3, is a diagramatic view, all details of staging, &c., being omitted for purposes of clearness.

It consists of a crude water distributing tank, C, E, A; a lime saturator and decanter, B; a soda vessel, D; a reaction chamber, F; and an automatic self-cleansing filter, K.

The distributing tank, C, E, A, is divided into three compartments. A is a lime slaking compartment in which the lime is slaked and run in proper quantity to

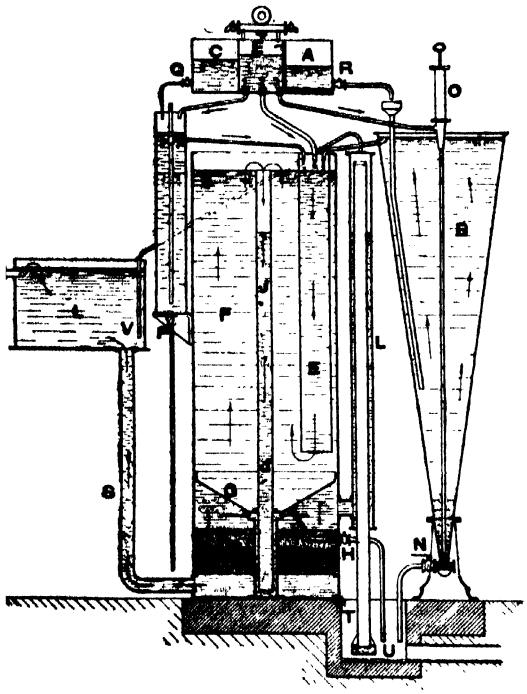

FIG. 3.

the bottom of the conical vessel, B, through the cock, R, and down pipe with funnel. C is a soda dissolving chamber in which the required quantity of soda is dissolved and run into the soda vessel, D, through cock, Q. The centre chamber, E, receives the crude water at a rate corresponding to the hourly capacity of the plant. At the bottom of this chamber are three gauged openings, 1, 2, 3, of which the centre one (2), is by far the largest, and discharges a regular quantity of crude water into the mixing pipe, E. The next in size, (3), discharges a lesser quantity of water to the bottom of the conical vessel, B, through the pipe, O. This water, in flowing through the lime, keeps it continually stirred up, and rising through the cone at a decreasing velocity drops the particles of lime in mechanical suspension, and finally runs over from the top of the cone into the mixing pipe, E, as a stream of clear saturated lime water. The size of the gauged opening (No. 3) is regulated to pass such an amount of water as will dissolve the necessary quantity of lime and keep the solution up to saturation point for a run of 12 hours (the usual limit of time). The gauged opening, (1), the smallest of these, discharges such a quantity of water into the top part of the soda vessel, D, as would fill the vessel, D, in 12 hours, but as this vessel (we assume) is already filled with a solution of soda, of the proper strength, the crude water lies on the top of the heavier solution and displaces it over by the central pipe into the mixing pipe, E. Thus we have three streams entering, E—a crude water stream, a lime water stream, and a soda stream—the three combined representing a flow equal to the hourly duty of the plant. It will be admitted, I think, that nothing could be simpler or more certain of action than three streams derived from a common head of water, and which will vary, if they vary at all, in an equal ratio if the "head" varies, and stop altogether when the supply of water stops. The size of these gauged openings is settled by trial runs in erecting the plant, and once ascertained, no further attention is needed unless the character of the crude water changes.

Following the course of the arrows, the mixed water rises through the reaction chamber, F, when the chemical reactions are completed, the resulting precipitate falling on to the conical bottom, G, whence it is periodically flushed off through the cock, H. Although a considerable quantity of the precipitate is disposed of in this manner, the finer particles—varying with the nature of the water—refuse to settle, and flow over with the water into the pipe, J, and are separated by the sand and gravel filter, K.

The water descends through the filter and issues by pipe, S, through storage tank, L, by the pipe, M, ready for use. Attention is specially directed to the perfect action of this filter. It will be obvious that the head of water available for forcing the water through the filter will be the difference between the water level in the pipe, J, and the level in the tank, L, and that as the resistance of the filter increases, owing to the deposit of carbonate of lime upon it, the height of the water in J, will increase until finally, the pipe would become full, and the reaction chamber itself would overflow were it not that, during this time, a corresponding pipe, L, in communication with the space above the filter bed has been rising in sympathy with it. It will be seen that the pipe, L, contains an inner pipe, and with a water lute, T, forms a syphon, so that as soon as the filter bed becomes so choked as to require a head of water which will bring the water well above the top of J, the inner pipe in L, overflows, and acting as a powerful syphon, reverses the current through the filter bed, drawing back the filtered water stored in, L, and so thoroughly cleanses the filter. An air pipe, U, breaks the syphon at the proper time, and the filtering action re-commences. Exactly how often this cleansing takes place depends upon the water being treated. Obviously, in the case of a water in which the precipitate settles slowly, a larger quantity will come upon the filter and the re-flush will be more frequent, but whatever the period may be, it is important to note that it can only occur as often as necessary, and is entirely automatic in action—a great advantage and an indispensable one when plants work through the night, and when the attention given is of a very ordinary kind. The daily manipulation of the plant is quite simple. The proper quantity of lime (approximately settled from the analysis), and finally decided by test, is run into, B, every 12 hours, and the spent lime is flushed off at, N. Similarly, the proper quantity and strength of soda is run into, D, the displacing water having previously been run off by tap, P. This, and the occasional opening of the mud outlet, H, is all the attention requisite, and it is quite within the compass of an ordinary labourer. The time taken should not be more than one hour per day of 12 hours, so that the cost of attention is very low. The plant works well, and the water can be softened down to a determined point with regularity and certainty.

On the subject of the cost of softening by the system, the table on next page is compiled from the results of plants recently erected.

Water softening by lime and soda, whilst satisfactory for many dyeing and manufacturing purposes, brings with it certain disadvantages when the softened water is used for boiler feeding, *viz.*, the accumulation of sodium sulphate in the boiler, causing the latter to foam or "prime" badly, unless frequently blown off, and which also attacks the gunmetal fittings, eating away gauge cocks and valves in a serious manner. The first-named drawback is most seriously felt in boilers of the locomotive or tubular type, and many attempts have been made to use some other substance than soda in its various compounds, notably barium carbonate. It will be seen at once that if this substance could be used instead of soda, the result would be the formation of barium sulphate instead of sodium sulphate, which would be separated in the filtration, and thus an end would be made of the troubles of foaming, and the waste of the fittings. Such an apparatus has been successfully designed, of which the following is a description. The annexed illustration, Fig. 4, is a diagrammatic view designed rather to show the principle upon which Messrs. Reisert have proceeded than to burden this paper with unnecessary details.

Following the lines of their lime and soda plant, they use the same system of lime supply, but instead of soda they use a suitably prepared barium carbonate introduced in bulk into the reaction chamber, D, where it lies in the

conical bottom, D′. The crude water is caused to stream through this powder by the pipe, C, so keeping it constantly stirred up, and floating about in the reaction chamber, D, the lime water meantime entering in a manner similar to the previously described plant. It is found that the barium carbonate effectually attacks the calcium and other sulphates, decomposing them and forming barium sulphate and calcium carbonate, and that it is more active when used along with the lime. The precipitate so formed settles down in the reaction chamber, D, and mixes with the barium carbonate, and goes on accumulating, the water finally passing off through a sand filter, H.

How long this accumulation of precipitate or mud will go on depends on the nature of the water being treated, but, obviously, the reaction chamber, D, would get full in time, and cocks are placed on the shell of the chamber, so that the attendant can ascertain occasionally how the accumulation is going on. The mixture of the mud with the barium carbonate is not found to interfere in any way with its action, and the quantity added is regulated by the time that the plant will run before the mud must be flushed off. This may be several days, or even weeks, but the essential point is to so gauge the quantity of barium carbonate introduced (in bulk) that it becomes spent about the time that the plant becomes "gorged," so to speak, with the mud, when the whole is flushed off, and the plant is re-charged. The barium carbonate being expensive, it is important that none of it be lost by flushing off too early or too frequently, and for a like reason the filter, H, is cleansed by allowing a quantity of impounded clear water to stream backwards through it into the reaction vessel, so that any barium carbonate which may have got lodged in the filter may find its way back into the reaction chamber. Using the barium carbonate carefully in this way, the process compares favourably with the lime and soda treatment in cost of running.

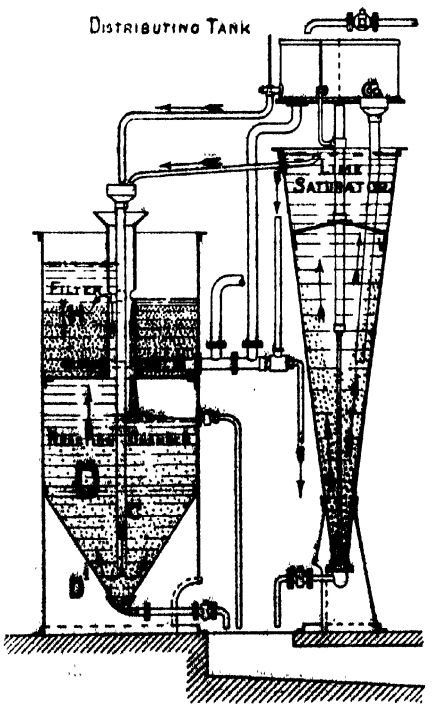

Fig. 4.

The first cost of the plant is about the same as for lime and soda, whilst the advantage of the absence of soda salts in the boilers renders the system incomparably superior for locomotives and boilers of a tubular type.

Discussion.

The Chairman said there was no doubt that in the subject of water softening we were very much behind. He was struck by the number of plants under the Reisert system said to be fixed abroad, and he doubted whether the whole number of plants of all types erected in England would equal that number. With regard to the barium carbonate system, he thought if it could be run as economically as the soda process, there would be the additional advantage that this re-agent is most efficient for removing iron from water. He understood Mr. Royle to say that the sulphate of soda in feed water was responsible for the destruction of gun metal fittings, whereas he (the Chairman) thought it was due to the alkalinity of the water itself. He thought, however, that the influence of even minute amounts of nitrogenous matters had been too much overlooked. He had experienced cases of rapid corrosion of gun-metal fittings traceable to slight sewage contamination of the water. Even with the minute amounts present in normal river waters, the ammonia carried over by the steam had a corrosive action, but where serious contamination of the water existed, the action was very pronounced. It was especially with alkaline water and during priming that the mischief was done.

Dr. W. R. Ormandy was somewhat astonished that the lecturer had dismissed with such scant attention the possibilities of the use of any chemicals, other than lime and

soda ash, for the purpose of water softening. Where the water was required for boiler feed purposes and where the bulk to be treated was not very great, there were very many arguments in favour of the use of a mixture of caustic soda and carbonate of soda in proportions suitable for the water under treatment, where the use of such a mixture was from the chemical nature of the water, possible. The great simplicity introduced by the use of a single solution was more than enough to counterbalance the slightly increased cost. Where the feed water could be warmed by means of exhaust steam, it frequently happened that the cost under these circumstances was actually not greater than where the lime-soda process was used. Although the apparatus described was very ingenious, it did not overcome many of the difficulties inherent in the use of lime-soda mixtures. The solubility of lime varied tremendously with the temperature, and it was not by any means easy to rely upon getting a saturated solution. It was stated that the presence of alkaline salts in the boiler had caused trouble with the gauge taps, gauge-glass fittings, and the blow-off cocks. This was certainly true where the process was not properly carried out, and where the amount of alkali used was excessive and allowed to accumulate and concentrate in the boiler. The use of iron fittings practically overcame this. Sand-filters were not an unmixed blessing. The fact that the majority of the makers of water-softening machines in the past had worked on unscientific lines, had enabled the sand-filter makers to obtain a strong footing. The majority of the old type of water softening plants made use of an ascending current of water through which the sediment settled. This was obviously wrong in principle, and after a considerable amount of work, his firm had succeeded in making a separator in which the path of the liquid was practically horizontal, and which resulted in an efficiency far exceeding that of the vertical type. With reference to the case at Leicester, the speaker thought that it would be interesting to have complete analyses of the water; the case was so extraordinary that further details were required to substantiate it. There were, undoubtedly, many very interesting points in the apparatus brought before their notice that evening, and apart from the inherent defects to which the process and the methods were liable, it would probably give very fair results.

Mr. FRANK SCUDDER said that many of the filters in connection with these plants were a source of trouble. In the filter shown upon the screen, the filtering material was graded, and he should like to know whether, after the self-cleansing of the filter took place, the material became mixed or settled down in layers. Water alone was not sufficient to efficiently cleanse the filtering bed. Air was used to disturb the material and loose the deposit—the water then washing away the deposit. A good sand filter with such an arrangement used only about 7 per cent. of the water filtered for washing purposes, and he wished to know what quantity was required for the filter under discussion.

Mr. ROYLE, in reply, said that it was impossible, in the brief space of time allotted for a paper of this kind, to touch upon many points of great importance in connection with water softening, some of which had been opened up in the discussion. In reply to Dr. Bailey, as to the cause of the wastage of the boiler fittings, this was a matter for the chemist, and he was much interested in Dr. Bailey's suggestion as to the cause of this waste. Replying to Dr. Ormandy, he said it was undoubtedly economical to feed boilers with hot water, but the difficulty was to so arrange the demand of the boilers that it kept pace so to speak with the softener. Boilers were intermittent in their demand, whilst a softener is best when working at a uniform speed. Storage of the treated water was, in most cases, absolutely necessary, and this defeated the idea of economy, as if the water was stored it necessarily cooled down. He failed to see how iron cocks were going to be satisfactory on high-pressure boilers. He would also say that the amount of flush water used in the Reisert plant was about 25 per cent. of the hourly duty. How often the filter flushed, varied with the nature of the precipitant, but it was a bad case if the flush water reached 5 per cent. of the duty of the plant—more often it was nearer 2 per cent.

Meeting held at Manchester on Friday, May 4th, 1906.

DR. G. H. BAILEY IN THE CHAIR.

THE BORING CAPABILITIES OF A WOOD-INSECT, WITH PARTICULAR REFERENCE TO ITS PENETRATION OF SHEET LEAD.

BY WM. BEAMONT HART, F.I.C., F.C.S.

In the year 1895 I was engaged by the Ottoman Government in the erection of plant for smokeless-powder production, at Baruthane, nine miles from Constantinople, on the Sea of Marmora. Timber was required early in the building operations, and it was necessary to contract for it at once. The supply of timber, either native or imported from the adjacent countries, is fairly plentiful, the chief varieties being: *Fil-yi-ass*, or white deal; *Tchee-de-ne*, or red deal; *Num-se-cal-agatch*, or Austrian deal; *Tchamm*, or pine; *Mey-shey*, or oak; *Gul-gen*, or beech, &c. *Tchamm* and *Num-se-cal-agatch* were chosen, chiefly on account of their resinous nature and their greater length. At this time I had no knowledge of the boring power of insects, the timber being selected from considerations of strength, dimension and quality only.

When the plumbers arrived from England, and the lead work was in fair progress, one of these men, who had been out in South Africa on similar work, mentioned the trouble they had experienced there by leakage due to holes in the lead, caused by the insect usually termed the wood-worm, though they had never been able to obtain a specimen.

About a week after this conversation, one Monday morning about 11 a.m., my attention was called to the wooden floor of one of the sulphuric acid chambers, where the sheet-lead had been laid down temporarily for strap-cutting. I saw a small hole in the upper surface of the lead, and, by the aid of a pocket glass, noticed a distinct boring movement in and below the hole. On lifting up the lead I found an insect in the timber with its head just above the wood-flooring, its augers still moving and some slight quantity of fine dust on the floor. With a piece of wire I dislodged and secured the insect, and found the hole in the wood to be about 2½ ins. deep, passing, somewhat obliquely, through the flooring board into one of the joists below—from which some wood borings were obtained—and there it ended. No trace of any other outlet could be seen, so that it seemed reasonable to conclude that the insect, as found, could not have entered into the wood from outside while the joist was in position, but had either been deposited as an egg in, or entered, in the larval stage, into the wood, and, after reaching maturity as a full-grown fly, had attempted to gain its freedom by boring through the timber and started operations on the lead.

FIG. 1.

The lead sheet was one-eighth of an inch in thickness, and the hole, as can be seen, in Fig. 1, is countersunk, the lower opening being 6·4 mm. diameter at its widest part and 5·2 mm. diameter at its narrowest part, whilst the upper opening is about 3·2 mm. diameter all round, though the openings are not concentric. The sides of the hole are scored more or less deeply by indentations, in such a manner that the action and direction of the boring organ can easily be traced, being generally in the opposite direction to that of the hands of a watch as the insect worked from the lower to the upper surface of the lead—though some boring marks are in the contrary direction—and are for the most part continuous; the whole result, when looked through from the lower to the upper surface, resembling the rifling of a gun-barrel.

From near the mouth of the insect a pair of mandibles extends, as shown in Fig. 2, each consisting of three cutters

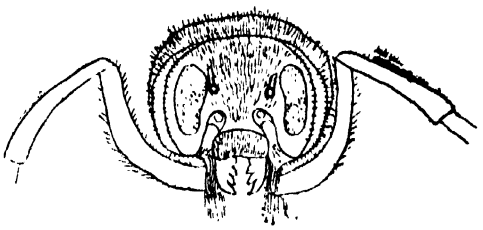

FIG. 2.
Front view of head showing mandibles.

of varying size, increasing in length but decreasing in width from the mouth outwards, each complete mandible being about 0·7 mm. in length, 0·55 mm. diameter at its widest part nearest to the head and ending in the first or largest cutter. From this examination of the mandibles, the countersunk shape of the hole in the lead can readily be understood, the attack being made initially at a point, and as the width of each mandible increases from its largest cutter, furthest from the head to the smallest cutter nearest to the head, so the diameter of the hole increased as the boring operation proceeded from the lower to the upper surface of the lead sheet. It will also be comprehended that had the insect completed its work of escape unobserved, the hole would have been cylindrical instead of countersunk.

The length of time the insect had been actually occupied in boring the hole through the lead is not known, but the maximum time can be definitely stated. The lead sheet had been laid down on the previous Saturday, so that 48 hours was the outside limit, and, judging from the hole formed, probably in a further 12 or 16 hours' time, the prisoner would have escaped.

On investigating the entomology of the subject, as regards the penetration and boring of timber by injurious insects, I find the following have the power and habit of damaging pine and fir:—

Sirex gigas, or Giant Wood-wasp—the timber wasp of Germany; *Sirex juvencus*, or Steel-blue Wasp; *Lophyrus pini*, or Pine Sawfly; *Hylobus abietis*, or Pine Weevil; *Hylurgus pineperda*, or Pine Beetle; *Tomicus typographus*, or Bark-beetle of Germany; *Pissodus notatus*.

The last mentioned has been found ravaging the Austrian pine, but, as far as I am aware, has not been seen in the British Isles. *Tomicus typographus* has repeatedly attacked the German pine forests, its ravages occurring to such an extent that its old popular name of "the Turk" was revived, a name referred to in old German liturgies. The bark-beetle calamity of Bohemia lasted from 1871 to 1875. All the others have been found in our islands infesting pine and fir trees, to a greater or less degree, according to seasons.

The insect found is undoubtedly the male *Sirex gigas* fly of the sub-group of *Sessiliventri* of the *Hymenoptera* or membranous-winged family of Mandibulata. The female bores, by its ovipositor, into the bark of the healthy tree after felling, or of the fallen tree lying in the wood—but not generally that of the growing timber, and here deposits its eggs, the larvæ from which then burrow into and feed on the solid trunk. Normally in about seven weeks, these then merge into the chrysalid stage, and finally, in about another month, transform into the complete fly. If the larva has not changed into the chrysalid before the autumn, the fly will not appear before the following summer or even until a much later period. They usually exhibit themselves singly or a few at a time, and sometimes over a period of several years from one trunk.

One curative device proposed was to strip off the outer bark, and so cause a vigorous flow of sap, which kills the larvæ. Theobald, in his "Reports on Economic Zoology to the Natural History Section of the British Museum (1903—4)," points out the fact that many larvæ of the *Sirex gigas* and *Sirex juvencus* hatch out even after the wood has been well creosoted, and states that there are no remedies against the *Sirex* flies.

With regard to the perforation of lead by insects, Hartmann, in the "Gesundsheit-Ingenieur," for 1891 (this J., 1891, 683), drew attention to the damage done to leadwork, caused by the larvæ of the wood-worm. Examining the leaks from a lead pipe, he traced the cause to a live wood-worm which was found with its head protruding through the wall of the pipe; the outer opening of the hole was 7 mm. by 4 mm., the surface of which was scratched with fine indentures.

In Kerl and Stohman's "Handbook of Technical Chemistry" mention is made of the fact that certain wood-worms (*Sirex gigas*) perforate sheet lead, the holes made showing rough surfaces with fine indentures. At the Muldener Hütte, holes up to 6·5 mm. diameter were found in sheet lead which was fastened to wood-work. In this particular case, the insect is stated to belong to the *Coleoptera* family.

Scheurer-Kestner (Comptes rend., 58, page 518) mentions a case where cylindrical holes were found in the lead lining of a beam of a new sulphuric acid chamber, and this in a few days after covering. In one hole the semi-developed body of an insect was found, partly in the lead and head first, the diameter of the hole corresponding exactly to that of the body of the insect, so that the latter could not turn round in order to escape.

From my observation, it is quite evident that the penetration of the lead was effected by the fully-developed fly and not, as stated by other observers, by the insect in its earlier or worm stage. Though the worm can penetrate into and through the wood, the capability of boring through lead is probably, therefore, only within the power of its final stage

The insect in its last stage works its way from the sap of the timber towards the bark, and it has been suggested, in order to avoid such results above related, to place the bark side of the timber furthest away from the lead. This might be done when the presence of the insect is suspected, and may be effectual, but I am afraid it would entail too much supervision and never be carried out systematically. Since the cause of the perforation was only observed and captured after the timber-work had been erected, and before any published information on the subject had been seen, this was entirely out of the question.

The main consideration, from an engineering point of view, now was, how to prevent damage to the lead plant, for it was very improbable that the insect found would be the only one present. Taking it for granted at the time that the insect worked from inside outwards in order to effect its escape, and not from outside inwards, the usual tar-coating generally adopted for the preservation of the timber would be no protection to the lead against the insect already in the timber. The lead floors and upstands of the chambers and also the lead cisterns were the chief anxiety. Practically in all other parts of the chambers the lead is never in direct contact with the timber, except at the straps, so that the insect could fairly easily escape, and even if perforation did happen, it would only be in the gaseous part of the chambers where repairs would be comparatively simple. I suggested the coating of the timber, wherever it would be covered by the lead—and before laying down the lead—with a thick

mixture of gas-tar and creosote oil, so as to form a thick viscid layer—a "tangle foot fly-paper" on a large scale—between the timber and the lead, which, being out of contact with the outer air, would remain elastic or only harden slowly. When the insect had bored through the wood, and before it could attack the lead, its mandibles would be so entangled, tired and eventually rendered so useless by this composition, that, in my opinion, perforation would be prevented.

Others suggested that a sheet of zinc might be placed between the wood and the lead, but anything thinner, though harder than lead, I deemed untrustworthy for two reasons, *viz.*:—(1) If such an insect could perforate sheet lead of one-eighth of an inch (3·2 mm.) in thickness, it might also pierce zinc, and (2) injury might be done to the lead itself, when laying it down, by the sharp corners and edges of the zinc; this was a far more practical objection.

An insect, known as *Zopherus melicanus*, has recently been found that is stated to be able to cut sheet zinc with its mandibles. A pair of these remarkable little creatures actually succeeded in biting their way out through the zinc cover of a glass jar in less than 48 hours.

My proposal of a tar layer between the wood and the lead was negatived, and reliance was placed solely on the usual tar-coating on the outside of the timber, an untrustworthy procedure as later events proved, though every care was taken by repeated coating, thinner at first so as to soak well into the wood, and ending with thicker finishing coats, crude creosote oil and gas-tar from the gas works being used for the purpose.

When the plant was completed, the chamber floors and the cisterns were flooded with water and some perforation was discovered in the first chamber floor, the same floor where the insect had first been found, and though these later holes were near one end of the chamber, they were not restricted to the region of any particular joist. After running off the water, the positions of the holes were found, repairs effected, and the chambers sealed up, except, of course, for the entrance from the burners.

Some interval of time elapsed between the completion of the plant and the commencement of work with it, but when the chamber process had been in operation for some time, further slight leakage was observed, and, as even by the most careless working of chambers—and normal working of chambers is difficult to obtain by native workmen—the lead floor is the last to be affected, it seemed that insect life was not yet exhausted in the timber of this same chamber. No other chamber was so affected, but, as far as I remember, one lead cistern had one leakage. The chamber was emptied, cleaned, examined, the perforations marked out, soldered up, and work again commenced. However, after some time, no further leakage was observed and the trouble ceased.

In all probability the insect life was confined to a few of the logs, though all the timber was examined for soundness before arrival on the works, and the repeated trouble experienced confirms the entomological statements of their irregular habits of exhibition.

My conclusions are (1) that the insect works its way from the inside of the timber outwards, and not, at least in its final stage of life, from outside inwards, though this may happen in earlier stages or later generations; (2), that though outside tarring may prevent the deposition of the egg in or the entrance of the larva into the wood, it is of no value in preventing the exit of the full-grown boring fly from the wood, and possible damage to the lead by perforation, wherever the exit hole in the timber is covered by lead; and (3), that even a thinner yet harder metal, such as sheet zinc, may be unreliable as a preventive against penetration.

Mr. J. R. Hardy, of the Manchester Museum, has been kind enough to give me some information as to the injury done to many varieties of timber by insect life in general, both in England and abroad; and in his opinion resinous woods are preferred, though harder woods such as hickory and mahogany are also affected. The thin sheet lead of tea boxes has repeatedly been found to be perforated, but the fact that sheet lead of one-eighth of an inch in thickness can be pierced through was unknown to him.

Considering the general use of timber, of all classes and from various countries, in conjunction with lead for chemical and other works purposes, it seems remarkable that such perforation as I have described has rarely been observed at home. In "Ormerod's Annual Entomological Reports" there is but one record of the perforation of lead pipe in this country, and that by the *Sirex juvencus*. This was noted in 1889 at the Manor House, Newbury, Berkshire, the lead pipe being attached to wood-framing. Perhaps our cold climate has much to do with it, but in view of the enormous amount of timber imported into this country, the possibility of damage from insect life should be realised and precautions taken by a strict examination of all timber used, in important work at least

It may be added that the *Sirex gigas* has an attacking parasite, the *Thallasa lunator*, of the Ichneumon class, not a rare insect in Norway.

Scottish Section.

Meeting held at Glasgow on Tuesday, March 27th, 1906.

MR. DAVID PERRY IN THE CHAIR.

THE DETECTION OF BEEF FAT IN LARD.

BY H. DUNLOP.

The detection of beef fat in lard has been held to be an easy matter by some analysts, whereas recent investigators have clearly shown that it is really a matter of considerable difficulty, and have thus been unable to confirm the statements made by older authorities as to the distinctive forms of crystals yielded by pure and adulterated lards respectively. The more one examines this question practically, the more one is convinced of the uncertainty of the ordinary methods of determining whether a sample of lard is genuine or not, and it is, therefore, of importance that an analyst should have substantial grounds on which to base the conclusions he has come to. With this object in view, I have carried out an investigation on pure and genuine fats rendered by myself, the observations including the determination of the constants employed generally in their analysis, as well as an examination of the structure of the crystals obtained from solutions of the fats; and in the present paper I propose to give a description of the results obtained.

The various fats were cut from the specified parts of the animal, and rendered at 90° C., the residual tissue being in all cases well pressed, in order to remove any of the harder portion of the fat which it might retain.

The results of the examination of these lards, as well as beef, mutton and cotton-seed "stearines," including the iodine value, ether washed deposit (Keating Stock's method), &c., are given in Tables A to E.

The solidifying points were determined by first liquefying the fats at about 50° C. before pouring them into the tube in which the determination was made. The melting points were in all cases determined by capillary-tube method, the tubes being allowed to stand for 24 hours after filling. The Zeiss butyro-refractometer reading was taken at 40° C. for lard, and at 45° C. in the case of beef and mutton fats.

On comparing the iodine values and refractive powers given in Tables A and B, it will be observed that the latter rises and falls with the iodine value; in fact, it would seem possible to tell within a few units what the iodine value of a sample of lard would be, from the determination of its refractive power. This relationship is also shown in the case of beef and mutton fats.

Although, generally speaking, the amount of ether washed deposit increases with the melting point, as shown by Keating Stock (Analyst, 19, 2), this is not always

Beef fat (from kidney suet)	35·9	42·3	—	35·2—39·0	48	16

the case, as an examination of the figures in Table A. will show. Taking the solidifying points in preference to the melting points (the determination of which, especially in the case of soft lard, leaves much to be desired) and comparing these with the amounts of ether washed deposit, it will be observed that the latter does not always vary proportionately to the former. It is hardly necessary to point out that this fact, as also the great variation in the amount of ether washed deposit, has an important bearing on Keating Stock's method of estimating beef fat in lard.

When dealing with commercial lards, as shown by various observers, the iodine value alone generally fails to give any indication of the presence of beef fat, as vegetable oils, such as cotton-seed, are added in sufficient quantity to give a normal iodine value. Unfortunately, the detection of cotton-seed oil in lard by means of colour tests, is rendered uncertain by the well-known fact that lard from hogs fed on cotton cake gives the characteristic reaction with Halphen's test. While several writers on the subject have pointed out the danger of basing conclusions on a positive Halphen test, until quite recently no figures had been published, showing whether the iodine value of such lard is in any way abnormal. I have recently had the opportunity of testing this for Messrs. Tatlock and Thomson, who, in a recent paper read before this Society, showed the effect of cotton cake feeding on the milk of a cow.

The pig selected for experiment received daily, for six weeks previous to killing, from 1 to 1½ lb. decorticated cotton-seed meal with its other food. Portions of the fat were taken from the indicated parts of the animal, and, after rendering, the iodine value and refractive power were determined and the Halphen test applied. The results are given in Table B:—

It is somewhat interesting to note that the fat taken from the external parts gave a stronger colour than that from the internal parts. The iodine values and refractive powers are, however, quite normal, and give no indication of cotton-seed oil as such having passed into the fat.

Of the many modifications of Relfield's test, that due to Keating Stock is, perhaps, the best known, as by this method, it is claimed that a quantitative determination of beef fat in lard can be made, and also that smaller quantities of the former can be detected than by other methods. In the above method the standard mixtures of lard and beef fat employed should, according to Keating Stock, give a series of ether washed deposits, the amount increasing with the percentage of beef fat. While this is certainly the case with standards containing from 15 per cent. and upwards of beef fat, I have found that, in some cases, the addition of smaller quantities of beef fat fails to influence the amount of ether washed deposit, as the following example will show: Lard No. 4, Table A, of solidifying point 24·3°, was chosen as representing a soft lard, and mutton fat No. 15, of solidifying point 40° C. added in quantities of 10 and 20 per cent. The solidifying points and other washed deposits were then determined in the mixtures thus prepared, with the following results as shown in Table C:—

TABLE C.

	Ether washed deposit.	Solidifying point.
		°C.
Pure lard No. 4	7	24·3—25·5
With 10 per cent. of No. 15	6	25·0—26·5
With 20 per cent. of No. 15	20	26·3—no rise.

TABLE B.

Lard from Pig fed on Cotton-seed Meal.

Part of animal.	Iodine value (Wijs).	Zeiss butyro-refractometer at 40° C.	Cotton-seed oil, per cent. by Halphen's colour test.
Shoulder	67·8	50·7	10
Leg	65·1	50·3	8
Back	64·8	50·0	10
Leaf	58·3	49·0	2
Kidney bed	58·3	49·0	6

The result of the Halphen test is expressed in percentage of cotton-seed oil, an edible oil being selected as a standard. It will be, of course, understood that these figures only give an indication of the relative intensity of the colours, which, with one exception, were very distinct.

These results, as also many attempts to obtain beef crystals from mixtures containing smaller quantities of beef fat, suggested an examination of the "stearine" obtained from lard and beef fat respectively, and especially that from hard lard. Quantities of "stearine" from

fats (12, 13 and 15, Table A.) were, therefore, prepared in the following manner:—

An ethereal solution of the fat was allowed to crystallise, and after decanting off the mother liquor, the crystalline deposit was thoroughly washed by repeated agitation with ether, and collected on a filter, where it received a final washing with ether. After drying at 40° C. the iodine value and melting point of the superfused crystals was determined. To find the relative solubility in ether, the following tests were made:—

0·5 grm. of each of the "stearines" was treated in small stoppered bottles with 50 c.c. of ether of 0·7175 sp. gr., previously cooled to 12° C., and after agitating the mixtures, the bottles, contained in an insulated box, were kept for three hours at a temperature of from 12°—13° C. The amount of dissolved "stearine" was then determined by evaporation of the filtered liquid. Repeated crystallisation from ether proved that the solubilities obtained by this method were relatively correct.

A further test was also made, using petroleum ether, sp. gr. 0·648. The results are stated in Table D, which also includes cotton-seed "stearine" prepared from the commercial article and recrystallised several times from ether.

As previously stated, the melting points in above Table refer to the crystals in the superfused state, the so-called double melting point being observed in several cases and more especially in the case of the superfused crystals from lard.

It will be observed that the melting point of the crystals obtained finally by this method of crystallisation, is several degrees below that of pure tristearin which is given by Lewkowitsch at 71·6° C., and slightly above that of pure tripalmitin.

The crystals obtained finally from lard in the fifth crystallisation were considered free from unsaturated glycerides, as shown by the iodine value. I do not attempt to draw any conclusions from the melting points of these substances, as further investigation would be required to enable one to say whether certain glycerides are common to the three fats.

Coming now to the microscopical examination of the "stearine," which is certainly the most important part in the testing of lard for genuineness, it will be observed in the first place that, although the form of the crystals from normal lard and beef fat respectively are quite distinct, the "stearine" from a mixture of these fats, in place of showing well-defined "beef forms" side by side with lard crystals, generally gives a form which is a modification of the lard form.

"Stearine" from such a mixture, when examined at a magnification of, say, 30 diameters, often shows a number of "plumose groups," which at this low power may be easily mistaken for typical beef crystals. If, however, a higher power be employed, say, 300 to 400 diameters, these groups are seen to be composed of narrow plates with oblique terminals, and quite distinct from the fine rods or needles given by a first crystallisation of beef fat. The subject is further complicated by the fact that some genuine lards give, on crystallisation, abnormal forms, which at a low magnification closely resemble the "plumose grouping" of beef "stearine."

The following tests were made in order to ascertain what effect recrystallisation had on the form of the crystals from lard, beef and mutton fats. The method of recrystallisation adopted was as follows:—

From 0·1 to 0·15 grm. of the "stearines" A, B and C, Table D, was dissolved in 15 c.c. of ether 0·7175 sp. gr., and the solutions contained in stoppered tubes or "test-mixers" allowed to cool down very slowly to 13° C., the deposited crystals being examined after standing for 24 hours at this temperature, after which the deposits were redissolved in 15 c.c. of ether and treated as before. In

TABLE D.

Lard, Beef, Mutton and Cotton-seed Oil "Stearines" crystallised from Ether Solution.

"Stearine."		Iodine value.	Melting point.	Solubility test (at 12°—13° C.).	
				Petroleum ether (sp. gr. 0·648).	Methylated ether (sp. gr. 0·7175).
				per cent.	per cent.
Lard stearine	A	9·70	64·0	15·60	18·80
Beef stearine (recrystallised)	B	8·20	60·0	—	33·60
Mutton stearine	C	10·10	59·5	20·00	44·20
Beef stearine	D	10·60	58·0	22·40	45·80
Cotton-seed stearine recrystallised several times	E	6·9	59·0	—	—

That the beef "stearine" is more soluble in ether than lard "stearine" is clearly shown by these tests; even after recrystallisation, as in "stearine" B, the solubility was more than twice that of lard "stearine." With petroleum ether, however, the differene in solubility was not so marked. The high iodine values of these "stearines" is remarkable and shows the difficulty of removing the last traces of the unsaturated glycerides: in fact, many crystallisations were required in order to obtain crystals of fixed melting point. An example of this may be of some interest:—

Lard No. 11, Table A (the mixed fatty acids of which contained 19·20 per cent. of stearic acid, as determined by Hehner and Mitchell's method), was chosen for experiment, and 9 c.c. of the melted fat, dissolved in 60 c.c. of ether, and the solution allowed to cool down slowly to 13° C. After the "stearine" had crystallised out, the mother liquor was poured off, and the deposit washed and redissolved in 30 c.c. of ether, 0·720 sp. gr., and treated as before. The melting point of the superfused crystals from the 3rd, 4th and 5th crops was determined, as also the iodine value of the latter. The results are embodied in Table E, which also includes the melting points of the crystals obtained from beef and mutton fats Nos. 16 and 15, Table A, treated in a similar manner.

TABLE E.

	Beef "stearine."		Lard "stearine."		Iodine value.	Mutton "stearine." 2nd m. pt.

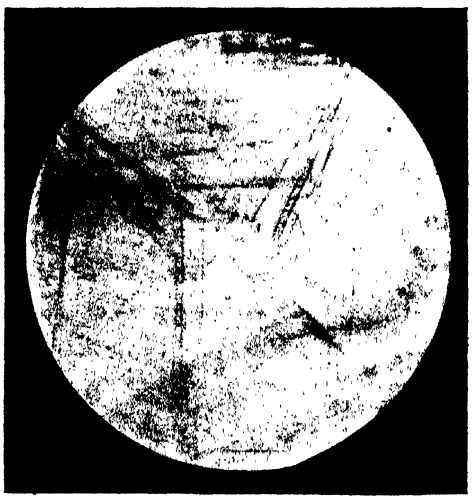

Fig. 2.—Mutton 3rd—380.

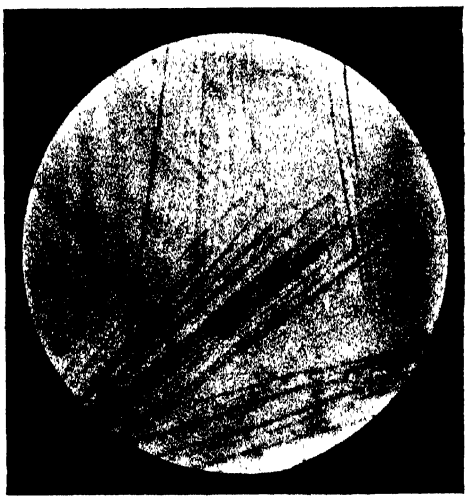

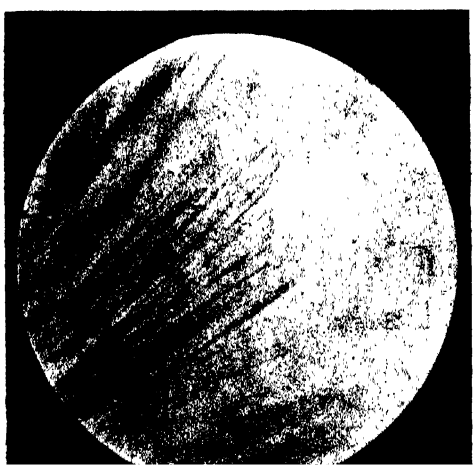

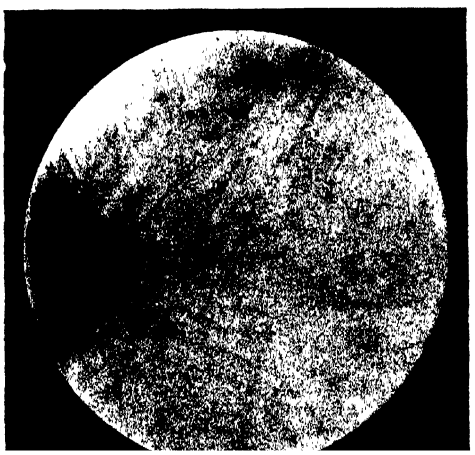

Fig. 5.—Beef 3rd—380.

this way recrystallisation was continued until only a few mgrms. of "stearine" remained.

In examining the crystals, no mountant was employed, the ether being allowed to evaporate after placing the cover glasses, care being taken not to damage the crystals by pressure. The powers employed varied from 30 to 400 diameters, and microphotographs of a number of fields were taken in each crystallisation. Commencing with mutton "stearine" the first crystallisation gave the characteristic curved tufts, the individual crystals showing sharp points at a magnification of 400 diameters. Microphotograph No. 1 shows these groups at 100 diameters.

The "stearine" from the second crystallisation also gave the "plumose groups," but the latter were less curved than in the first crystallisation, while many of the separate crystals showed what may be described as blunt ends or points. In the third crystallisation, however, a great change in the crystalline form was observed, the fine rods having given place to thin plates with, in many cases, oblique terminations as in lard crystals. Microphotograph No. 2 shows such crystals at a magnification of 380 diameters.

A fourth crystallisation was now made, the effect of which was to further develop the lard form of crystals, which could be distinctly seen at 100 diameters and in many fields at as low a power as 30 diameters. Microphotograph No. 3 shows such crystals at a magnification of 380 diameters.

In the case of beef "stearine," the forms observed in the first crystallisation closely resembled those of mutton "stearine," as shown by microphotograph No. 4. The second, and especially the third crystallisation, showed a decided change from the "beef" to the "lard" form (microphotograph No. 5, × 380), while in the fourth the change was very marked.

Here plates with chisel-shaped ends were clearly seen at 100 diameters, the plates being in several fields well formed and arranged in the form of a star, as shown in microphotograph No. 6. Although a large number of such groups was observed, the larger proportion had the "plumose" formation, the individual crystals in the latter resembling narrow lard plates and not the fine-pointed needles obtained from the first crystallisation.

This remarkable change which takes place in the form of the crystals from beef and mutton fats after repeated crystallisation from ether, can, no doubt, be explained by the greater solubility in ether of the particular glycerides giving the "beef" form of crystal, and consequently the ultimate appearance of a less soluble one, which gives the flat plates characteristic of lard.

Under the heading "Examinaton of Lard Crystals separated from Ether" ("Analyst," **21**, page 328), Hehner and Mitchell give the results obtained by the repeated crystallisation of the "stearine" from hard lard. They found that the crystals became more and more needle-like until finally they could hardly be distinguished from beef "stearine" crystals, meaning by the latter, one would suppose, the crystals from a first crystallisation of beef "stearine." After showing how the amount of stearic acid increased with each crystallisation, the authors state that "the form of the beef crystals is solely due to the larger proportion of stearic acid, than can be obtained from a pure lard by a single crystallisation." If that be so, one would expect to obtain finally, after the repeated crystallisation of lard, beef and mutton "stearines," the fine-pointed needles characteristic of a first crystallisation of beef fat. This certainly has not been my experience, as shown in the case of beef and mutton "stearines," while with lard "stearine" I have been unable to confirm the statement made by Hehner and Mitchell. The "stearine" from lards Nos. 11 and 12, Table A, was recrystallised five times by the method previously described, the crystals from each crop being examined under the microscope. While the crystals obtained finally were certainly much narrower than those from a single crystallisation of normal lard, they could not be described as rod or needle like, and fully 80 per cent. of the crystals showed oblique terminations at 100 diameters. The grouping of the crystals was also quite distinct from beef fat.

A series of crystallisations was also made with a mixture of lard and beef "stearines," the quantities employed being 0·200 grm. of each of the "stearines" (A and B, Table D) dissolved in 20 c.c. of ether, 0·7178 sp. gr.

The crystals from the first, second and third crystallisations, when examined at 100 diameters, appeared as large curved tufts, the individual crystals in the latter resembling badly-formed beef crystals; but as recrystallisation proceeded, the form was gradually modified, the crystals becoming less curved and showing at higher magnifications oblique or chisel-ends, while those obtained finally in the twelfth and thirteenth crystallisations were unmistakably lard crystals.

After having tried several methods of crystallisation, using as solvents ether, petroleum ether, fusel oil, &c., I have been led to the following conclusions, with regard to the detection of beef fat in lard.

(1) That it is necessary to employ a much higher power than 100 diameters when examining the crystals from a suspected sample of lard, as the appearance of "plumose" groups at the above power alone, without regard to the form of the individual crystals at a higher magnification, is no proof of the presence of beef "stearine."

(2) That as the "stearine" obtained from beef fat by a single crystallisation is more soluble in ether than the "stearine" from a first crystallisation of lard, it is useless to attempt to eliminate lard "stearine" from a mixture of the two, by recrystallisation, as recommended by Keating Stock.

(3) That as the weight of ether washed deposit (Keating Stock's method) from genuine lard varies, as has been shown, from 5 to nearly 200 mgrms., it is dangerous to draw conclusions either quantitative or qualitative, from such a test.

As for the more general question of the detection of beef fat in lard by means of the microscope, the conclusions to which I have come cannot be better expressed than by quoting Hehner's remarks on the Belfield test ("Analyst," 1902, **27**, 24).

"When cotton-seed or other vegetable oil can be traced, and the iodine value is high, the 'beef form' of crystals may be taken to afford evidence of the presence of beef or mutton fats."

"In the absence of vegetable oil, and with a low iodine value, the Belfield test can at most afford some reason for suspicion, but no trustworthy evidence of adulteration."

New York Section.

ERRATA.

EARTH ALKALI AND ALLIED PEROXIDES.

BY DR. R. VON FOREGGER AND HERBERT PHILIPP.

(*This J., April 16th*, 1906, 298—302.)

In all cases where the words "specific gravity" occur, the word "density" should be read. The authors desire to explain that by the "density," or, perhaps better, the "apparent density" of a powder, is mean the volume which an uncompressed body takes up, with its included air spaces. Thus, to say that calcium peroxide (60 per cent.), of sp. gr. 2·378, has an apparent density of 0·603, implies that 1 c.c. of calcium peroxide, in powder form, weighs 0·603 grm.

1 c.c. of strontium peroxide (85 per cent.) of sp. gr. 3·845, weighs 0·546 grm.; 1 c.c. magnesium peroxide (28 per cent.) of sp. gr. 1·923, weighs 0·615 grm.; 1 c.c. zinc peroxide (50 per cent.) of sp. gr. 3·384, weighs 1·571 grms.

Journal and Patent Literature.

I.—PLANT, APPARATUS, AND MACHINERY.

(*Continued from page* 420.)

High temperatures; Determination of ——. H. v. Wartenberg. D. physikal. Ges. Ber., 1906, 97. Chem. Zeit., 1906, 30, Rep., 138.

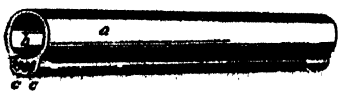
NERNST has proposed making use of chemical equilibrium and the two heat laws for the measurement of high temperatures. As an example of this method the reaction $2H_2O \rightleftarrows 2H_2 + O_2$ has been examined over the range 1400°—2300° C., and the extent of dissociation, *i.e.*, the concentration of hydrogen (x) in the steam, estimated at various temperatures. At the lower temperatures x was determined by analysis of the steam after passing through a glowing tube, the temperature being measured by a thermo-electric junction controlled by the melting point of gold. At higher temperatures, since the reaction products combine on cooling, the partial pressure of the hydrogen was measured directly in the heated furnace by making use of a platinum partition porous only to the hydrogen. Iridium replaced platinum at the highest temperatures, and a Wanner pyrometer, which was compared with a thermo-electric junction, was used to measure the temperature.—F. SODN.

ENGLISH PATENTS.

Furnaces; Impts. in ——. C. B. Burdon, London. From La Soc. Anon. des Proc. Maslin-Theryc, Marseilles, France. Eng. Pat. 9056, April 29, 1905.

IN reversed-draught furnaces in which the air passes downwards through the bed of fuel, the removal of the ashes in the condition of a molten slag is claimed. The slag is maintained in a liquid condition until it reaches the tapping hole, by causing the hot products of combustion to travel with it in the same direction. Further claim is made for enclosing the furnace and slag chamber in a thin refractory casing cooled on the outside, and for water- or air-cooled tubes to form bridges over which the slag flows from the bottom of the bed of incandescent fuel.—W. H. C.

Solvents; Process and apparatus for recovering volatile ——. E. Delhotel, Paris. Eng. Pat. 9441, May 4, 1905.



SEE Addition of May 4, 1905, to Fr. Pat. 344,848 of 1904; this J., 1905, 1169.—T. F. B.

Heating and evaporating liquids by means of steam; Apparatus for ——. D. B. Morison, Hartlepool. Eng. Pat. 10,817, May 24, 1905.

THE claim is for improvements in evaporators such as are described in Eng. Pat. 13,775 of 1900 (this J., 1901, 694). These improvements consist in connecting the outlet and inlet of successive coils by diagonal passages formed in the "header," in providing a separate outlet for the condensed water from each coil into a passage in the "header," and in hanging the "headers" on their supports in such a way that the accumulation of scale has a less binding effect on the hinges.—W. H. C.

UNITED STATES PATENTS.

Retort. R. Ziesing, Cleveland, Ohio. U.S. Pat. 818,070, April 17, 1906.

THE retort, *a*, consists of a retort-chamber, *b*, to contain the material to be treated, and provided with longitudinal ridges, *c,c*, connected by a false bottom as shown. The spaces between the ridges, *c*, serve as air or ventilating passages, and the ridges themselves strengthen the structure of the retort.—W. H. C.

Filter-press. M. Ekenberg, Stockholm, Sweden. U.S. Pat. 818,154, April 17, 1906.

THE claim is for a filter-plate for use in a filter-press, which also claimed, and composed of a number of very thin and flexible sheets of metal disposed face to face; there are means for pressing the sheets together with a pressure capable of regulation. There is also a valve-controlled inlet to the press-chamber for the fluid mixture to be filtered. The material is compressed between the sides by a reciprocating piston, acting at right angles to the laminated sides, through the interstices of which the fluid flows.—W. H. C.

Dryer. C. A. Matcham, Allentown, Pa. U.S. Pat. Reissue 12,474, April 24, 1906.

AN inclined drying cylinder, mounted so that it can be rotated by suitable mechanism, has a portion of its length, nearest the inlet end, enclosed in a chamber heated by the products of combustion from a furnace placed below. The hot gases from the heating chamber are conducted by a flue to the outlet end of the drier, pass through the latter over the material being dried, and escape, along with the vapours given off, into a stack, the lower part of which encloses the inlet end of the rotating cylinder.—W. H. C.

FRENCH PATENTS.

Furnace arranged to utilise special gases, and several applications thereof. L. C. E. Faucheux. Fr. Pat. 360,178, Feb. 15, 1905.

THE furnace of M. Perret (which is constructed of superposed slabs, on which the coal dust to be burned is placed and is caused to descend from one slab to another at each charging operation) may, by suitable regulation of the air inlets, be so worked that the gases of combustion containing nothing but nitrogen, carbon dioxide, and about 0·5 per cent. of oxygen, and may be kept steadily at any desired temperature. The patentee encloses a furnace of this type in a non-conducting material such as kieselguhr, and utilises the hot gases, freed from dust and soot, directly as a source of heat. To ensure the absence of dust and soot, the gases, immediately after charging the furnace, and so long as they contain soot, are passed into the chimney; thereafter they are passed, on their way to the point of application, through large dust-depositing chambers containing metallic gauze, broken coke, flints, &c. The hot purified gases can then, owing to their freedom from oxygen, dust, &c., be brought into direct contact with the substance to be heated. Their application to the concentration of sulphuric acid, and the drying, distillation, torrefaction, &c., of various substances, is described.—H. B.

Soluble substances in grains, pulp, &c.; Apparatus for continuous extraction of —— by means of solvents. E. Bataille. Addition dated Nov. 28, 1905, to Fr. Pat. 319,204 of March 1, 1902 (this J., 1902, 1460).

THE additional claims include the use of a false bottom in the extraction vessel, so that solvents can be heated when required; perforated buckets on the elevator chain raising the material to the drying chamber, so that the solvent may drain off; certain modifications in the arrangement of the extraction and drying chambers; and the suppression of valves in the distributing chamber and the outlet conduit.—C. A. M.

Evaporation of liquids, especially such as are liable to froth excessively; Arrangement for producing the ——. D. Grove and W. Haberland. Fr. Pat. 360,618, Dec. 2, 1905.

THE evaporation is effected from the surface of hollow

discs, mounted on a hollow horizontal shaft, and rotated in a vessel formed like a large hollow disc and partially filled with the liquid. The smaller discs are partly filled with some badly conducting body such as an oil, and are rotated so slowly that the oil remains in the lower halves of the discs, which are partially immersed in the liquid to be evaporated. The heating agent, *e.g.*, steam, is introduced into the upper halves of the discs, through the hollow shaft. When the shaft is rotated, a portion of the liquid adheres to each disc, and it is only the liquid adhering to the upper half of each disc that becomes heated; the lower parts of the discs being filled with the badly conducting material, impart but little heat to the main body of the liquid, which does not enter into ebullition, and consequently violent frothing is avoided.—W. H. C.

Liquids or mixtures of liquids; Process for rendering homogeneous mechanically ——. Deutsche Homogenisiermasch.-Ges. First Addition dated Dec. 8, 1905, to Fr. Pat. 354,943, June 5, 1905 (this J., 1905, 1162).

Before passing through the pulveriser, the liquids to be rendered homogeneous are thoroughly mixed in an agitator with vertical beaters, the mixer being surrounded by a jacket through which a heating or cooling medium can be circulated. The mixture is then passed through a system of crossed spiral tubes to the pulveriser, which is also jacketed in order that the liquids may be heated or cooled during pulverisation by circulating a heating or cooling agent through the jacket.—W. H. C.

Indicator and regulator of temperature; Thermo-electric ——. Soc. les Etablissements Poulenc Frères. Fr. Pat. 360,258, Dec. 9, 1905.

The temperature of a furnace is automatically regulated by the action of a pyrometer which causes a deflection of a galvanometer, such deflection acting in conjunction with an auxiliary circuit, serving as a relay, to alter the position of the damper in the flue of the furnace. The temperature of the furnace can in this way be maintained constant within two desired limits.—R. S. H.

Filtering or separating liquids from solids or matter from impurities; Apparatus for —— and for similar uses. The Clayton Aniline Co., Ltd. Fr. Pat. 360,533, Dec. 16, 1905. Under Int. Conv., June 7, 1905.

See Eng. Pat. 11,957 of 1905; this J., 1905, 1003.—T.F.B.

Drying-drum with central tube. L. Boltri. Fr. Pat. 360,851, Dec. 22, 1905. Under Int. Conv., Dec. 28, 1904, and Aug. 19, 1905.

The apparatus consists of a drum having an inner, coaxial, central tube, and mounted on an axis so that it can be rotated. A longitudinal slot, or opening, is formed on one side of the drum and can be closed by a gauze plate. The apparatus is charged by bringing the opening uppermost and filling in the material to be dried. The gauze plate is then placed over the opening and the drum is turned through half a revolution, the opening being now underneath. Warm air, introduced by a pipe through the upper part of one end of the drum, passes downwards through the contents and escapes through the gauze at the bottom. The presence of the central tube causes the heated air to be distributed evenly through the material, and very little "dead space" is formed.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 422.)

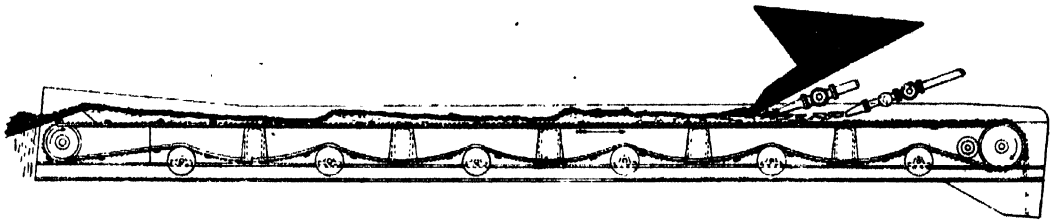
Coal; Spontaneous ignition of ——. V. B. Lewes. J. Gas Lighting, 1906, **94**. 33—34.

In the spontaneous ignition of coal stored in bulk, the oxidation of the pyrites present only plays a very subsidiary part, the chief factor being the surface condensation of the oxygen in the pores of the coal, and the action of the condensed gas in effecting the oxidation of the hydrocarbons present in the coal. Whilst sufficient ventilation to prevent any considerable increase of temperature within the mass is effective in preventing ignition, it is practically impossible to maintain this condition in large coal stores or in a cargo on board ship, where usually only enough air enters to lead to dangerous heating. The recent suggestion to thoroughly wet the whole mass of coal is likewise impracticable, owing to the great increase of weight brought about if sufficient water is added to be effective, and too small a quantity of water only accentuates the danger.

The extinction of coal-fires which break out on board ship is a matter of extreme difficulty, owing to the frequent impossibility of getting water to the exact seat of the fire, and to the formation of hydrogen and carbonic oxide by the action of the steam on the incandescent fuel, which results in the production of an explosive mixture in the coal bunkers. In order to extinguish at an early stage any fire which may break out, the author recommends that small cylinders of liquid carbon dioxide should be buried in different parts of the mass of coal during loading, the valve of the cylinder being open, but the delivery tube closed with fusible alloy melting at 93° C. If the temperature of the coal at any time rises above this point, the alloy fuses, and the liquid carbon dioxide is volatilised, causing great local cooling, and the cold heavy gas, which does not support combustion remains for some considerable time in contact with the coal, preventing further combustion.—H. G. C.

Furnace gases; Hydrocyanic acid in ——. K. Jurisch. Chem.-Zeit., 1906, **30**, 393—394.

The author has found small quantities of prussic acid in the boiler house furnace gases of a factory, the working conditions of which are detailed. For its detection, the gases passing upwards were met by a 25 per cent. solution of caustic soda, containing freshly precipitated ferrous hydroxide, which was sprayed downwards; 15 litres of solution were used, descending in 15 minutes, and then being pumped up again. After 4000 cb. m. of the gases had passed through in this manner, the solution was removed, boiled and tested for ferrocyanide in the usual way. A blue colour was obtained, and after long standing, a precipitate of Prussian blue.—F. Sodn.



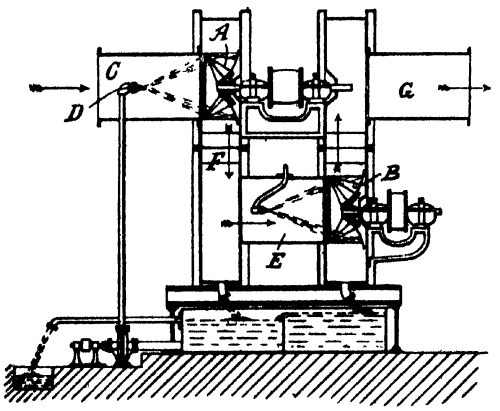
English Patents.

Filtering liquids containing fine coal or other mineral or like substances; Apparatus for ——. C. Craig, Dewsbury and W. and G. K. Craig, Sacriston. Eng. Pat. 9464, May 5, 1905.

The apparatus consists of a vertical cylindrical tank with a liner of metal gauze or perforated plate, and several vertical perforated tubes rising from the bottom of the tank. The liquid to be filtered is fed into the tank by a rotating distributor, actuated by the liquid itself on the principle of the "reaction wheel," or by a conical distributing table. The liquid passes through the perforations and is drawn off by suitable pipes, and the solids which collect in the tank are removed from time to time through openings in the bottom.—W. H. C.

Washing of coal and other minerals; Apparatus for the ——. J. Shaw, Pontefract. Eng. Pat. 13,018, June 23, 1905.

The apparatus consists of an inclined trough in which works an endless conveyor constructed of transverse slats riveted to a pair of endless chains, and having cross-dams bolted to the slats at suitable intervals. Above the conveyor is fixed a series of inclined flaps having their free ends resting on the transverse slats, and forming on the upper surface of the conveyor a series of receptacles. The coal is fed on to the upper end of the conveyor, and is carried downwards by a current of water from a nozzle. The heavier particles (mineral impurities, &c.) collect in the receptacles formed by the flaps, whence they are carried upwards, against the current of water, by the conveyor, and after being further washed by water from a second nozzle, are discharged at the upper end of the conveyor. The lighter particles of coal are carried by



the water over the inclined flaps, and are discharged from the lower end of the conveyor on to a draining-plate.—W. H. C.

Burners for liquid fuel; Impts. in ——. N. and H. Fraser, Arbroath, N.B. Eng. Pat. 23,351, Nov. 14, 1905.

THE burner comprises a coiled vaporising pipe, which is situated over the burner proper and receives the fuel supply; a vapour chamber, which receives the vapour from the pipe and prevents "back-firing," after the manner of the air vessel of a pump; and a nozzle which directs the vapour from the chamber into a horizontal air-mixing tube, which tube admits the mixture of air and vapour tangentially into an inverted conical vessel, opening beneath a domed, perforated plate. The mixture of air and vapour, on entering the conical vessel, swirls in a circular and upward direction within it, becoming well mixed and evenly distributed under the domed plate, and ignites after passing up through the perforations in the latter.—H. B.

Gases; Method whereby furnace and other —— may be completely and rapidly freed from dust and other foreign matters held in suspension therein; and apparatus therefor. P. Kestner, Lille. Eng. Pat. 9548, May 5, 1905.

THE gases enter the apparatus by the pipe, C, and in the case of cold gases, steam, or in the case of hot gases, water

which is converted into steam, is injected through the nozzle, D. The mixture then passes through the "draught producing, atomising fan," A, and the pipe, F, to the condensing chamber, E, where it is rapidly cooled and the steam condensed by cold water injected through the nozzle shown. The particles of dust are thoroughly wetted, and fall with the condensed water, whilst the purified gas passes on through a second fan, B, where further condensation takes place, to the outlet, G.—W. H. C.

Gases; Separation of dust from ——. B. H. Thwaite, London. Eng. Pat. 23,378, Nov. 14, 1905.

THE claim is for improvements in the method of removing dust from gases described in Eng. Pat. 6837 of 1898, and comprises the use of two or more separate electrostatic dust-separating chambers, arranged in series and provided with by-pass valves; and the combination of electrostatic and centrifugal dust separators.—W. H. C.

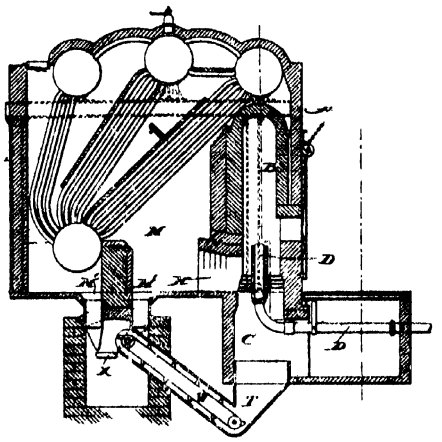
Vaporisers for combustible liquids for use with explosion motors. L. and T. Gautreau, Paris. Eng. Pat. 995, Jan. 13, 1906. Under Int. Conv., Jan. 14, 1905.

THE vaporiser, which is adapted for use with slightly volatile combustible liquids such as heavy petroleum, mineral oils, alcohol, &c., consists of a jacketed tube, one end of which is connected to the suction port of the motor, whilst the other receives the mixture of air and combustible liquid, the hot waste gases from the motor flowing through the jacket of the tube and heating it sufficiently to vaporise the liquid. Within the main jacket the tube is surrounded by a smaller, independent jacket, having inlet and outlet ports communicating with the air; within one of these ports, when starting the motor cold, a blowpipe burner or the like is lit, and is kept burning until the vaporiser is sufficiently hot to maintain the supply of vapour to the motor. The two jackets being independent, the operation of the starting burner does not interfere with the circulation of the hot waste gases from the motor.—H. B.

Gas producers; Improved apparatus for automatically sustaining the suction influence in suction ——. B. H. Thwaite, London. Eng. Pat. 7904, April 13, 1905.

ON a hollow base, which communicates on the one hand with the gas producer and on the other with the gas engine, are erected several pipes, the upper ends of which enter a hollow chamber; from the latter a circular bellows-like device is suspended, which remains extended to its full length when the gas engine is not sucking the gas, but is capable of being drawn up at its lower end when the bellows contract during the suction. At each suction-stroke of the engine the lower end of the bellows (which is suitably weighted) is drawn up; when the suction stroke ceases, the bellows again expand, and the suction is thus maintained in the producer during the intervals between the suction strokes of the engine. A non-return valve is provided in the pipe leading from the hollow base to the gas engine.—H. B.

Gas producers: Impts. in ——. Maschinenfabrik und Mühlenbauanstalt G. Luther A.-G., Brunswick, Germany. Eng. Pat. 1295, Jan. 17, 1906. Under Int. Conv., Dec. 13, 1905.



To render practicable the use of very wet fuel in a producer operating with an upper and a lower combustion zone, a hollow body, having apertures on all its free sides, is arranged within the producer so as to extend across the latter from wall to wall above the upper combustion zone. The upper sides of the body are roof-shaped, and so steeply inclined that fuel cannot remain sticking to them, but must slide down. Air enters the body through inlets at each end, and gases from the combustion zone also enter it through the apertures in its sides, burning with the air within it and thus expelling the water from the downwardly moving fuel. The steam generated may either be led downwards through suitable channels to the lower zone of combustion, or be allowed to escape through a chimney.—H. B.

United States Patents.

Fuel from peat; Process of producing —— by means of the electric current. J. B. Bessey, London. U.S. Pat. 817,899, April 17, 1906.

See Eng. Pat. 17,497 of 1904; this J., 1905, 322.—T. F. B.

Burning pulverised fuel and other substances; Process of and furnace for ——. A. M. Robeson, Johannesburg, and C. A. Bettington, Boston, Mass. U.S. Pats. 817,989 and 817,990, April 17, 1906.

A mixture of powdered fuel and air is blown through the pipe, D, into the vertical combustion chamber, B. The mixture burns and rises to the upper closed end of B, and is then deflected downwards, any particles of burning fuel being held in suspension by the rush of the incoming mixture. The products of combustion escape through the passage, H, into the heating chamber, M. The ashes are deposited in the chamber, C, and collect in the space, T, from which they are removed by the elevator, W, and are finally deposited in the space, X, along with any flue dust from the slides, M'. W. H. C.

Combustion; Method of ——. O. Bender, Treptow, Germany. U.S. Pat. 818,221, April 17, 1906.

See Fr. Pat. 351,210 of 1905; this J., 1905, 838.—T. F. B.

Gas; Apparatus for producing ——. J. S. Smith, Chicago, Ill. U.S. Pat. 817,279, April 10, 1906.

In a gas-producing apparatus, an imperforate "breaker-wall" is located within the generating chamber, and its resisting-surface is maintained in a uniformly highly heated condition. Means are provided to direct the gas-producing materials against the resisting-surface with forcible impact and at a decomposing heat whereby the initial generation of gases takes place. Additional steam may be supplied to the generating chamber in the path of discharge of the gases generated and at a temperature ensuring decomposition. Heavy hydrocarbons and other unvaporised materials are removed from the fixed gases in suitable extractors, and the gases, after drying, delivered under pressure into stationary or movable storage vessels.—R. L.

Gas; Method of producing ——. J. S. Smith, Chicago, Ill. U.S. Pat. 817,280, April 10, 1906.

Fixed gas and lubricating oils are simultaneously produced from crude petroleum by heating the latter, mixing it with an excess of steam, and passing it in the presence of air, into a generating chamber, wherein it is discharged violently and continuously against a resisting surface "at a self-sustained heat of decomposition." The resulting gases, the ash of combustion, and the excess of steam are conducted in a swiftly moving current out of this chamber and condensed hydrocarbons are discharged by their gravity into an external receptacle, whereby the volatile portion of the oil is recombined with the fixed gases and the heavy hydrocarbons are withdrawn in liquid form. The heat of decomposition in the generating chamber is controlled by the supply of steam. The production of gas and withdrawal of liquid are constant and continuous.—R. L.

Gas making apparatus. L. P. Lowe, San Francisco, Cal. U.S. Pat. 817,647, April 10, 1906.

The apparatus for generating gas consists of a casing divided into two chambers connected at the bottom by a partition wall with a bottom opening. Arches are built on the bottom of each chamber, and carry loosely-piled refractory material. Air and oil can be admitted at the top of the first chamber, another oil inlet being provided at the bottom of one of the chambers. Steam is supplied at the top of the second chamber, which also carries a stack which may be closed with a lid. The gas outlet is at the top of the first chamber, whilst the coke is withdrawn from the bottom of both chambers through suitable openings.—R. L.

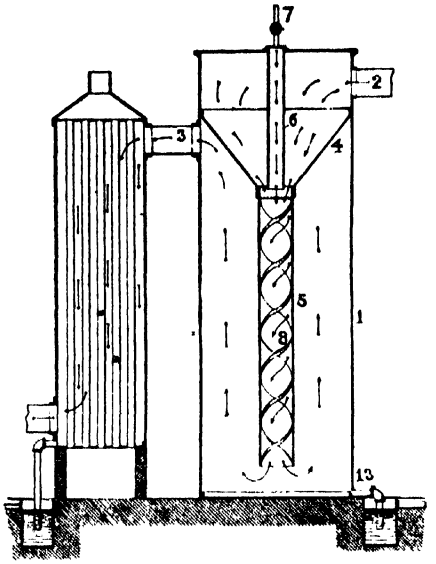
Gas; Apparatus for making ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 817,648, April 10, 1906.

The apparatus for making gas comprises a casing in which a partition wall extends from the bottom to a point near the top, forming two compartments. Two arches divide these compartments into four chambers, which are filled with loosely piled refractory material. A flue and an air-blast are "selectively connected with the bottom of each lower chamber." An oil pipe discharges into the upper chambers; a steam pipe and gas outlet pipes are provided at the top of each lower chamber.—R. L.

Gas; Apparatus for manufacturing and delivering ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 817,649, April 10, 1906.

In combination with an apparatus for manufacturing gas, the gas is delivered to a compressor through a service pipe which has a branch pipe supplying an engine by which the compressor is operated. The flow of gas to the engine can be controlled by a valve, which is regulated by the pressure in the service pipe leading to the compressor with which it is connected.—R. L.

Gas purifier. L. P. Lowe, San Francisco, Cal. U.S. Pat. 817,650, April 10, 1906.



A purifier with inlet and outlet for the gas to be purified is provided with a series of trays or boxes to support the purifying material while allowing free passage to the gas. Several rows of stationary bars extend into the purifying material to disintegrate the same by their motion due to changes of temperature.—R. L.

Gas producer. F. G. Hobart, Beloit, Wis., Assignor to Fairbanks, Morse and Co., Chicago, Ill. U.S. Pat. 817,853, April 17, 1906.

An annular vaporising chamber is formed round a fuel storage and feeding hopper at the top of the producer, a space being left all round the hopper between it and the inner circular wall of the vaporiser, which has ribs that project into this space. The cover of the vaporiser extends over the annular space and is attached to the sides of the hopper. Valved poker-holes in that part of the cover which is above the annular space, and openings into the vaporiser through which the steam can pass to the lower part of the producer, are provided.—W. H. C.

Gas-purifier. E. C. Jones, San Francisco, Cal., and S. T. Wellman, Cleveland, Ohio. U.S. Pat. 818,891, April 24, 1906.

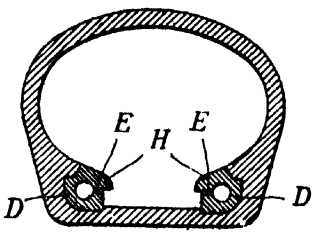
The gas to be purified enters the apparatus, 1, through the pipe, 2, and, after being mixed in the conical chamber, 4, with vapour introduced through the pipes, 7, and 6, is injected along with the vapour into the tube, 5. The mixture passes down this pipe, its passage being impeded by the spiral baffles, 8, and the purified gas then passes

upwards, as shown by the arrows, to the outlet, 3. Any condensed liquid flows away through the pipe, 13, which is sealed as shown.—W. H. C.

French Patents.

Compounds for heating; Agglomerated —— and process for manufacturing them. A. Andrieu and P. Giraud. Fr. Pat. 360,861, March 13, 1905.

Crocidolite, an asbestos-like mineral, is soaked in 15 per cent. of its weight of milk of lime and dried. It is then mixed with coal-dust and agglomerated either by heat or by pressure, after addition of 5 per cent. of magnesium chloride. The material is then impregnated with heavy oil, petroleum residues, or tar and dried on a bed of powdered alunnite and manganite. The dried mixture when burnt is said to afford an easy means of rapidly raising steam.—W. H. C.



Briquettes made with an agglutinant soluble in water; Process for rendering unalterable in the air ——. R. Bock. First Addition, dated Nov. 18, 1905, to Fr. Pat. 325,708, Oct. 27, 1902 (this J., 1903, 736).

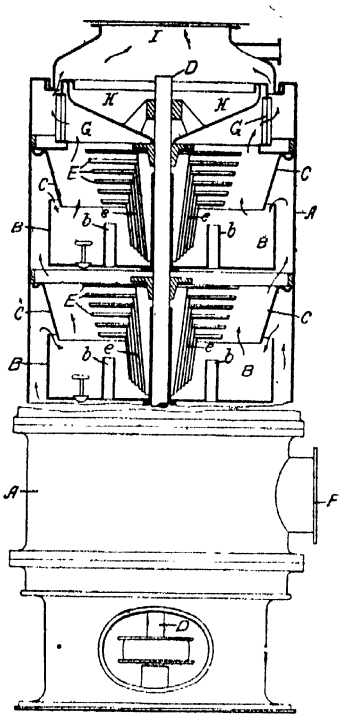
The addition relates to a method of carrying out the process described in the original patent, and consists in heating the coal, before it is briquetted, to a temperature slightly higher than that to which the briquettes are subsequently heated to carbonise the agglomerant. The object of the preliminary heating is to prevent the evolution of gas during the carbonisation of the agglomerant. W. H. C.

Gas-retort furnace. P. V. Parsy. Fr. Pat. 360,070, Feb. 11, 1905.

The retort setting is divided into a number of vertical chambers, each chamber containing only one vertical row of retorts. Each pair of chambers is heated by means of a separate generator and recuperator, which are situated upon the same floor level as the retorts and occupy a vertical compartment separating the one retort-chamber from the other. The generator gases and secondary air from each generator and recuperator are distributed between the two corresponding retort-chambers, entering the latter through orifices at the top, passing with downward combustion over one side of the retorts, and flowing up the other side to outlets at the top. These arrangements are designed to ensure the uniform heating of all the retorts in the bench, and to obviate the obstruction of the gas orifices, which is sometimes caused by falling particles of refractory material, &c., when the orifices are situated below the retorts.—H. B.

Gas or steam; Device for introducing —— into the interior of gas retorts. Stettiner Chamotte-Fabrik A.-G. vorm Didier. Fr. Pat. 360,032, Dec. 2, 1905

The channels for the introduction of steam or gas into the interior of the retort are in the form of tubular conduits made of refractory material fitted removably into the retort; as, for example, in the cross-sectional illustration given, wherein the tubular conduits D, provided with outlets, E, for the steam or gas (the overhanging projections, H, serving to keep the coal from blocking the outlets) are keyed into the retort in such a manner that they may easily be withdrawn if necessary.
—H. B.



Gas producer with downward combustion. L. A. David. Fr. Pat. 360,058, Dec. 4, 1905.

The producer, which rests in a water-sealed ash-pan, is surrounded by a deep bell, suspended over it from above. Whilst the producer is in operation, the air supply flows up the annular space between the bell and the producer, taking up the heat radiated from the exterior of the latter, and enters the combustion chamber at the top. By lowering the bell until it rests upon the top of the combustion chamber, the latter can be closed, and by raising it until its lower edge is above the top of the producer, fresh fuel may be charged in. The upper portion of the bell may be formed as a reservoir for liquid, which may be allowed to drop into the fuel in the combustion chamber; or the heat may vaporise the liquid in the reservoir, the vapours being directed downwards into the incandescent fuel. The producer has two superposed, horizontal, circular grates, which can be rotated in opposite directions.
—H. B.

Gases; Process and apparatus for the [centrifugal] purification of ——. A. Elsenhans. Fr. Pat. 360,341, Dec. 12, 1905. Under Int. Conv., Dec. 13, 1904.

The gas to be purified and the washing liquid are caused to pass in the same direction from the centre to the periphery of a centrifugal purifier, comprising a series of concentric annular spaces in which the liquid is whirled and splashed about on its way to the periphery, being thus brought into intimate contact with the gas. The apparatus described consists of two horizontal discs, bolted together at a suitable distance apart, on the opposed surfaces of which are attached several concentric annular partitions or baffles, those depending from the upper disc alternating with those rising from the lower disc, and none of them extending across the whole way to the opposite disc. The discs, which are provided centrally with inlets for the gas and liquid, are rotated at high speed within a casing which has gas and water outlets at its periphery. As all the annular partitions incline outwards towards the periphery, the liquid is both whirled round and projected violently from the free edge of each partition against the inner side of the next, and so on in a zig-zag course to the periphery, being thoroughly broken up and brought into intimate contact with the gas. Various modified forms of the discs and partitions are described
—H. B.

Gases or vapours and liquids [washing gases]; Apparatus for obtaining reciprocal action between —— W. Feld Fr. Pat. 360,373, Dec. 12, 1905.

The apparatus consists of a number of superposed basins, or trays, B, which contain the liquid and which are provided with overflow pipes, *b*, and with inverted truncated cones, C, whose lower edges dip below the rims of the basins, B, the whole being enclosed in the casing, A. A number of concentric tubes, *e*, which terminate above in the superposed discs, E, are attached to and rotated by the central shaft, D, and cause the liquid contained in B, to rise between the tubes, *e*, and to be dispersed, by centrifugal force from the discs, E, in the form of spray which falls back into the basins, B. The gas enters the apparatus at F, and following the path indicated by the arrows, passes through the falling spray of liquid in each chamber, and rises to the top, where it is compelled by the partition, H, to pass through the gauze filters, G. It is here deprived of any spray which it may have carried forward, and finally escapes from the apparatus through I. —W. H. C.

Illumination by petroleum, benzine and alcohol; Compound of chemicals giving greater brilliancy to — —. E. S. Mathon. Fr. Pat. 359,798, Nov. 27, 1905.

A mixture of about 95 parts of magnesium sulphate, four parts of spermaceti, and one part of paraffin wax, all in powder, is "dissolved" in the petroleum or alcohol in order to give greater brilliancy to the light obtained.—W.H.C.

Mantles; Process of treatment of fabrics or threads for the manufacture of incandescence — —. A. I. van Vriesland. Fr. Pat. 359,945, Nov. 29, 1905.

The fabric or the thread is treated wholly, or at parts, with acids or alkaline solutions sufficiently strong to produce a contraction of the material, for the purpose, *e.g.*, of rendering the knitted stocking narrower when the meshes are too wide, or for strengthening the thread when the latter is too thin, or for strengthening the head or producing local constrictions, &c.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 423.)

Petroleum; Notes on the chemical examination of ——. K. Charitschkow. Westnik shirow, 1906, **7**, 14; Chem. Zeit., 1906, **30**, Rep. 142.

The examination of stored petroleum from Grosny by the Dehnstedt-Geisler (aniline) reaction revealed the presence of sulphuric esters. The amount varied inversely with the quantity of acid used in the acid-refining process, being equivalent to 0·00227 grm. of sulphur trioxide per litre with 0·5 per cent. of acid, but only 0·00067 grm. when 2 per cent. of acid had been used. These compounds are undesirable, since they lead to the charring of the wick when the oil is burned in lamps, but how they originate and in what form is still undetermined. Sulphur also reduces the illuminating power of the oil, even when present in but small amount. A simple method of determining the sulphur content is by distilling the oil from metallic potassium, any sulphur present combining with the metal. The author considers that the sulphur content should be taken into account when judging the purity of Russian lamp oil, and he approves Weber's suggestion that the percentage of unsaturated hydrocarbons should also be determined.—C. S.

Paraffins; Transparent and milky ——. H. Mittler and R. Lichtenstern. Chem. Rev. Fett- u. Harz-Ind., 1906, **13**, 104–105.

"Milkiness" in paraffins is attributed by the authors, not to differences in the melting points of the different constituents as asserted by Neustadtl (this J., 1906, 171), but to the presence of paraffin oil. Thus a sample of milky paraffin was found by Holde's method to contain only 94 to 96 per cent. of solid paraffin, the residue, isolated by extraction with alcohol-ether, consisting of paraffin oil. This conclusion was confirmed by experiments with paraffins of high and low melting points, which were rendered "spotted" or "milky" by the addition of 0·5 to 3 per cent. of paraffin oil. The addition of 0·2 to 0·3 per cent. had little, if any, effect. Evidence against Neustadtl's view was that transparent paraffins of the most divergent melting points (*e.g.*, 57° and 42° C. could be mixed in equal proportions without any appreciable effect on the transparency, although, in some cases, a bluish "cast" was produced.—C. A. M.

Petroleum production of California. For. Off. Ann. Series, No. 3564.

According to the figures prepared by the California Petroleum Miners' Association, the production of oil in California in 1905 was 35,671,000 galls., as against 28,476,025 galls. in 1904, 24,337,828 galls. in 1903, and 13,973,500 galls. in 1902. The Kern River district continues to be the largest producer, and is credited with 14,000,000 galls. in 1905, followed by Coalinga with 8,869,000 galls., and Santa Maria and Lompoc with 5,300,000 galls. There has been a large increase in the number of wells, and sufficient drilling operations are proceeding to insure a further increase of production for 1906. The greatest activity in drilling is noted in the vicinity of Santa Maria and Lompoc, where 42 new wells are being drilled. The total number of producing wells is 2,116; wells being drilled, 123; and new derricks, 52.

The heavy shrinkage in the consumption of coal must not be taken as an indication that the fuel demands of California have been less than in 1904. This deficiency has been more than made good by the output of fuel oil, which has increased by over 7,000,000 barrels as compared with 1904. The amount of crude oil exported during the year is estimated at 800,000 barrels, the bulk of which was sent to China and Japan by a line of tank steamers recently established by the Standard Oil Company, which sail under the British flag. The railroads

of the State are believed to be consuming about 15,000,000 barrels annually, and the low price at which it is being produced for transportation and manufacturing purposes has proved of inestimable advantage to all lines of commerce. The Standard Oil Company's pipe line from Bakersfield to Point Richmond is practically a failure. The gravity of California oil is such that pumping, heating and dilution sufficient to make it flow freely have not been found practical. The company is, therefore, resorting to water transportation, and is erecting a plant for building steel barges.

The Union Oil Company of California has developed a plan to extend its business by entering the markets of the Atlantic seaboard and Europe with crude and refined petroleum oils. Transportation facilities were the great drawback, but the difficulty has been solved by a concession to run a pipe line across the Isthmus of Panama, which has been granted to the company. Shipments of the necessary pipe have already commenced from the Eastern States, and it is expected that the line will be completed by July 1, 1906. The company has recently purchased six additional steamers which will be used in the transportation of oil, and the refinery on the Bay of San Francisco is being greatly enlarged to supply the increasing demands.

The six tank steamers owned by the company and plying in Pacific waters have a joint carrying capacity of 6,000,000 galls. It is arranged that five of these shall carry oil direct from Santa Barbara and other fields in Southern California to Panama whence the cargoes will be pumped across the Isthmus into the holds of two tank steamers for conveyance to New York and other Atlantic ports. [T. R.]

FRENCH PATENTS.

Coke-ovens; Impts. in regenerative ——. E. Coppée. Fr. Pat. 359,888, Nov. 28, 1905. Under Int. Conv., July 3, 1905.

Two regenerator chambers, common to the whole battery of ovens, communicate at either end with a valve chamber. The hot gases from the ovens enter one of these valve chambers, pass through and heat one of the regenerators and then to the second valve chamber, by which they are delivered to the place where they are utilised. At the same time air enters the second valve chamber, passes through the other regenerator, becomes heated and enters the first valve chamber. It then passes to a conduit by which it is distributed to the ovens. At appropriate intervals the valves are reversed, but, as the air always enters through the same valve chamber, the direction in which the gases and air pass through the oven flues remains the same.—W. IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 424.)

Catalytic substances; Influence of —— on the substitution of aromatic rings. K. Holdermann. Ber., 1906, **39**, 1250—1258.

ANTHRAQUINONE and its derivatives on sulphonation yield β-sulphonic acids almost exclusively, unless mercury is present, when the α-derivatives only are obtained (see Iljinsky, Ber., 1903, 4194; R. Schmidt, Ber., 1904, 66). The author sulphonated and nitrated various benzene, naphthalene, and anthraquinone derivatives to see whether this important technical method for the preparation of α-anthraquinonesulphonic acids was capable of general application. He finds that the catalytic action of mercury is confined to the sulphonation, and in a lesser degree to the nitration of anthraquinone derivatives. With other substances the course of the reaction is not affected by the presence of mercury or its salts, except in the case of aniline and sulphuric acid, where an addition of a small quantity of mercuric sulphate at 180° C. caused "charring" and a violent ebullition of sulphurous acid. The effect of the mercury salt in this case is to greatly further the oxidising action of the acid and to prevent sulphonation, just as in the well-known technical preparation of phthalic acid by oxidising naphthalene with fuming sulphuric acid.—H. L.

Tetramethyldiaminobenzophenone; Nitro-derivatives of ——. A. Kliegl. Ber., 1906, **39**, 1266—1275.

THE author shows that the mono and dinitro-derivatives of Michler's ketone obtained by Nathanson and Müller (see Ber., 1889, 1883), and Grimaux (see Bull. Soc. Chim., 1898, 609), respectively, are 3-nitro- and 3.3′-dinitro-4.4′-tetramethyldiaminobenzophenone. The orientation of the nitro group is thus determined by the carbonyl group. As nitration is carried out in the presence of a large quantity of concentrated sulphuric acid, Grimaux had wrongly assumed that the nitro groups entered the ring in the meta position to the amino groups, in accordance with Noelting and Collin's rule (see Ber., 1884, 261). By reducing the above mononitrotetramethyldiaminobenzophenone with stannous chloride and hydrochloric acid in the cold, 3 amino-4.4′-tetramethyldiaminobenzophenone, m. pt. 139° C., was obtained. The acetyl compound, m. pt. 153·5° 154·5° C., on reduction with zinc and hydrochloric acid in the cold yielded 3-acetamino-4.4′-tetramethyldiphenylcarbinol, m. pt. 145·5°—146° C. These substances were shown to be quite distinct from the corresponding *m*-substituted products, which were prepared for comparison. Thus 2-acetamino-4.4′-tetramethyldiaminobenzophenone obtained by oxidising 2-acetamino-4.4′-tetramethyldiaminodiphenylmethane with chloranil melts at 162° C. On saponification it yields 2-amino-4.4′-tetramethyldiaminobenzophenone, m. pt. 205·5° C., and on reduction 2-acetamino-4.4′-tetramethyldiphenylcarbinol, m. pt. 165° 169° C. H. L.

Gallacetophenone; Condensation derivatives of ——. H. Rupe and L. Veit. Zeits. f. Farben-Ind., 1906, **6**, 101—105.

CONDENSATION derivatives of gallacetophenone have been previously prepared and described by Leontjeff and one of the authors (this J., 1899, 30). The research has been continued by the present authors with the object of determining the chromophoric influence of certain groups in their molecules on compounds of the same class. To this end the following compounds were prepared:—*o-*, *m-*, *and p-Nitrobenzylidene-gallacetophenones*, $C_6H_2(OH)_3.CO.CH:CH.C_6H_4.NO_2$, crystallising respectively in greenish yellow, pale yellow, and golden-yellow needles, of m. pts. 212°, 94° and 138° C., obtained by the action of dry hydrochloric acid gas on mixtures of each of the three nitrobenzaldehydes and gallacetophenone in alcoholic solution. *Meta- and para-nitrobenzal-di-gallacetophenones*, $[C_6H_2(OH)_3.CO.CH_2]_2:CH.C_6H_4.NO_2$,

formed by condensing *m*- and *p*-nitrobenzaldehydes with triacetyl-gallacetophenone and hydrolysing the resulting products, crystallise respectively in yellow and pale yellow needles, melting with decomposition at 220°—230° and 212° C. Attempts to prepare, from gallacetophenone and protocatechuic aldehyde, a compound of the formula $C_6H_2(OH)_2.CO.CH:CH.C_6H_3(OH)_2$, resembling in constitution Maclurin, $C_6H_2(OH)_3.CO.C_6H_3(OH)_2$, were unsuccessful, but its methylene derivative:

$$(HO)_2C_6H_2.CO.CH:CH.C_6H_3:O_2CH_2$$

was obtained by condensing, in alcoholic solution by means of dry hydrochloric acid, triacetylgallacetophenone (2 parts) and piperonal (1 part) and hydrolysing the resulting compound by pouring the solution upon a mixture of ice and water, collecting the crystalline mass which separates and boiling it with alcohol. The product, *methylene - 3.4 - dioxybenzylidene - gallacetophenone*, is insoluble in water, but readily soluble in alcohol, toluene and benzene, from the last of which it crystallises in golden-yellow needles (m. pt. 208° C.). Concentrated sulphuric acid dissolves it with a deep red colour. Its dyeing powder is remarkable, 1 per cent. of it sufficing to dye alumina-mordanted cotton an intense orange, or iron-mordanted cotton black (or reddish-brown? see below), or chrome-mordanted wool brownish-orange. It also dyes from a slightly acid bath unmordanted wool in a pale yellow colour. After repeatedly crystallising it from alcohol, the dyeing power becomes reduced, presumably owing to the separation from the methylene-compound of the free dihydroxy compound formed by its decomposition, with which it is admixed. As, however, the m. pt. of the principal product remains unaltered after this treatment, it would seem that the quantity of the dihydroxy compound thus formed is very minute. The behaviour in dyeing of these compounds, in comparison with that of gallacetophenone, is shown in the following table:—

	On cotton mordanted with		On wool mordanted with
	Iron (3 per cent of dyestuff).	Chrome (3 per cent. of dyestuff).	Chrome (1 per cent. of dyestuff).
Gallacetophenone ("Alizarin Yellow C," B A S F) ...	Grey	Pale olive	Yellowish-olive
o-Nitrobenzal-gallacetophenone	Dark olive	Deep orange	Dull olive
m- " "	Greyish-black	Dull orange	Dull olive
p- " "	Black	Yellowish-green	Olive
p-Nitrobenzal-digallacetophenone	Greyish-black	Yellow	—
Methylene-3.4-dioxybenzal-gallacetophenone	Reddish-brown	Bright orange	Deep yellowish-brown

—E. B.

Amines; Introduction of the CH_2OH and CH_2 groups into primary aromatic ——, and the preparation of imine bases. E. Orloff. J. russ. phys.-chem. Ges., 1906, **37**, 1255—1269. Chem. Centr., 1906, **1**, 1413—1416.

THE imino base,

$$(6)\ (CH_2OH)C_6H_3{<}^{NH(1)}_{CH_2(2)},$$

from sodium formanilide and formalin (this J., 1905, 326), is soluble in glacial acetic acid, and on heating to 140° C. is converted, without melting, into the brown compound,

$$H_2C{<}^{HN}{>}C_6H_3.CH_2.O.CH_2.C_6H_3{<}^{NH.}_{CH_2}$$

The imino base from β-formonaphthalide yields an analogous product on heating to 140° C. Similar imine bases were prepared from *p*-anisidine, *p*-nitraniline and naphthionic acid; they are suitable for the preparation of azo dyestuffs on the fibre. The imine base from diaminodiphenylmethane has the constitution,

$$CH_2{<}^{NH}{>}C_6H_2{<}^{CH_2}{>}C_6H_2{<}^{CH_2.O.CH_2}{>}C_6H_2{<}^{NH,}_{CH_2},$$

and is slightly soluble in mineral acids. *p*-Toludine yields a mixture of the compounds,

$$(4)NH{<}^{(3)CH_2}{>}C_6H_2(CH_3).CH_2.O.CH_2.C_6H_2(CH_3){<}^{NH}_{CH_2}\text{ and}$$

$$NH{<}^{CH_2}{>}C_6H_2(CH_3).CH_2.C_6H_2(CH_3){<}^{NH.}_{CH_2}$$

On treatment with hydrochloric acid and sodium nitrite, these bases are converted into isonitroso compounds, which yield dyestuffs with alkaline β-naphthol. *o*-Toluidine yields the compound,

$$(1)\ (CH_3)C_6H_3{<}^{NH(2)}_{CH_2(3)}.$$

Since *o*-substituted bases yield compounds containing only three groups united to the benzene rings, whilst *p*-substituted bases yield compounds containing four such groups, it follows that groups in the ortho position hinder the introduction of the CH_2OH group into the benzene nucleus.—A. S.

Benzylene-imides. E. Orloff. J. russ. phys.-chem. Ges., 1906, **37**, 1272 -1277. Chem. Centr., 1906, **1**, 1416.

A MIXTURE of 1 mol. of tartaric acid and 2 mols. of formaldehyde in 35—40 per cent. solution, is heated in a closed flask and then, after cooling, 2 mols. of aniline are gradually added, cooling the mixture by water if necessary. The reaction product is dissolved in hot 70 per cent. acetic acid, the solution concentrated, the residue dissolved in water and alkali, alkali carbonate or ammonia added. A white precipitate is produced which gradually turns yellow. After drying at 100° C., the product, benzylene-imide, has the formula:

$$\left[C_6H_4{<}^{NH}_{CH_2}\right]_4.3H_2O.$$

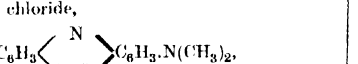
It is soluble in hot acetic acid, insoluble in alcohol and ether. With nitrous acid it yields an isonitroso compound, which forms dyestuffs with alkaline β-naphthol, and can thus be used for the preparation of dyestuffs on the fibre.

For technical purposes, it is not necessary to isolate the imine base, the acetic acid solution being used directly for the production of the isonitroso compound. Benzylene-imide can also be obtained by first preparing anhydro-formaldehyde-aniline from formalin and aniline, and heating this with a mixture of aqueous tartaric acid and glacial acetic acid. 55 grms. of the base are obtained from 35 grms. of 35 per cent. formalin and 37 grms. of aniline. The tartaric acid may be replaced by citric acid. Imide bases were also prepared in an analogous manner from *o*-anisidine and *o*- and *p*-toluidine. The base from *o*-anisidine can be used for the production of dyestuffs on the fibre.—A. S.

Thionine and Azoxine dyestuffs; Constitution of ——. A. Hantzsch. Ber., 1906, **39**, 1365—1366.

THE author admits that Kehrmann's recent publication (see Ber., 1906, 914; this J., 1906, 423) contains experimental evidence in support of his thionium and oxonium formulæ for dyestuffs of the Methylene and Meldola Blue type. The present short notice is intended to close the discussion.

—H. L.



Methylene Azure. F. Kehrmann. Ber., 1906, **39**, 1403—1408.

(A) 10 grms. of Methylene Blue chloride were dissolved by warming in 1 litre of water, the solution cooled, treated

with 10 c.c. of a 40 per cent. solution of caustic soda, and allowed to stand for 24 hours. After passing a current of air through for half an hour, a further 5 c.c. of caustic soda solution were added, and the whole allowed to stand for a further 12 hours, with occasional agitation. The solution was then made faintly acid with acetic acid, diluted to 1½ litres, heated to 40°—50° C., and after filtering, if necessary, repeatedly extracted with chloroform to remove Methylene Violet. The residual aqueous solution was made strongly alkaline with caustic soda, and the Methylene Azure base extracted with chloroform. From the chloroform solution, the acetate of the colour base was obtained by shaking out twice with 50 c.c. of water containing a few drops of glacial acetic acid. The filtered solution of the acetate was treated with the necessary quantity of concentrated hydrochloric acid, and after standing for 24 hours, Methylene Azure chloride was obtained in brownish glistening needles with a faint greenish lustre.

(B) About 1 grm. of Methylene Azure iodide obtained by Bernthsen's method (Annalen, 1885, **230**, 170) by the oxidation of Methylene Blue with silver oxide, was extracted several times with hot water, the solution cooled, made strongly alkaline with caustic soda, and extracted with chloroform. From the chloroform solution, Methylene Azure acetate was obtained as described above, and from this the chloride was separated by treatment with hydrochloric acid and sodium chloride. The product was similar to but not identical with that described under (A), being somewhat more soluble, and giving a more bluish-green solution in concentrated sulphuric acid.

By comparison with synthetically prepared products, the author identified compound (A) as unsymmetrical dimethylthionium chloride,

and compound (B) as trimethylthionium chloride,

Whether the Methylene Azure obtained consists chiefly of trimethylthionine or of dimethylthionine depends upon the method of preparation and purification. If, for example, a mixture of the chlorides of the two compounds mentioned be repeatedly crystallised, the final product consists of almost pure dimethylthionine chloride, the more soluble trimethyl compound remaining in the mother liquors.—A. S.

English Patents.

Dyestuffs; Manufacture of new raw materials and of new azo —— therefrom. G. Nuth, Neuilly sur Seine, H. Hold and H. Ruegg, Paris. Eng. Pat. 14,618, July 15, 1905. Under Int. Conv., July 16, 1904.

See Fr. Pat. 344,844 of 1904; this J., 1904, 1210.—T. F. B.

Indigo paste; Manufacture of - - . J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 1954, Jan. 25, 1906.

Indigo pastes for the fermentation vat, *e.g.*, those prepared according to Eng. Pat. 3108 of 1904 (this J., 1905, 24) have the disadvantage that, when used for dyeing, there is a certain delay while the indigo is being reduced. It is now found that if a reduced form of indigo, for instance indigo-white, be employed instead of indigo, stable pastes are obtained which yield at once a vat suitable for dyeing. For example: 1600 parts of a 50 per cent. indigo-white press-cake are mixed with 450 parts of bran, 200 parts of wheat flour, 200 parts of quicklime, and 1550 parts of water to form a homogeneous paste. It is stated that the proportion of quicklime should never be less than about 25 per cent. of the amount of fermentable substances present in the paste.—A. S.

Dyestuff; Manufacture of a red vat dyeing —— [Thio-Indigo Red]. O. Imray, London. From the Society of Chemical Industry, Basle, Switzerland. Eng. Pat. 4687, Feb. 26, 1906.

A red vat dyestuff having the constitution of indigo in which the imino groups have been replaced by sulphur, can be obtained from salicylthioacetic acid, $COOH.C_6H_4SCH_2.COOH$—(1) by heating it either alone or in presence of a condensing agent such as acetic anhydride, and then treating the product in alkaline solution with an oxidising agent (air, sodium hypochlorite, potassium permanganate); or (2) by heating it in presence of a suitable solvent capable of yielding oxygen, *e.g.*, a nitro derivative of an aromatic hydrocarbon.

Examples.—(1) Ten parts of salicylthioacetic acid are mixed with 50 parts of acetic anhydride and boiled under a reflux condenser for about five hours. The acetic anhydride is distilled off, the residue dissolved in dilute caustic soda lye, and the dyestuff precipitated by heating with an aqueous solution of 10 parts of potassium permanganate. To purify the dyestuff from co-precipitated manganese dioxide, it is dissolved by addition of 5 parts of sodium hydrosulphite (hyposulphite), the solution is filtered, and the dyestuff re-precipitated by a current of air. (2) Ten parts of salicylthioacetic acid are boiled for about five hours with 50 parts of nitrobenzene under a reflux condenser, the mixture is cooled, and the dyestuff which has separated in the form of lustrous, brownish-red crystals, is collected, washed free from adhering nitrobenzene by alcohol, and dried. (See also this J., 1906, 367; also Kalle und Co., Fr. Pats. 359,398, 359,399 and 359,400 of 1905; this J., 1906, 424, 426.)

Vat dyestuff; Production of a new ——. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 360,292, Dec. 9, 1905. Under Int. Conv., Jan. 30, 1905.

A NEW dyestuff which can be applied from a vat in the same way as indigo is obtained by heating with alkali the glycin formed by the action of chloracetic acid on dianthranilic acid.

Example.—31·6 kilos. of sodium dianthranilate are dissolved in water and 25 kilos. of sodium chloracetate added; the solution is heated under a reflux condenser until the yellowish-brown product which separates, no longer increases in quantity. This is filtered off, washed with water and dissolved in sodium carbonate solution to obtain a neutral solution of the sodium salt of the glycin. It is finally evaporated to dryness. Twenty kilos. of this salt are introduced into a mixture of 20 kilos. of caustic soda and 20 kilos. of caustic potash heated to 250° C. The mass is heated for a short time at 270°—280° C. The cold melt is dissolved in water and the dyestuff separated as green flocks by passing in air.

—A. B. S.

Dyestuffs; Process for making yellow to orange-yellow sulphide ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 360,780, March 10, 1905.

SEE Eng. Pat. 27,091 of 1904; this J., 1905, 1167.—T.F.B.

Dyestuffs of the anthracene series; Production of new ——. Badische Anilin und Soda Fabrik. Seventh Addition, dated Nov. 9, 1905, to Fr. Pat. 349,531 of Dec. 21, 1904. Under Int. Conv., Oct. 9, 1905.

BY treating the dyestuffs produced by the action of alkalis on the benzanthronequinolines and benzanthrones with halogens, new dyestuffs are obtained which differ slightly in shade from the original dyestuffs, and, as a rule, are more easily reduced in the dye-vat.

Example.—One kilo. of cyananthrene is suspended in 10 kilos. of nitrobenzene at 60°—70° C., and a current of dry chlorine is passed in until a sample, precipitated with alcohol, gives with an alkaline solution of hydrosulphite (hyposulphite) a vat of a greenish-blue colour. The dyestuff is then precipitated with alcohol, filtered, washed with alcohol and dried. —A. B. S.

Indigo white; Production of dry, stable alkali salts of ——. Badische Anilin und Soda Fabrik. Fr. Pat. 360,447, Dec. 9, 1905. Under Int. Conv., Oct. 7, 1905.

SEE Eng. Pat. 23,122 of 1905; this J., 1906, 65.—T. F. B.

GERMAN PATENTS.

Dyestuffs of the cyanine series; Process of preparing sensitising ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 167,770, May 26, 1903. Addition to Ger. Pat. 167,159, March 14, 1903.

INSTEAD of using toluquinoline or toluquinaldine for the preparation of cyanine dyestuffs as described in the principal patent (see Eng. Pat. 9598 of 1903; this J., 1904, 384), methoxy- or ethoxy-quinoline or -quindaldine is employed. *p*-Toluquinaldine-*p*-methoxyquinolinecyanine ethyl iodide and *p*-methoxyquinaldine-*p*-toluquinolinecyanine ethyl iodide are specially mentioned. These new dyestuffs are stated to produce photographic emulsions possessing high red-sensitiveness; the sensitive band is very even, with no break in the green; the plates obtained are said to be stable and free from tendency to fog.—T. F. B.

Chloroindigo; Process of preparing ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 167,830, March 5, 1904.

DRY indigo or one of its salts is suspended in an indifferent solvent (*e.g.*, carbon tetrachloride) and treated with chlorine in presence of some chlorine-carrier (*e.g.*, iodine), either at the ordinary pressure, or at increased pressure According to the extent of the chlorination, the product dyes redder and brighter shades. The dichlorinated product is said to give very similar dyeings to the product obtained synthetically from *m*-chloronitrobenzaldehyde.

—T. F. B.

Lakes [from azo dyestuffs]; Process of preparing red colour ——. Meister, Lucius und Brüning. Ger. Pat. 165,823, Aug. 20, 1904. XIIIA., page 486.

Dyestuffs; Process of preparing new blue mordant oxazine ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 166,079, Oct. 7, 1904.

GALLOCYANINES are condensed with one of the aminobenzoic acids in presence of a suitable solvent, at a high temperature; the resulting oxazine dyestuffs are soluble in water, and bluer in shade than the original gallocyanines. They are applicable directly to dyeing and printing, and produce fast lakes with chromium mordants on animal or vegetable fibres.—T. F. B.

α-β-Nitromethoxyanthraquinones; Process of preparing ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 167,699, Nov. 8, 1904.

THE two dinitroanthraquinones (*α-β-* and *α-α'-*) obtained by nitrating anthraquinone, and separated by fractional crystallisation, behave differently when heated with alkali methylate; the *α-α'*-derivative is converted into the dimethoxyanthraquinone, whilst, if equal mols. of the methylate and dinitroanthraquinone are used, the latter is converted into *α-β*-nitromethoxyanthraquinone. It differs from the *α-β*-dinitro-compound in being easily soluble in concentrated sulphuric acid; it can also be readily crystallised.—T. F. B.

Dyestuffs; Process of preparing mordant-dyeing o-hydroxymonoazo ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 167,333, Feb. 5, 1905.

THE diazo derivative of *o*-aminophenol is combined with chromotrope acid in strong caustic alkali solution. The dyestuff dyes wool from acid baths in Fuchsin red shades, and gives fast blue shades on chrome-mordanted fibr (s.

—T F. B.

Diaminodinaphthazines; Process of preparing ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 166,363, Feb. 8, 1905.

DINAPHTHAZINE is nitrated with 2 mols. of nitric acid in concentrated sulphuric acid solution, and the resulting dinitro-compound reduced in the usual manner to diaminodinaphthazine; this differs from the known aminoazines in that it gives no hydroxy-derivatives by heating under pressure with hydrochloric acid. By diazotisation and combining with the usual components, azo dyestuffs are obtained giving dyeings on cotton which are fast to washing.—T. F. B.

Dyestuffs susceptible to chroming; Process of preparing azo ——. L. Cassella und Co. Ger. Pat. 167,640, Oct. 22, 1903.

o-AMINO-*o*-NITRO-*p*-ACETAMINOPHENOL is diazotised and combined with aminonaphtholsulphonic acids or dihydroxynaphthalenesulphonic acids. The 2.3.6-, 2.8.6-, and 1.8.4-aminonaphtholmonosulphonic acids, 1.8.2.4- and 1.8.3.6-aminonaphtholdisulphonic acids, 1.8.4-dihydroxynaphthalenemonosulphonic acid and 1.8.3.6-dihydroxynaphthalenedisulphonic acid are specially mentioned. The dyestuffs dye wool in blue shades, converted to green by chroming; the dyeings are fast to washing and light.

—T. F. B.

Phenylglycin; Process of preparing ——. A. Wohl and O. Blank. Ger. Pat. 167,698, Nov. 25, 1903.

A SALT of chloracetic acid is treated with excess of aniline in presence of a quantity of an alkaline-earth which is sparingly soluble in water (*e.g.*, calcium or magnesium carbonate).—T. F. B.

Dyestuff; Process for preparing a disazo ——. Kalle und Co., A.-G. Ger. Pat. 166,980, Aug. 11, 1904.

THE intermediate product obtained from tetrazotised

nitrobenzidine and salicylic acid is combined with 1.2-naphtholsulphonic acid. The dyestuff produces red-brown shades on wool from sulphuric acid solutions, the shades being converted into fast orange-brown dyeings on subsequent chroming. Other naphthol-sulphonic acids only form red dyestuffs by this method. T. F. B.

p-Mono- and p-dichloroanthrarufin [Anthracene dyestuffs]; Process of preparing . R. Wedekind und Co. Ger. Pat. 167,743, Aug. 19, 1904.

ANTHRARUFIN is suspended in boiling, dilute sulphuric acid (b. pt. 140° C.) and chlorine is passed into the mixture. According to the amount of chlorine added, the *p*-mono- or *p*-dichloroanthrarufin is obtained. Both are converted into pure blue dyestuffs by condensation with aromatic amines.—T. F. B.

Dyestuffs; Process of preparing brown sulphide —. K. Oehler. Ger. Pat. 167,429, Oct. 21, 1904. See U.S. Pat. 801,598 of 1905; this J., 1905, 1167.

BESIDES *m*-phenylenediamine, other diammo- and dinitro-compounds of the benzene series may be heated with methylenediresorcinol and sodium sulphide to form brown sulphide dyestuffs. T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 426.)

Animal textile fibres; Phenomena accompanying the dyeing of —. P. Gelmo and W. Suida. Monatsh Chem., 1906, **27**, 225—235.

IN a previous communication (this J., 1905, 920) the authors, in referring to the action of cold solutions of ammonia and hydrochloric and sulphuric acids on wool, gave absorption-values, which had been erroneously stated, and should have been expressed in the following proportions:—(1) NH_3:20HCl:24H_2SO_4/2 and (2) NH_3: 20HCl:21H_2SO_4/2, so that the basic character of wool is shown to be even greater than was previously supposed. In order to determine the changes which accompany the hydrolysis of wool in the process of dyeing, a series of experiments was made, in which the wool was boiled for one hour, 21 and 60 hours respectively, with distilled water, dilute hydrochloric acid, dilute ammonia and dilute sodium carbonate solution. Each specimen was then washed with cold distilled water until the washings were free from the reagents employed, and, after drying, titrated with N/10 solutions of sulphuric acid, hydrochloric acid and ammonia, using methyl orange as indicator. The results given in the following table show that in the early stages of the treatment the acid character of wool is increased without, however, changing its basic nature:

	Proportion of		
	NH_3.	HCl	$\frac{1}{2}H_2SO_4$
Untreated wool	1	17·3	20·3
Wool treated with H_2O for 1 hour	1	8·1	9·8
" " " HCl " "	1	3·6	3·8
" " " NH_3 " "	1	8·4	9·1
" " " Na_2CO_3 "	1	9·4	9·9

By prolonging the treatment the increase in acid character is gradually lessened (except in the case in which the wool was treated with sodium carbonate), and from this result it is inferred that the hydrolytic disintegration does not proceed uniformly throughout the entire operation, but is more energetic in its action at the commencement of the treatment. The experiment in which water alone was used, shows that a considerable proportion of the wool-substance goes into solution, and that this decomposition is accompanied by an increase in the acid character of the wool. The action of dilute hydrochloric acid is similar to that of water, whilst the effect of ammonia is to dissolve a much larger amount of the wool-substance. Sodium carbonate also occasions a considerable diminution in the weight of the wool, and changes the proportion of acid and basic properties in the early part of the treatment. Specimens of untreated wool and of wool treated with water, ammonia and sodium carbonate were dyed with Crystal Violet and Crystal Ponceau in a neutral bath, washed with hot water and soaped at 70° C. The dyeings were the same in each case, the only difference being that with Crystal Violet the untreated wool was faster to soaping than the treated specimens. The colours obtained with Crystal Violet on wool treated with hydrochloric acid were weaker and more unstable to soaping than those produced with untreated wool. Although wool boiled with dilute acid is more intensely dyed by Crystal Ponceau in a neutral bath, its stability to soaping is greatly reduced. Further experiments on the treatment of wool with alcoholic sulphuric acid have shown that the fibre acquires considerable affinity for the acid, combining therewith so intimately that it cannot be removed by washing with cold water. It is, however, liberated by treatment with hot ammonium carbonate solution. This result points to the presence of a fairly stable salt in the wool. Wool, which has been treated with the above-named reagents, gives with diazonium compounds, stronger colours than when dyed therewith without previous treatment. A similar effect was produced with Millon's reagent.—D. B.

Hydrosulphites; Recent work on . A. G. Green. J. Soc. Dyers and Col., 1906, **22**, 9—11.

THE author discusses recent work on the hydrosulphites. In 1900, Bernthsen and Bazlen (this J., 1900, 244) obtained the salt, $Na_2S_2O_4.2H_2O$, in a tolerably pure form by saturating the solution of the crude compound with common salt. In 1902, the anhydrous salt, $Na_2S_2O_4$, was obtained by treating the hydrated salt with boiling strong alcohol (see Fr. Pat. 341,718 of 1904; this J., 1904, 900). It is a fine white friable powder, much more stable than the hydrated salt, and is sold under the name of "Hydrosulphite B.A.S.F." By acting on sodium hydrosulphite solution with formaline, Baumann, Thesmar and Frossard (this J., 1904, 658) obtained a product having the empirical formula, $Na_2S_2O_4.2CH_2O.4H_2O$, which they named sodium hydrosulphite-formaldehyde; it is sold under the names "Hydrosulphite N.F" and "Hyraldite A." Subsequently it was discovered that this product is not a single compound, but is a mixture in molecular proportions of sodium bisulphite-formaldehyde, $NaHSO_3.CH_2O$, and a new compound, $NaHSO_2.CH_2O$, named by Baumann, Thesmar and Frossard (this J., 1904, 1211) sodium bihydrosulphite-formaldehyde, but re-christened by Bernthsen (this J., 1905, 329) sodium sulphoxylate-formaldehyde. Sodium sulphoxylate-formaldehyde, in the pure state, forms large colourless crystals containing 2 mols. of water; it is sold under the name "Rongalite C" [also as "Hydrosulphite N.F extra" or "conc." or "extra conc.," and "Hyraldite C"], and has double the reducing power of "Hydrosulphite N.F" or "Hyraldite A." The discovery of this compound led to further controversy as to the constitution of sodium hydrosulphite (see Baumann, Thesmar and Frossard, this J., 1904, 1211; Prud'homme, this J., 1905, 89; Bernthsen, Bazlen, and Reinking, Dehnel and Labhard, this J., 1905, 329, 330). The general conclusions to be drawn appear to be that sodium hydrosulphite is an anhydride salt derived from equal molecules of sulphurous and sulphoxylic acids:

$$O\!<\!\begin{matrix}S.ONa\\SO.ONa\end{matrix}$$

This salt is stable in aqueous solution, but when treated with formaldehyde, it reacts according to the equation:—

$$O\!<\!\begin{matrix}S.ONa+2CH_2O\\SO.ONa+H_2O\end{matrix} =$$

HO.CH_2O.S.ONa (sodium sulphoxylate-formaldehyde)
and
HO.CH_2O.SO.ONa (sodium bisulphite-formaldehyde)

—A. S.

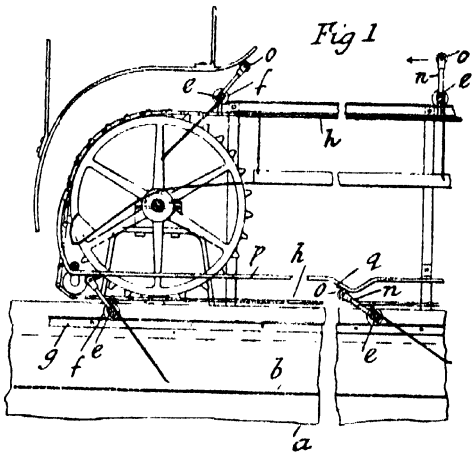
α-Naphthylamine Claret; Discharging ——. L. Baumann and G. Thesmar. Z. Farben-Ind., 1906, **6**, 121—125.

THE discharge printing-mixture, containing as active ingredients sodium sulphoxylate-formaldehyde, ferric citrate, sodium nitrite, and glycerin, particulars of which have recently been published (this J., 1906, 371), has been successfully employed for some months at the print works of E. Zündel, in Moscow. Although its cost is a little higher than that of the thickened solution of sodium sulphoxylate-formaldehyde (composed of 40 per cent. of "Hyraldite A"), which, as H. Werner points out (Z. Farben-Ind., 1906, 94), discharges dyeings of Naphthylamine Claret when printed and steamed at a relatively high temperature in Simon and Weckerlin's apparatus (this J., 1905, 1226), its use offers important advantages in practice. Thus, in the first place, deeper shades of claret are discharged by it under ordinary conditions of steaming than can be discharged by means of the simple "Hyraldite" mixture with the aid of superheated steam. At the lower temperature of steaming, again, there is little or none of the sublimation of azo dyestuff from the interior to the surface of the fibre which occurs at higher temperatures. The ground colour steamed in the ordinary manner is thus faster to rubbing than that which has been exposed in this operation to a higher temperature. Further, the "whites" obtained at the lower temperature with the mixture of ferric citrate, &c., are much purer than those produced by the unassisted "Hyraldite" at a temperature of 120°—125° C. This is due to the fact that at the higher temperatures, sodium sulphoxylate-formaldehyde (or "hydrosulphite formaldehyde") is decomposed into thioaldehyde, sodium sulphide, sulphur and other substances, some of which remain on the fibre after washing and soaping and discolour the "whites." The change which the reducing agent undergoes at the ordinary temperature of steaming is pure one of oxidation of sulphoxylate formaldehyde into sodium bisulphite-formaldehyde, without the formation of secondary products. Finally, under the influence of superheated steam, some of the basic dyestuffs employed in the production of coloured discharges are destroyed by over-reduction.

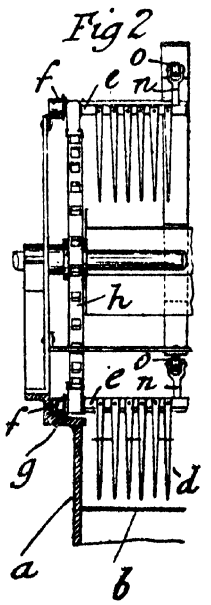
The apparatus used by the authors in effecting discharges on Claret-dyed grounds, is an ordinary Mather Platt ager. It has no special internal heating arrangements. Steam is admitted to it under a pressure of 2 kilos. The temperature within the apparatus is 102°—103° C., and the duration of the operation is three to three and a half minutes. Small chambers are recommended in preference to those of larger size.

The treatment of the tissues with dilute acid, which follows the steaming and washing operations, has for its object the removal from the tissues not only of traces of iron left in them, but also that of small quantities of reduction-compounds, resulting from the decomposition of the azo dyestuff, namely, α-naphthylamine and α-amino-β-naphthol, which are not as a rule completely removed by washing and soaping alone. If imperfectly removed, they become oxidised and soil the "whites" during the storage of the tissues.

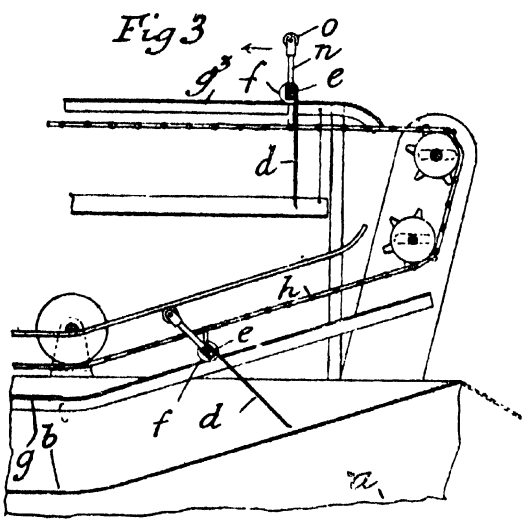
Temperatures of 120°—125° C. would thus appear to be not only not essential, but positively harmful, in steaming tissues dyed in α-Naphthylamine Claret for the production of discharges by means of printing-mixtures containing sodium sulphoxylate-formaldehyde. The authors consider, however, that Simon and Weckerlin's apparatus may be serviceable in giving temperatures of 110°—115° C. for the steaming of this style, but think that the latter temperature cannot safely be exceeded.—E. B.



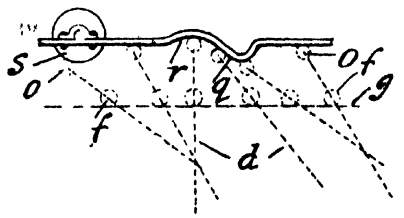
ENGLISH PATENTS.



Threads; Manufacture of artificial ——. R. Linkmeyer, Herford, Germany. Eng. Pat. 4746, March 7, 1905. Under Int. Conv., April 6, 1904.



A LARGE proportion of the ammonia employed can be recovered from the solutions of cellulose-cuprammonium without causing precipitation of the cellulose; this is best effected by agitating the solution *in vacuo*, at a temperature not below 45° F., the ammonia being continually withdrawn from the apparatus. A thick liquid is thus obtained, which is stated to be easily filtered, and to solidify readily in contact with suitable precipitants.—T. F. B.



Wool scouring machines. T. A. Jones, Melbourne, Australia. Eng. Pat. 17,026, Aug. 22, 1905.

RAKES, composed of bars, *e* (see Figs.), and teeth, *d*, (Figs. 2, 3 and 4), having at their ends supporting rollers, *f*, running on rails, *g*, are conveyed by means of endless chains, *h*, through a scouring tank, *a*, provided with a false bottom, *b*. From the middle of each rake projects a shank, *n*, surmounted by an anti-friction device, such as a roller, *o*, coming into contact with a rail, *p*, so disposed as to keep the rake inclined forwards as it is carried through the tank. At intervals, devices, such as projections, *q*, from, or recesses, *r*, in the rails, *g*, or discs, *s*, mounted on the latter, are arranged in the path of the rollers, *o*, to cause the rakes to be tilted up or down. After arriving at the exit-end of the apparatus, the rakes return above the tank to the

entrance-end, the rollers, *f*, running upon an upper rail, g^3, and the rakes hanging freely downwards. The tank when in use is filled with a solution of a suitable cleansing agent, *e.g.*, soap, the scouring action of which upon the loose wool is assisted by the agitation produced by the tilting motion given to the rakes by which the wool is propelled through the tank.—E. B.

Dyeing, scouring and other treatment of textile materials by liquids; Impts. in —— and in apparatus therefor. O., J. and C. Obermaier, Lambrecht, Germany. Eng. Pat. 17,568, Aug. 30, 1905. Under Int. Conv., Aug. 30, 1904.

See Fr. Pat. 345,945 of 1904; this J., 1905, 87.—T. F. B.

Discharging dyed materials and pastes therefor. J. Y. Johnson. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 15,524, July 28, 1905.

Neutral or slightly alkaline pastes for discharging in pattern dyeings of Naphthylamine Bordeaux, Paranitraniline Red, Chloranisidine Orange, Orthonitrotoluidine Yellow, Dianisidine Black, Chrysoidine Bistre and analogous compounds on textile materials, are prepared from sodium hydrosulphite (hyposulphite-)formaldehyde or sodium sulphoxylate-formaldehyde, along with a metal, metallic oxide or metallic salt, which either is itself a reducing agent or is capable of acting as a carrier of "the reducing power" (the salts of iron, *e.g.*, "iron chloride" and "iron sulphate" being preferred), a nitrite, Turkey-red oil, an alkali citrate and a neutral thickening, *e.g.*, starch and gum tragacanth paste. The discharges are effected by steaming for a few minutes the tissues printed with these pastes, then washing, souring, and soaping. Colour discharges are obtained by adding suitable dyestuffs, in some instances along with mordants, to the white discharge mixtures. As the latter are neutral or only slightly alkaline, they may be employed in discharging dyeings on textile materials composed of animal fibres. (See this J., 1906, 371, also page 473.)—E. B.

Fibre; Production of brown shades on the —— with or without white or coloured discharge effects. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 17,241, Aug. 25, 1905.

See Fr. Pat. 357,472 of 1905; this J., 1906, 120.—T. F. B.

Ketone sulphoxylates; Manufacture of ——. Farbwerke vorm. Meister, Lucius und Brüning, Hoechst on Maine, Germany. Eng. Pat. 4073, Feb. 19, 1906. Under Int. Conv., Sept. 30, 1905.

Ketone-sulphoxylates are produced by subjecting to the action of reducing agents compounds or mixtures of acetone or methylethylketone with sulphurous acid, bisulphites or hydrosulphites (hyposulphites). For example, 200 parts of zinc dust, stirred into a paste with a little water, are introduced into a solution of 130 parts of acetone in 520 parts of sodium bisulphite at 20° B. and 500 parts of water. The mixture is heated at 50°–60° C. as long as an increase in its reducing power is observed to take place. It is then cooled, filtered and evaporated in a vacuum. The reaction is accelerated by the presence of a zinc salt, *e.g.*, zinc chloride. The ketone-sulphoxylates obtained by this method differ, it is stated, from formaldehyde-sulphoxylates in being less stable than the latter, being capable, for instance, of reducing indigo-sulphonic acid in the cold. They also act more powerfully than formaldehyde compounds in the discharge of dyeings of Naphthylamine Claret and similar dyestuffs.—E. B.

Textile fabrics; Manufacture of pastes for discharging dyed — . J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 26,381, Dec. 18, 1905.

Discharge printing-mixtures, stated to be of excellent stability, are prepared from hydrosulphites (hyposulphites) free from water of crystallisation, a sugar or a concentrated solution of a sugar, *e.g.*, the uncrystallisable or difficultly crystallisable syrups obtained in the manufacture of sugar, and thickening agents; a mixture is made, for example, of 2 parts of British gum, 2 parts of water, 3 parts of "sodium hydrosulphite B.A.S.F." in powder, and 3 parts of sugar syrup. The tissues printed with this are steamed for a few minutes and then washed as usual.—E. B.

United States Patent.

Bleaching composition. A. E. Nienstadt, Newark, N.J., Assignor to G. W. Kuehler, New Rochelle, N.Y. U.S. Pat. 817,267, April 10, 1906.

Claim is made for a powder consisting of 1 part of sodium peroxide mixed with 4 parts of anhydrous sodium carbonate.—A. B. S.

French Patents.

Silk; Manufacture of artificial ——. H. E. A. Vittenet. First Addition, dated Feb. 3, 1905, to Fr. Pat. 350,383, Dec. 8, 1904 (this J., 1905, 921).

The opacity of the threads formed from gun-cotton and acetone is said to be due to the presence of moisture which gives rise to a mixed hydrate of nitrocellulose and acetone. If cellulose be considered to have a ketonic group (CO), the equation can be written thus:

$$(CH_3)_2CO + (OC) : C_6H_{10-n}(NO_2)_nO_4 + H_2O = (CH_3)_2C(OH).O.C(OH) : C_6H_{10-n}(NO_2)_nO_4.$$

To obtain a clear thread this hydrate must be dissociated, and sulphur dioxide gas is employed for the purpose.—A. B. S.

Scouring machine; Inclined ——. G. Malard. Fr. Pat. 360,183, Oct. 7, 1905. Under Int. Conv., April 13, 1905.

The invention relates to a scouring machine in which the

usual horizontal trough is replaced by one at an angle of about 45 degrees. The wool is fed into a vertical portion attached to the upper end of this trough and slides by its own weight down the inclined bed, passing finally between a pair of squeezing rollers at the lower end. The trough is furnished with a perforated false bottom, which is divided into several divisions so that the scouring liquids from different portions of the trough are collected separately after passing through the wool. These various portions of liquid are run into tanks and forced by pumps through tubes ending in spray pipes which are placed along the upper surface of the tank. There is an automatic arrangement for using the various portions of liquid again in a continuous manner on the accumulator system, the portions saturated with grease, &c., being run off.
—A. B. S.

Silk; Boiling off, bleaching and dyeing of ——. Soc. Schmid Frères. First Addition, dated Jan. 21, 1905, to Fr. Pat. 345,173 of July 27, 1904.

For piece goods the machine consists of a closed tank, the upper portion of which is fitted with vertical rollers on which the pieces pass to and fro. The lower portion contains the soap bath, and is fitted with a steam coil for heating the solution, and also with a perforated coil for injecting air, which causes the soap to froth so that the foam fills the upper portion of the tank in which the pieces are moving. From this tank the pieces pass into a smaller similar one and then into another tank which contains a cone with sides inclined at about 20 degrees to the horizontal. The pieces pass over this cone and an inclined roller, and are so changed from a vertical to a horizontal position in which they pass through a number of washing tanks. For yarn, an endless chain which carries the yarn sticks is fitted in the soaping tank and has an arrangement for rotating the hanks during their passage.—A. B. S.

Silk; Process and apparatus for degumming, bleaching and dyeing ——. Soc. Schmid Frères. Second Addition, dated Feb. 3, 1905, to Fr. Pat. 345,173 of July 27, 1904 (this J., 1905, 24).

The process is essentially to carry out in one operation that described in the principal patent (*loc. cit.*). The hanks are passed over two or more horizontal rows of reels, being placed on the upper set of rollers, and removed from the lowest set. An arrangement is provided so that when the bottom set is emptied, the next higher one moves down and the empty set rises to the top and is ready for recharging.—A. B. S.

Yarns in the form of cops or on bobbins; Dyeing ——. H. L'Huillier. First Addition, dated Nov. 22, 1905, to Fr. Pat. 350,981, Jan. 24, 1905 (this J., 1905, 888).

To prevent the movement of the bobbins during the circulation of the dye liquor, a plate is placed over them with holes into which pass the closed ends of the bobbin tubes. Close to each hole is placed a flexible plate which presses down on the particular bobbin and keeps it in place. The bobbins can also be kept in place by means of a small conical cap which fits over the end of the bobbin tube and is kept pressed against the bobbin by means of a screw. Instead of a screw the conical caps can be held in place by a plate passing over all the bobbins.—A. B. S.

Hydrosulphites; Process of making ——. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 360,620, Dec. 4, 1905. Under Int. Conv., Dec. 28, 1904.

See Eng. Pat. 26,173 of 1905; this J., 1906, 177.—T. F. B.

Aldehyde-hydrosulphites [-hyposulphites]; Preparation of ——. Chem. Fabr. von Heyden, Akt.-ges. Fr. Pat. 360,306, Dec. 11, 1905.

To obtain aldehyde-hydrosulphites free from aldehyde-bisulphites, sulphurous acid is run into a mixture of the aldehyde and zinc or iron powder in a quantity just sufficient to convert the zinc or iron into the hydrosulphite compound.

Example.—Into a well-agitated mixture of 65 kilos. of zinc dust and 80 kilos. of a 40 per cent. solution of formaldehyde, enough sulphurous acid is added to convert the zinc into the hydrosulphite compound (this requires about 53 kilos. of sulphur dioxide). The reaction is as under:

$$CH_2O + Zn + SO_2 + H_2O = OH.CH_2.OSOZn(OH).$$

The difficultly soluble zinc salt is ready for use, or it may be filtered, washed and dried *in vacuo*. By double decomposition with sodium carbonate, the sodium salt of formaldehyde-hydrosulphite ($HO.CH_2.OSONa$) can be obtained. This is easily soluble in water, and the solution can be separated from the zinc carbonate by filtration. This solution can be evaporated *in vacuo* either until it crystallises or to a dry powder. The products have more than twice the indigo-reducing power of the usual double compound of formaldehyde-bisulphite.—A. B. S.

German Patent.

Fibrous substances (textiles, leather, paper, &c.); Process for waterproofing ——. Chem. Fabr. Flörsheim, Dr. H. Noerdlinger. Ger. Pat. 166,350, May 12, 1904.

The material to be waterproofed is impregnated with an aqueous emulsion of ammonium salts of insoluble fatty or resin acids with fats, waxes, solid hydrocarbons, paraffin wax, ceresin, &c., and oils, and is afterwards dried, preferably by the aid of heat, in order to decompose the ammonium salts, and finally calendered or ironed.
—A. S.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(*Continued from page* 426.)

English Patent.

Printing processes [for wood, &c.]; Impts. in ——. W. E. Evans, London. From W. Goodwin, Owen Sound, Ontario, Canada. Eng. Pat. 6921, April 1, 1905.

With the object of printing upon surfaces of wood, textile fabrics, metal ware, &c., coloured patterns, in imitation of the graining of oak, mahogany and other woods, flat blocks or printing cylinders composed of, or having surfaces, *e.g.*, thin sheets or veneers, composed of these woods, are levelled and smoothed and then brushed with a stiff brush, such as a steel wire brush, to remove the softer parts of the wood and leave in the surfaces thus prepared, pits or recesses for the reception of the printing mixtures of ivory black, Vandyke brown, "japan," boiled linseed oil, &c., to be applied. Before use the blocks and cylinders are coated with oil to harden them. The printing is accomplished in the usual manner.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 427.)

Ammonia; Oxidation of —— to oxygen compounds of nitrogen. O. Schmidt and R. Böcker. Ber., 1906, **39**, 1366—1370.

Three series of experiments were made:—(1) Air or oxygen was passed through a N/10 solution of ammonia heated to 70°—90° C., and then through a combustion tube filled with platinised asbestos and heated in a furnace just to redness. The reaction products were absorbed in two vessels containing caustic soda solution (1:4). Four litres of air or oxygen were passed through in each experiment (one to two hours). (2) The second absorption flask contained an acid solution of permanganate instead of caustic soda solution. (3) Instead of platinised asbestos a platinum spiral was employed, heated just to redness by means of an electric current of 3½ ampères and 85 volts. After each experiment the ammonia taken up was determined by titration of the residual solution, the amount of ammonia oxidised by reducing a portion of the absorbing solution and titrating the ammonia

produced, and the nitrite by titrating another portion of the absorbing liquid with permanganate. The results are shown in the following table:—

SERIES I.

(*a*) *With oxygen.*

N/10 Ammonia used.	N/10 Ammonia after reduction	Ammonia oxidised	N/10 Permanganate used.	Nitrous acid, calculated from permanganate used.
26·89	13·50	64·62	23·72	87·82
41·45	31·90	75·77	39·72	62·26
33·20	25·74	77·53	47·22	91·72
41·69	26·34	63·17	38·22	72·55

(*b*) *With air.*

N/10 Ammonia used	N/10 Ammonia after reduction	Ammonia oxidised	N/10 Permanganate used.	Nitrous acid, calculated from permanganate used.
53·40	39·83	74·60	59·42	74·59
51·16	40·73	79·77	63·52	76·20
11·03	7·38	66·91	11·78	79·31
74·74	57·11	76·42	93·32	81·70

SERIES II.

N/10 Ammonia used.	N/10 Ammonia after reduction	Ammonia oxidised.	N/10 Permanganate used	Nitrous acid, calculated from permanganate used
13·07	10·13	70·62	8·79	43·39
22·63	18·45	81·53	34·04	94·69

49·04	32·63	66·54	60·22	92·28
16·41	12·55	70·08	35·84	143·18*

* In these experiments the oxidation products contained nitric oxide.

SERIES III.

N/10 Ammonia used	N/10 Ammonia after reduction	Ammonia oxidised	N/10 Permanganate used.	Nitrous acid, calculated from permanganate used
52·52	42·86	81·61	60·12	70·40
77·13	61·08	79·29	92·22	75·49

On raising the temperature (110 volts and 3¼ amperes), the yield of oxidation products was reduced from 81·61 and 79·29 to 65·18 per cent.

About 80—90 per cent. of the total oxidation products consist of nitrogen trioxide. The author concludes that, under the present conditions, the profitable production of nitric acid from ammonia according to Ostwald's process (Eng. Pat. 698 of 1902; this J., 1902, 548; also Addition to Fr. Pat. 317,544 of 1902; this J., 1903, 93) is not possible. For the manufacture of nitrous acid from ammonia, according to Bayer und Co.'s process (Fr. Pat. 335,229 of 1903; this J., 1904, 186), however, the conditions are different, and there appears to be no reason why, if a cheap supply of ammonia (*e.g.*, in the form of gas-liquor) be available, the technical manufacture of nitrites on these lines should not be successful.

—A. S.

Copper nitride; Preparation and properties of ——. A. Guntz and H. Bassett, jun. Bull. Soc. Chim. 1906, **35**, 201—207.

A COMPOUND containing about 93 per cent of copper nitride, Cu_3N, is obtained by heating amorphous yellow cuprous oxide for two hours in a current of dry ammonia gas at a temperature of 240°—265° C. The product has a dark green colour and always contains some metallic copper. When treated with concentrated sulphuric or hydrochloric acid the whole of the nitrogen of the compound is converted into ammonia. It is rapidly oxidised by concentrated nitric acid, about one-half the nitrogen being transformed into ammonia. Copper nitride completely decomposes at a temperature of 600° C., or a little higher. Alkalis attack the nitride but slowly even at a boiling temperature, a little ammonia and cuprous oxide being formed.—W. P. S.

Potassium chromate and potassium bichromate; Action of sulphur on ——. K. Brückner. Monatsh. Chem., 1906, **27**, 199—204.

WHEN potassium chromate is heated with excess of sulphur, out of contact with air, the products are chromium sulphide (in combination with potassium sulphide), potassium sulphate and some chromic oxide. On very strong heating, with access of air, only potassium sulphate and chromic oxide are obtained. Chromic oxide, and not the sulphide, likewise results when potassium bichromate is substituted for potassium chromate. It is probable that potassium sulphide and thiosulphate are the first products, the chromic anhydride being converted partly into chromic oxide and partly into the sulphide. The thiosulphate is then decomposed by heat into polysulphide and sulphate. Oxidation effects the final change to oxide and sulphate only.

Chromic anhydride and sulphur burn on heating together to yield chiefly chromic oxide which is not affected by sulphur at any temperature. Chromium sulphate or chrome alum, when heated with sulphur, are reduced to chromium sulphide (this J., 1906, 264).

—F. SODN.

Amorphous precipitations. I. Partial co-precipitation of bivalent bases in the precipitation of aluminium and chromium hydroxides. D. Strömholm. Arkiv för Kemi, 1905, **2**, Heft II., No. 9, 1—13. Chem. Centr., 1906, **1**, 1221—1222.

SOLUTION of aluminium or chromium chloride was mixed with one of calcium, magnesium, or barium chloride and with solution of ammonium chloride and ammonia of different concentrations, and the mixtures analysed after varying periods of time. The composition of the precipitate was calculated from that of the solution. The results obtained show that the violet chromium hydroxide carries down much more magnesium than the green modification does. When magnesium sulphate is used instead of magnesium chloride, the green chromium hydroxide carries down still less magnesium, but the amount carried down by aluminium hydroxide remains the same. In none of the cases examined was a chemical compound of ter- and bi-valent metal-hydroxide formed, the co-precipitation of the bivalent metal being due in all cases to adsorption.—A. S.

Amorphous precipitations. II. Basic salts of bivalent metal oxides. D. Strömholm. Arkiv för Kemi, 1906, **2**, Heft II., No. 16, 1—13. Chem. Centr., 1906, **1**, 1222.

SOLUTIONS of salts of heavy metals (lead, copper, zinc, nickel) were treated with mixtures of solutions of sodium hydroxide, carbonate, and bicarbonate, and after a condition of equilibrium had been attained, the solutions were analysed. In solutions containing large quantities of carbonate, some of the copper, nickel, and zinc always remained dissolved. Evidence was obtained of the existence of two basic carbonates of lead, $5PbO,3CO_2$, and $3PbO,2CO_2$, a basic zinc carbonate, $5ZnO,2CO_2$, and a basic nickel carbonate, $3NiO,CO_2$. With stronger acids than carbonic acid, the following amorphous basic salts were found to be formed: $4CuO,SO_3$, $4CuO,N_2O_5$, $4ZnO,SO_3$, $6NiO,SO_3$ and $6CoO,SO_3$.—A. S.

Phosphorus; Action of hydrogen peroxide on ——. T. Weyl. Ber., 1906, **39**, 1307—1314.

BY the action of boiling water, caustic soda solution, or hydrogen peroxide on yellow phosphorus, amorphous

phosphorus or Schenck's phosphorus (this J., 1902, 368; 1903, 494, 1225; 1904, 17) hydrogen phosphide and phosphorous and phosphoric acids are produced. The action of hydrogen peroxide solution is greater on amorphous phosphorus or Schenck's phosphorus than on yellow phosphorus. The last-named is not attacked perceptibly even by 30 per cent. hydrogen peroxide solution, until the mixture is heated to 60° C. The unattacked yellow phosphorus is converted, first, into a honey-like mass, and, later, into a horny substance, which scarcely fumes in the air, but when once ignited by a flame, burns like ordinary phosphorus. With amorphous phosphorus or Schenck's phosphorus the action is so vigorous as to be dangerous, if hydrogen peroxide solution of a strength greater than 8 per cent. be used, much heat being evolved. The reaction with amorphous phosphorus and Schenck's phosphorus is not due to the presence of yellow phosphorus, as even with carefully purified products the evolution of hydrogen phosphide is just as vigorous. The author considers that the primary product of the reaction is phosphorous acid, which is afterwards decomposed into hydrogen phosphide and phosphoric acid, a portion also being oxidised to phosphoric acid by the hydrogen peroxide.

$3H_2O_2+2P=2P(OH)_3$; $4P(OH)_3=PH_3+3PO(OH)_3$.

For the removal of yellow phosphorus from amorphous phosphorus or Schenck's phosphorus, the following process proved very satisfactory: About 10 grms. of the phosphorus to be purified are finely ground under water and boiled for about two hours with 200 c.c. of a 10 per cent. solution of sodium carbonate, under a reflux condenser. A. S.

Nitrous Acid; Oxidation of —— by hydrogen peroxide. Determination of nitrate in presence of nitrite. M. Busch. XXIII., page 499.

English Patents.

Sulphuric Acid; Purification of ——. V. C. Driffield, F. W. Wright, and The United Alkali Co., Ltd., all of Liverpool. Eng. Pat. 7916, April 13, 1905.

Arsenic is removed from sulphuric acid in the form of arsenious chloride, by treating the acid with hydrochloric acid or a chloride, and blowing air through it. If the arsenic is in the arsenic state, a reducing agent, such as sulphur dioxide, must also be added. A. G. L.

Sulphuric acid; Treatment of arsenical —— for the separation of arsenic, and the obtainment of arsenious chloride. J. Raschen, A. E. Wareing, J. H. Shores, and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 16,929, Aug. 21, 1905.

Arsenical sulphuric acid is subjected to the action of hydrochloric acid, preferably the dry gas, at a temperature of about 100° C. Sulphuric acid obtained from arsenical sulphur ores may be thus treated, being passed, for instance, as it leaves the Glover tower (cooled, if necessary, to the required temperature), into a suitably packed tower, where it is brought into contact with the hydrochloric acid gas. The arsenious chloride is separated from the sulphuric acid, in the receptacle at the bottom of the tower, as an oily liquid. E. S.

Arsenious acid; Treatment of arsenious chloride for the obtainment of ——. J. Raschen, A. E. Wareing, and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 16,930, Aug. 21, 1905.

Arsenious chloride, obtained, for instance, from arsenical sulphuric acid (see preceding abstract), is run into water containing an alkali, alkaline-earth, or carbonate thereof, a minimum proportion of water being used. The arsenious acid precipitates, and after separation from the liquid, may be sublimed, where calcium carbonate has been used as the reagent. When the reagent is sodium carbonate, so much should be dissolved in the water as may give a saturated solution of sodium chloride after precipitation of the arsenious acid.—E. S.

Arsenious acid; Treatment of arsenious chloride for the obtainment of ——. J. Raschen, J. T. Conroy, A. E. Wareing, and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 17,887, Sept. 4, 1905.

In the process for obtaining arsenious acid from arsenious chloride, described in Eng. Pat. 16,930 of 1905 (see preceding abstract) oxides or carbonates of the heavy metals, such as zinc oxide or carbonate, manganese-mud, or iron oxide, may be used in decomposing the arsenious chloride in presence of a minimum proportion of water, instead of the reagents there described. Eng. Pat. 16,931 of 1905 is also referred to.—E. S.

Hydrochloric acid; Manufacture of ——. I. L. Roberts, Lockport, U.S.A. Eng. Pat. 24,733, Nov. 29, 1905.

See U.S. Pat. 807,640 of 1905; this J., 1906, 218.—T.F.B.

Magnesium sulphate obtained in the known method of producing acetic acid by means of magnesium acetate; Processes of separating and working up ——. J. R. Garroway, Glasgow. Eng. Pat. 6798, March 31, 1905.

Pyroligneous acid, before or after distillation, according to whether a "brown" or "grey" salt is required, is neutralised with magnesium oxide or carbonate. To the concentrated solution in a still, sulphuric acid of about 120° T. is run in, and the distillation is proceeded with. Or, before distilling off the acetic acid, a portion of the magnesium sulphate may be crystallised out of the solution, and removed by filter-pressing or otherwise. The crude magnesium sulphate left in the still is heated in a suitable furnace, to char the tar, and the residue is worked up as Epsom salts.—E. S.

United States Patents.

Caustic alkali; [Electrolytic] Apparatus for and process of producing ——. H. S. Blackmore. U.S. Pats. 809,085 and 809,088, Jan. 2, 1906. XIA., page 483.

Caustic alkali; [Electrolytic] Process of making ——. H. S. Blackmore. U.S. Pat. 809,089, Jan. 2, 1906. XI.A., page 483.

Caustic alkalis and zinc sulphide; Process of manufacturing ——. C. Ranson, Brussels, Assignor to H. W. De Stuckle, Dieuze, Germany. U.S. Pat. 818,192, April 17, 1906.

See Fr. Pat. 353,480 of 1905; this J., 1905, 1013.—T. F. B.

Aluminate of soda; Manufacturing ——. S. S. Emery, Woodbury, N.J., Assignor to The Eastern Dynamite Co., Wilmington, Del. U.S. Pat. 818,754, April 24, 1906.

A mixture of bauxite, sodium sulphate, and carbonaceous matter is calcined in an air-blast, the air supplied being in excess, in order to produce an aluminate of soda free from impurities.—E. S.

French Patents.

Hydrochloric acid; Manufacture of ——. I. L. Roberts. Fr. Pat. 360,829, Dec. 2, 1905.

See U.S. Pat. 807,640 of 1905; this J., 1906, 218.—T.F.B.

Hydrochloric acid; Manufacture of —— by means of magnesium chloride. J. J. T. Schloesing. Fr. Pat. 360,356, Dec. 12, 1905.

Sea water or the mother liquors of salt marshes, as obtained by atmospheric exposure, are treated with a quantity of calcium chloride equivalent to the magnesium sulphate present, which is thus transformed into magnesium chloride with separation of calcium sulphate. The cleared liquor is further evaporated by exposure, and is then concentrated until it boils at a temperature of 130° C., and sufficient magnesium sulphate to transform the potassium chloride into sulphate is added. The cooled liquor is then filtered from the potassium sulphate and the sodium salts, &c., which separate, and is again heated with addition of magnesia, to transform the magnesium chloride solution into an oxychloride, which precipitates. This product is spread on superposed

ranges of acid-resisting bars in separate communicating compartments of a furnace, preferably heated by gas, in which the heated gases are successively led through the shelves and the different compartments. When the dehydration is complete, decomposition of the remaining magnesium chloride ceases; fresh portions of the oxychloride are then charged into the second compartment, and the direction of the gases is reversed, so that the dried charge in the first compartment is heated with access of steam, completing the decomposition. The flues of the furnace are arranged so as to avoid overheating any portion. The effluent acid gas is condensed in a coke tower in the usual way.—E. S.

Phosphates [*Bi-magnesium-hydrogen phosphate*]; *Manufacture of bi-basic —— by means of natural phosphates.* J. J. T. Schloesing. Fr. Pat. 360,357, Dec. 12, 1905.

Powdered native phosphates are treated with magnesium sulphate (or the mother liquors of salt marshes rich in that salt) and hydrochloric acid, in adjusted proportions. When solution of the ore is effected, as well as precipitation, partial or entire, of the calcium as sulphate, the solution is filtered and neutralised, not by milk of lime, as in the ordinary process, but by milk of magnesia, which gives a precipitate of bibasic magnesium phosphate, whilst the solution contains magnesium chloride, practically free from calcium. When it is desired that the precipitated phosphate shall contain calcium as well as magnesium, this is effected by reducing the proportion of magnesium sulphate added to the hydrochloric acid solution in the first stage of the process. The solution of magnesium chloride finally obtained, is concentrated by spontaneous evaporation on large plane surfaces, such as those of saline marshes, until the sodium chloride is deposited. The solution of magnesium chloride, containing also potassium chloride, may then be further treated, as described in the preceding abstract, to obtain hydrochloric acid and magnesia, available in treating fresh portions of native phosphates.—E. S.

Sulphuric acid; Process and apparatus for the manufacture and purification of ——. R. Cellarius. Fr. Pat. 360,634, Dec. 12, 1905.

The gases issuing from the lead chamber are drawn into the lower and central part of a closed lead tower, the sides of which are packed with a thick mass of coke, the central space being occupied by a hollow revolving shaft carrying curved arms, within which shaft is a perforated pipe conveying steam. A condensing agent is supplied to the coke, whilst the admitted gases, air, and steam are violently agitated, and dashed against the coke periphery. Such a tower may be interposed between the pyrites burner and the lead chamber (to purify the gases admitted), and also at the exit of each chamber; or it may replace the ordinary Gay-Lussac tower, in which case concentrated sulphuric acid is rained down from above, so as to moisten the coke against which the incoming gases are dashed by the centrifugal motion imparted by the revolving wings. Another form of tower, constructed of stone, has two inner walls or cylinders surrounding the central space in which wings are rotated, as in the former case. The inner walls are perforated, and the annular space between them is formed into a series of superposed compartments by a number of horizontal shelves, also perforated. The condensing agent is showered from above, and trickles through the compartments. The vertical iron rod carrying the ventilating wings is enclosed in a stoneware tube. The escape of gases from each intermediate tower, is from its side near the top to the next chamber. The same apparatus may be used for purifying and condensing hydrochloric acid gas, occurring in the manufacture of sodium sulphate; or generally in the like treatment of other gases, such as sulphur dioxide.—E. S.

Sodium dioxide and other compounds intended for the preparation of oxygen; Preservation of mixtures of —— against alteration due to atmospheric moisture. Cie. Gén. de Phonographes, Cinématographes et App. de Précision. Fr. Pat. 359,912, Nov. 29, 1905.

The compounds mentioned are coated with paraffin-wax.—E. S.

Alumina; Process for extracting —— from bauxite. G. Muth. Fr. Pat. 360,086, Dec. 5, 1905.

Bauxite is boiled with a soda lye of 27 per cent. strength in such proportion that for each molecule of alumina (Al_2O_3) in the bauxite, 1·7 molecule of soda [Na_2O] are used in the lye added. The solution obtained, after decantation, is agitated, to throw down the greater part of the aluminium hydroxide, and from the filtrate, the remainder is precipitated by milk of lime, and recovered by known means, the lye being thus obtained for re-use. —E. S.

Air; Process for the liquefaction of ——, and for obtaining oxygen. R. Mewes. Fr. Pat. 360,427, Nov. 27, 1905. Under Int. Conv., Nov. 27, 1904.

Compressed and cooled air is conducted under any desired pressure into a tube, curved upon itself at its further end, and having holes opening into a pipe enclosing the tube, except as to its curved end, which latter delivers a current or blast of the cold and compressed air in a direction contrary to that in which it arrived, into an enclosing cylinder in which a vacuum is maintained by a pump. This air flows, with more or less rapidity, over the surface of the liquid air, already formed in the cylinder, to which it thus adds continuously, whilst the unliquefied portion passes through the pump back to the atmosphere. Provision is made for tapping off the liquid air from the cylinder from time to time. The apparatus is arranged for the separation of oxygen by already known means. (See also Fr. Pat. 358,236 of 1905; this J., 1906, 180.)—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 428.)

English Patents.

Glass substitutes. J. Carl, London. Eng. Pat. 6816, March 31, 1905.

The glass substitutes described consist of fabric or gauze filled with gelatinous substances and subsequently treated with potassium bichromate. The fabric or wire gauze is steeped in an aqueous solution of chloride of lime, or ammonium chloride and ammonium sulphide, and dried. The gauze is then immersed in a heated solution of sodium silicate, alumina, and gelatin, partly cooled, and then immersed in a solution of albumin and water. The gauze thus prepared is said, by the subsequent treatment, to be rendered fire- and water-proof, and suitable for use as a glass substitute. The dried, prepared gauze is steeped in formalin, and then in a solution of potassium bichromate, and after five minutes' immersion, is dried in a dark room and then exposed to daylight. The yellow stains of the bichromate are removed by washing with a solution of alum and with water.—W. C. H.

Ceramic ware; [Electro-plated ——]. S. Heller and C. Baumgartl, of Teplitz, Austria, and Porzellanfabrik Ph. Rosenthal and Co., A. G. Filiale Kronach, Kronach, Germany. Eng. Pat. 10,833, May 24, 1905.

One part of enamel gold tombac ("an alloy consisting of copper, zinc and a small amount of gold") is mixed with 2 parts of enamel and 1 part of calcined borax, ground in oil of lavender, applied to the object and burnt at 800° C. After cooling, the coating is ground so as to render the metallic surface visible, after which the object is placed in an electro-plating bath in which the original metallic coating is reinforced by a further deposit. The object is then ground and polished.—A. G. L.

Enamelling iron or steel goods; Process for ——. R. F. Wagner, Halle-on-the-Saale, and H. L. Hermsdorf, Chemnitz, Germany. Eng. Pat. 17,292, Aug. 26, 1905.

See Fr. Pat. 356,726 of 1905; this J., 1906, 21.—T. F. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page 429.*)

ENGLISH PATENTS.

Cementitious material; Process for the preliminary treatment of blast-furnace slags for the production of ——. B. Bruhn, Hamburg, Germany. Eng. Pat. 8285, April 18, 1905. Under Int Conv., April 19, 1904.

SEE Fr. Pat. 354,790 of 1905; this J., 1905, 1110.—T. F. B

Slag; Treatment of ——, *and apparatus therefor.* T. W. Ridley, Middlesbrough. Eng. Pat. 9249, May 2, 1905

THE object of the invention is to produce annealed broken lumps of slag for macadam pavement. The slag is cast in moulds of a pyramidal form, attached to an endless chain, similar to a conveyor. When the moulds are inverted, the lump of cast slag drops out on to a conveyor, which delivers the cast blocks to a crane. The crane is arranged in the centre of a ring of annealing kilns, and feeds the cast blocks into the kilns through openings in the tops. The kilns are similar to those usually employed for annealing slag bricks, except for the opening in the top and for the fact that the floor is sloped downwards towards a delivery door. After the process of annealing, the blocks are withdrawn from the kilns, broken, and, whilst still hot, are mixed, if required, with tar.—W. C. H.

Wood; Preservation of ——. A. A. V. Poulsen, Lemvig, Denmark. Eng. Pat. 1325, Jan. 17, 1906.

THIS process for the "preservation" of wood consists in "loosely applying to its surface, or driving into it plates, pieces or nails (perforated or otherwise) of a metal, which, under the action of atmospheric or other moisture, will be transformed into a soluble metallic salt, which will soak into the wood," and preserve it against decay, dry rot, insects, &c. The process is applicable to wood structures *in situ*, and to those subject to alternate moist and dry conditions. W. C. H.

UNITED STATES PATENT.

Roads or other places; Compound which forms an emulsion with water to be applied to the surfaces of ——. E. Hardcastle, Stockport. U.S. Pat. 819,012, April 24, 1906.

SEE Eng. Pat. 14,239 of 1905; this J., 1905, 1110.—T.F.B.

FRENCH PATENTS.

Binding materials; Process of making hydraulic ——. M. Reiche. Fr. Pat. 360,518, Feb. 28, 1905.

SEE Eng. Pat. 4194 of 1905; this J., 1906, 316.—T. F. B.

Alumed sulphates of lime; Manufacture of —— at an accelerated rate. L. A. E. Taté. Fr. Pat. 360,035, Dec. 2, 1905.

CALCIUM sulphate, whilst being "alumed," is mixed with sulphate of sodium, potassium, or zinc, &c., and the mixture is furnaced at a temperature of from 800° to 1200° C. An already alumed plaster may receive an addition of one or other of the salts mentioned, followed by the necessary heating.—E. S.

Building material; Process for the manufacture of agglomerated ——. A. A. Queval. Fr. Pat. 360,446, Dec. 9, 1905.

THE essential feature of the invention consists in using as binding material a mixture containing an insoluble sulphate and an oxychloride. The binding material is formed by mixing together a solid composition and a liquid composition, which react to form simultaneously an insoluble sulphate, preferably lead sulphate, and an oxychloride of zinc, magnesium or aluminium. The binding material is then added to the substances to be agglomerated (soil, gravel, powdered stone waste, sawdust, slag, &c.), and the mixture moulded into the desired form. —A. S.

X.—METALLURGY.

(*Continued from page 432.*)

Blast-furnace; Balance-sheet of the ——. J. W. Richards. Electrochem. and Metall. Ind., 1906, **4**, 129—132.

A FURNACE at Herräng is run on ore briquettes, using charcoal as fuel and limestone as flux. The analyses of ore, flux and fuel are:—

	Ore.	Limestone.	Charcoal.
Fe_2O_3	85·93	0·18	0·32
FeO	3·96	—	C 80·31
SiO_2	5·50	3·14	0·19
MnO	0·63	—	N 0·08
Al_2O_3	0·76	0·32	O 3·54
CaO	2·23	53·74	0·89
MgO	0·97	0·17	0·10
P_2O_5	0·006	0·006	0·0068
S	0·010	0·001	0·0170
Cu	0·007	CO_2 42·42	H_2O 14·04
			K_2O 0·50

The pig-iron contains phosphorus, 0·012; sulphur, 0·007; manganese, 0·025; silicon, 0·60; carbon, 2·70; iron, 96·656 per cent. The charge is, ore, 1190 lb., flux 90 lb., fuel 530 lb.; and the fuel consumption is 682 lb. per 1000 lb. of pig-iron. The furnace gases (dry) contain nitrogen, 57·3; carbon monoxide, 23·1; carbon dioxide, 14·8; hydrogen, 4·3; methane, 0·5 per cent. Assuming the blast to be dry, and the flue-dust to be negligible, there are required: (1) A balance sheet of materials entering and leaving the furnace per 1000 lb. of pig-iron; (2) the percentages of the iron, manganese, silicon, sulphur and phosphorus entering the furnace which go into the pig-iron.

The balance-sheet is shown below. There are given, in the first place, the amounts of the various constituents in the weights of ore (1530·2 lb.), flux (115·8 lb.), and fuel (682 lb.) charged per 1000 lb. of pig-iron, together with the amount of air in the blast calculated as shown below:—

Charges.		Pig iron.		Slag.		Gases.	
Ore—

Pig-iron.—The ferric oxide of the ore yields 920·4 lb. of iron, so that 46·2 lb. are wanted to make up the 966·6 lb.

it contains; this is assumed to come from the ferrous oxide of the ore, of which it takes 59·4 lb. The remainder of the iron in the ore, and all that in the flux and fuel, are, therefore, assumed as going into the slag as ferrous oxide. The 6 lb. of silicon in the pig take 14·6 lb. of silica from the ore; the rest, with the silica of flux and fuel, goes to the slag. The manganese in the pig comes from the ore, and the rest of the manganese of the ore goes to the slag as manganese protoxide. The same applies to the sulphur, the surplus of which forms calcium sulphide with 0·14 lb. of the lime in the ore, and sends the equivalent oxygen into the gases. The phosphorus from every source is barely enough to furnish that contained in the pig-iron, so the whole is assumed as going there; the copper also goes to the pig-iron, though not mentioned in the analysis. The carbon in the pig-iron comes from the fuel.

Flux and fuel.—All the constituents of these not already accounted for go direct into the slag (the sulphur as calcium sulphide, and the equivalent oxygen to the gases) except the carbon, which goes into the gases.

Blast.—The total carbon in the gases is 534·09 lb. (13·39 from the flux, 520·70 from the fuel). The carbon per *volume* [100 galls., bearing same relation to cb. m. that lb. does to kilo.] is, from analysis of the gases 0·20736 lb.; hence gas per 1000 lb. of pig-iron is 2575·6 *vols.* This contains 1475·9 *vols.* of nitrogen, weighing 1859·6 lb. Of this, the fuel supplies 0·5 lb., leaving to be supplied from the blast 1859·1 lb., and equivalent oxygen 557·7 lb.

The total iron in the charge is 969·2 lb., and that in the pig-iron 966·6 lb., or 99·7 per cent. The corresponding figures are for manganese, 7·4, 0·25, 3·4 per cent.; silicon, 41·6, 6·0, 14·4 per cent.; sulphur, 0·270, 0·07, 25·9 per cent.; phosphorus, 0·063, 0·12, 100 per cent. (the excess of phosphorus in the pig arising either from analytical errors or from segregation). J. T. D.

Blast-furnace obstructions, Use of oxygen in removing ——. C. de Schwarz. Iron and Steel Inst., May, 1906. [Advance proof.]

When a taphole closed up with iron is to be opened, the iron is first heated with an oxyhydrogen flame supplied from a properly constructed "burner," the supply of hydrogen is then turned off and oxygen alone is supplied under a pressure equal to 30 atmospheres, whereby the iron is very soon pierced. The electric current may be employed for the initial heating. J. H. C.

Steel test-pieces; Relation between type of fracture and micro-structure of . C. O. Banister. Iron and Steel Inst., May, 1906. [Advance proof.]

The author finds that there is a distinct relation between the nature of fracture and the micro-composition of steel, and that valuable conclusions may be drawn from the examination of the fractured surface. Cup-fractures are obtained with homogeneous, minutely crystalline, or granular steel free from flaws of slag and manganese sulphide. Laminated fractures always contain slag lines or minute "ghost lines" consisting of manganese silicate, usually accompanied by manganese sulphide, running in parallel straight lines in the same direction as the laminations. Steels giving very irregular fractures are generally inferior in quality and made up of irregular patches of pearlite and ferrite, mostly accompanied by slag-lines or "ghost lines" running in various directions, and sometimes curved "ghost lines" are formed by segregations of carbon, sulphur, and phosphorus accompanied or not by considerable quantities of silicon and manganese. Crystalline fractures show a distinct relationship between the size of the crystals and the micro structure of the steel, and when slag and manganese sulphide patches are present in these, they are arranged in the ferrite bands around the pearlite. Oblique fractures are frequently varieties of laminated fractures, and where laminations are entirely absent there are often indications that rupture occurs in the direction in which the ferrite bands are best developed. Although laminated fractures are always associated with slag lines or "ghosts," yet coarsely crystalline steels containing "ghosts" do not always give laminated fractures. The prevalence of manganese sulphide and manganese silicate in commercial steels fully justifies their being classed as important constituents. Stereoscopic photographs (25) are given in illustration of the several kinds of fracture.—J. H. C.

Steel sheets; Brittleness and blisters in thin ——. E. F. Law. Iron and Steel Inst., May, 1906. [Advance proof.]

The author's experiments show that (1) oxidised steel gives rise to blistered sheets, and that this defect is more liable to occur with Bessemer than with open-hearth steel; (2) steel high in sulphur and phosphorus will cause brittleness in sheets, especially if the sheets are rolled from large and slowly-cooled ingots, in which the maximum of segregation has taken place.—J. H. C.

Steel; Effect of copper in ——. F. H. Wigham. Iron and Steel Inst., May, 1906. [Advance proof.]

In the first series of trials open-hearth steel was melted and poured upon cold ingots of copper contained in a separate ladle. In other cases the copper with a little aluminium was added to the steel as it ran into moulds. The author finds: (1) Copper is very difficult to alloy with steel so as to obtain a homogeneous mass containing over 2 per cent., even with the addition of aluminium. (2) Steel alloyed with copper in the pure form with the addition of aluminium is not so perfectly mixed as it is when the copper is added to the charge of steel in the furnace, and more copper could safely be employed provided it was in the metal before the latter was completely converted into steel. (3) In steel containing 0·5 per cent. or more of carbon it is not of practical value to use more than 0·6 per cent. of copper. (4) Steel with 0·25 per cent. of copper and alloys up to 0·25 per cent. of copper with high carbon (say, 0·70 per cent.) give, with or without a high percentage of manganese, a good quality of wire. In conclusion, it may be considered as proved that copper to the extent of 0·25 per cent. is no disadvantage in the manufacture of the best classes of steel wire.—J. H. C.

Ferro-molybdenums; Properties of pure —. E. Vigouroux. Comptes rend., 1906, **142**, 928–930.

For the method of preparation, see this J., 1906, 429. The following alloys are described: The alloy, Fe_2Mo, can be separated by means of dilute hydrochloric acid from alloys containing less than 46 per cent. of molybdenum. It is a grey metallic non-magnetic substance of sp. gr. 8·9. It is acted on by chlorine slowly at ordinary temperatures and very rapidly above 250° C. It is not attacked by hydrofluoric and hydrochloric acids or by dilute sulphuric acid, but is completely dissolved by hot concentrated sulphuric acid or by nitric acid. The alloy, Fe_3Mo_2, was obtained by the treatment of alloys containing between 46 and 54 per cent. of molybdenum with 30 per cent. hydrochloric acid. It is non-magnetic, has a sp. gr. 9·16, and has similar properties to the compound Fe_2Mo. The alloy, FeMo, extracted from alloys containing 54–63 per cent. of molybdenum, after treatment with still stronger acid or with hot solutions of cuprous chloride in hydrochloric acid, has a sp. gr. 9·01. It becomes incandescent in chlorine at 285° C. and is completely dissolved by iodine solutions, hot concentrated sulphuric acid, nitric acid, or when fused with potash. The alloy, $FeMo_2$, has a sp. gr. 9·41. It is extracted by treating alloys containing 64–77 per cent. of molybdenum with hot solutions of cuprous chloride in concentrated hydrochloric acid. It becomes incandescent in chlorine at 305° C. and in oxygen at 350° C. Sulphur is without action, and iodine only attacks it slowly. Acids have the same action as on the other alloys.—E. F. A.

Gold; New solvent for —. J. Moir. Chem. Soc. Proc., 1906, **22**, 105.

The author has found that gold-leaf dissolves fairly readily when floated on an acid solution of ordinary thiocarbamide. The action becomes rapid when a suitable oxidising agent is added. For example, when a solution of thiocarbamide is acidified and treated with a little ferric chloride, potassium dichromate, or hydrogen

peroxide, the mixture dissolves gold-leaf after less than a minute's shaking. The solution is not precipitated either by ferrous sulphate or by stannous chloride (except after long standing), whence it follows that the gold is present in solution as part of a complex ion. The gold compound is identical with a compound which the author has obtained by boiling a mixture of sodium aurichloride and thiocarbamide solutions.

Thorium silicide and a thorium-aluminium alloy. O. Hönigschmid. Monatsh. Chem., 1906, 27, 205—212.

THORIUM silicide is best obtained in quantity by the reduction of a mixture of potassium-thorium fluoride and potassium fluosilicate with aluminium in the electric furnace. A regulus of aluminium containing the crystalline silicide remains in the crucible, and the crystals are obtained free from aluminium and excess of silicon by boiling with caustic potash and then with dilute hydrochloric acid. It resembles graphite in appearance, crystallising in quadratic lamellæ of sp. gr. 7·96. Its composition corresponds to the formula $ThSi_2$. Chemically it behaves very like a metal, being unaffected by hydrogen, but combining with oxygen and the halogens on heating, and dissolving in acids. It is also formed by the direct union of thorium and silicon in presence of aluminium at 1090° C., and by the reduction of thorium oxide by silicon in the electric furnace.

A crystalline alloy of thorium and aluminium results when the two metals are heated together at about 1090° C. in a vacuum, the same compound being also produced by the reduction of thorium oxide or potassium-thorium fluoride by aluminium. The alloy crystallises from the aluminium regulus in hexagonal needles. It has the colour and appearance of aluminium, but is not attacked by aqueous solutions of the alkalis. Analysis shows it to have the formula $ThAl_3$.—F. SODN.

Platinum; Russian ——. Chem. and Drug., May 5, 1906.

ACCORDING to the official "Commercial and Industrial Gazette," the Ministry of Trade and Industry proposes shortly to summon a special conference to consider the questions of (1) the prohibition of the export of raw platinum, (2) the imposition of an export-duty, and (3) the construction of Government works for refining platinum. [T.R.]

ENGLISH PATENTS.

Refractory ores; Preliminary treatment of ——. L. V. Atkinson, Carshalton, Surrey. Eng. Pat. 28,932, Dec. 30, 1904.

THE invention deals with refractory ores containing iron, copper, silver and gold. It consists in roasting the crushed and concentrated ore at a temperature below redness in an atmosphere of steam, so as to convert the iron, but not the copper, into the form of sulphate. The iron sulphate formed is then leached out by hot water, after which copper is recovered either by electrolysis or by treatment with sulphuric acid, gold and silver being extracted as usual.—A. G. L.

Arsenic; Collection of —— in the treatment of refractory ores. L. V. Atkinson, Carshalton, Surrey. Eng. Pat. 28,992A, Dec. 30, 1904.

A PIPE sloping upwards and communicating with several openings in the roof of the furnace carries the arsenical fume into a condenser in which the arsenic is deposited on loose blankets supported on wire beds. Close to the furnace the pipe is provided with a down-take, consisting of a pipe of greater diameter than the up-take, or of a wide hopper. The lower end of this down-take fits over a sump placed above a fire-grate. In this sump are collected any particles of ore, &c., mechanically carried up by the fume, whilst any arsenic deposited with the impurities is again volatilised by the heat from the fire below the sump.—A. G. L.

[Gold, silver and copper] Ores; Treating ——. W. A. Hendryx, Los Angeles, Cal. Eng. Pat. 1916, Jan. 31, 1905.

THE ore is first put through a chemical preparatory treatment, which consists in the formation of a chemical ore-pulp solution in the ore grinding machinery, which solution prepares the ore for amalgamation and for electrolytic action; as much as possible of the metals is next recovered by amalgamation and electrolytic action, after which the ore is allowed to settle and classify, the solution being used over again, after removal of any compounds which would interfere with the solvent action of the cyanide. The ore-pulp is then further treated with cyanide solution or other chemicals, whilst at the same time moving continuously in a very thin conical-shaped stream in direct contact with the atmosphere, an electric current being also passed through the liquid from suitably-placed electrodes.—A. G. L.

Brazing metals. L. R. Schaap, Denver, U.S.A. Eng. Pat. 8307, April 18, 1905. Under Int. Conv., April 18, 1904

Copper nickel matte; Process of refining ——. N. V. Hybinette, Westfield, U.S.A. Eng. Pat. 24,486, Nov. 27, 1905.

SEE U.S. Pat. 805,555 of 1905; this J., 1906, 26.—T. F. B.

Zinc and other metals; Process of refining ——. J. Callmann and R. Bormann, Berlin. Eng. Pat. 3252, Feb. 10, 1906. Under Int. Conv., March 20, 1905.

THE zinc to be refined, or zinc waste, &c., is run in the molten condition into an inclined pipe filled with fragments of refractory material or of coal. The upper end of this pipe is kept at a temperature not much above the melting-point of zinc; the lower end is above the boiling point of zinc, and communicates either with a receiving vessel for the impurities, or else with a retort also kept at a temperature above the boiling point of zinc. The metal is run into the pipe at such a rate that it distils off during its passage down the pipe, leaving the impurities, which flow either into the receiving vessel or into the retort, in which the last of the zinc distils off, whilst the impurities are tapped off from an opening near the bottom of the retort.—A. G. L.

UNITED STATES PATENTS.

Ores of the precious metals; Process of treating ——. A. C. Atwater, Manchester, Iowa. U.S. Pat. 817,411, April 10, 1906.

ORES containing precious metals and selenium are mixed with a suitable proportion of a carbonaceous material (say from 1 to 10 per cent.), heated to a temperature sufficient to volatilise the selenium, and then allowed to cool, the heating and cooling operations being carried out with exclusion of air.—A. S.

Ores; Process and furnace for reducing ——. H. F. Brown, Chicago, Ill. U.S. Pats. 817,414 and 817,415, April 10, 1906.

THE furnace consists essentially of a down-draught stack connected at the bottom to a reverberatory fore-hearth. The stack has an ore-feed inlet at the top and then in turn a preliminary heating chamber, enlarged upper and lower combustion chambers with a narrow passage between them, and a heat-concentrating chamber of smaller cross-section than the lower combustion chamber. The finely-divided mixture of ore and slag-making impurities is fed into the preliminary heating chamber, and descends to the combustion chamber, into which by means of a burner projecting into the chamber "at an angle to the centre thereof," a whirling reducing atmosphere is directed. The reduced ore and slag and the gaseous products pass through the heat-concentrating chamber into the reverberatory fore-hearth, in which a molten protecting layer, *e.g.*, of slag, is maintained above

the molten metal, and separation of the metal and slag takes place by gravity. The gases from the fore-hearth are led through a regenerative chamber and thence to the receptacle in which the ore is stored, in order to dehydrate the ore. Air is also passed through the regenerator and thence to the burner, and to the space above the fore-hearth, where it mingles with and furthers the combustion of the reducing gases from the stack.
—A. S.

Metallic compounds; Manufacture of ——. S. Parfitt, Cardiff. U.S. Pat. 818,044. April 17, 1906.

SEE Eng. Pat. 2612 of 1903; this J., 1904, 22.—T. F. B.

FRENCH PATENTS.

Copper-aluminium alloys. A. C. Incagnoli. Fr. Pat. 360,250. Feb. 17, 1905.

(1) COPPER, 100·00; aluminium, 5·16; silver, 0·40; tin, 0·20. (2) Copper, 100·00; aluminium, 11·10; silver, 0·205; iron (malleable), 0·869. (3) Copper, 100·00; aluminium, 11·111; silver, 0·276; iron (malleable), 0·255.—J. H. C.

Aluminium alloys; Process for improving the quality of —— by heating to redness and tempering. C. Claessen. First Addition, dated Nov. 17, 1905, to Fr. Pat. 358,028 of Sept. 25, 1905 (this J., 1906, 185).

THE heating to redness and tempering are effected within the range of temperature limited on the one hand by a temperature 10° below the solidifying point of the alloy, and on the other hand, by a temperature, characteristic for each alloy, indicated by a break in the cooling curve; this lower temperature may be overstepped by about 30° C.—A. S.

Aluminium; Process for soldering or brazing ——. A. Proisy. Fr. Pat. 360,707. March 8, 1905.

THE solder is prepared by mixing together 700 grms. of zinc and 300 grms. of aluminium which have been fused separately, and then adding about 50 grms. of tallow, the mixture being heated and agitated until a homogeneous mass is obtained, which is cast into rods. The proportions of zinc and aluminium may be varied, and the melted solder is also preferably mixed with about one-tenth of its weight of silver-brazing. The pieces of aluminium to be joined are cleaned, coated with a solution of copaïba balsam, and then soldered in the usual manner.
—A. S.

Furnaces; Arrangements for the controlling the temperature of fusion ——. L. Pilla. Fr. Pat. 360,094, Dec. 5, 1905.

THE temperature of the fusion bath or crucible is determined and controlled by a current of water which, after becoming heated by circulating within a belt which surrounds the furnace, flows into a collector furnished with a thermometer.—J. H. C.

Furnace for metallic concentrations. International Metal Co., Ltd. Fr. Pat. 360,328, Dec. 11, 1905. Under Int. Conv., Dec. 14, 1904.

THE furnace is especially designed to volatilise and collect the metallic fumes arising from the heating of mixtures of ores of zinc or lead, crude or calcined, with combustibles. The mixture is introduced by a side door into a trough-shaped furnace having an opening in the bottom, the size of which can be regulated as required, and which is kept cool by currents of water or air. The fumes as formed are drawn off by an aspirator and collected in chambers.—J. H. C.

Gun-barrels and other metallic objects; Composition for cleaning ——. Saponia-Werke F. Boehm. Fr. Pat. 360,500. Dec. 15, 1905.

THE composition claimed consists of an intimate mixture of a saturated alcoholic solution of caustic soda, with a semi-liquid hydrocarbon, as, for example, a mixture of solid and liquid paraffins.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 433.)

(A.)—ELECTRO-CHEMISTRY.

Electrolysis with alternating currents. I. Electrolysis of alkali chlorides. A. Coppadoro. Gaz. chim. ital., 1906, **35**, 604—628.

IN electrolysis with alternating currents, the reactions are, according to the author, more complex than is usually supposed. For example, in the electroylsis of potassium chloride solution, immediately after the current has been started, potassium, chlorine, hydroxyl, and hypochlorous ions are present in the solution, and the formation of chlorate ions becomes possible. In the author's experiments, an alternating current of 42 periods per second was used, with platinum electrodes. With 3N solutions of potassium chloride and sodium chloride at temperatures between 15° and 30° C., no appreciable decomposition is produced with current densities below 50 ampères per sq. dcm.; with higher current-strengths, a tolerably considerable quantity of hypochlorite is formed. The gas produced consists of hydrogen; after a time, some oxygen is evolved, whilst chlorine is formed in traces at first, but later, not at all. In certain cases after the current has been passing for some time, the formation of chlorate is observed. The platinum electrodes are attacked and partly dissolved. In potassium chloride solutions, a deposit of platinum black and potassium platino-chloride is formed, and in sodium chloride solutions, one of pure platinum black. If the current density be not too high, the electrodes become platinised, and if the coating be perfect, the evolution of gas ceases, and also the amount of hypochlorite no longer increases. The platinum black decomposes hypochlorite with formation of chloride and oxygen. When the electrodes become platinised, the P.D. sinks appreciably owing to diminution of the polarisation.

With graphite electrodes, it is necessary to use a current-density of over 1000 ampères per sq. dcm. in order to obtain an appreciable production of hypochlorite. Graphite electrodes are also attacked.—A. S.

ENGLISH PATENTS.

Electrodes for electrolytic apparatus [*Hypochlorites, &c.*]. F. W. Howorth, London. From the heirs of the late C. Kellner, Vienna, Austria. Eng. Pat. 24,538, Nov. 27, 1905.

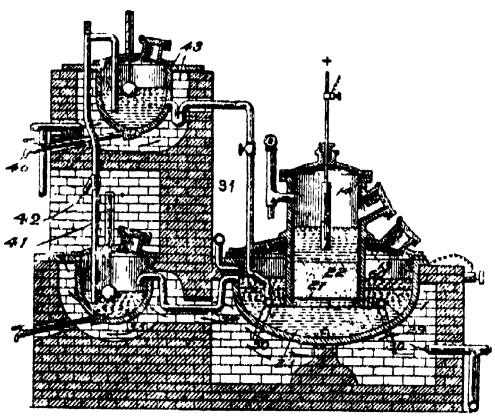
THE electrodes described are designed for use in the manufacture of substances, *e.g.*, hypochlorites, produced by the interaction of the cathode and anode products, and which must be protected from further oxidation or reduction. To this end the electrodes are made in the form ⊓, or ⊓|⊓, the last being designed to bridge over the low division walls of the electrolytic cell. The upper part of each electrode acts as cathode, the lower as anode. The electrolyte is circulated above the cathode in a direction parallel to the electrodes, the cathode thus preventing the further oxidation at the anode of the product of the reaction, which is formed in the layer of liquid between the two electrodes. The electrodes may be made solid or in lattice form.—A. G. L.

Ceramic ware; [*Electroplated* ——]. S. Heller, C. Baumgartl and Porzellanfabr. Ph. Rosenthal and Co., A.-G., Filiale Kronach. Eng. Pat. 10,833, May 24, 1905. VIII., page 478.

UNITED STATES PATENTS.

Batteries; Process of treating alkaline storage ——. T. A. Edison, Llewellyn Park, N.J., Assignor to Edison Storage Battery Co., West Orange, N.J. U.S. Pat. 817,162, April 10, 1906.

THIS invention relates to a process of treating, prior to shipment, an alkaline storage battery, the negative mass



of which contains, when charged, finely-divided iron and metallic mercury. The negative mass is completely discharged by means of a "reversing-current," so as to fully oxidise the mass and prevent atmospheric oxidation. —B. N.

Furnace; Electric ——. J. F. Hammond, Brewster, N.Y. U.S. Pat. 817,767, April 17, 1906.

THE furnace comprises a muffle wound on the inside with a heat-generating wire, *e.g.*, of platinum, and contained in a casing, which is provided on the outside with grooves, and rows of separators registering with the grooves. A resistance wire, for instance, of nickel, is disposed in the grooves between the separators, and is so bent that the bend of one convolution lies within the bend of another. The heat-generating wire and the resistance wire are connected together and one wire is connected with a device for varying the resistance, consisting of a rotary shoe which travels along the bends of the resistance wire, contacting with one bend before breaking contact with another. The whole is enclosed in an outer casing.—A. S.

Caustic alkali; [Electrolytic] Apparatus for and process of producing ——. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pats. 809,085 and 809,088, Jan. 2, 1906.

THE electrolytic vessel, 1, contains a liquid-metal cathode,

23, such as molten lead, and into this dips the anode-chamber, 14, containing a molten alkali salt, such as sodium chloride, the electrolyte being separated from the lead cathode by a diaphragm, 22, of granulated magnetite. The latter is prevented from dropping out of the anode-chamber by the wire-gauze disc, 21. The lead-sodium alloy collecting below the diaphragm is displaced from contact with the electrolyte and rises to the surface of the lead around the anode-chamber, the level of the metal in the anode-chamber being lower than the surface of the lead in the space surrounding the chamber. Molten caustic soda is injected in a number of fine streams into the molten alloy by means of perforations, 30, in the annular pipe, 29, thus producing sodium oxide, the oxidation being facilitated by a loose layer, 60, of granulated material, such as magnetite. The sodium oxide is drawn off through the inverted siphon, 34, into the vessel, 35. The oxide may be run off from this vessel, or forced by means of a steam injector, 42, through the pipe, 41, into a vessel, 43, thus forming caustic alkali, which is run off through 46, or through the pipe with siphon bend higher up to supply the hydroxide necessary to oxidise the sodium in the alloy in 1. When mercury is used as the cathode, an aqueous solution of the salt is used as the electrolyte, and water is placed on the surface of the cathode around the anode-chamber. Carbon electrodes also dip into this liquid to assist in the solution of the sodium. Water or dilute caustic soda solution is injected in place of the molten salt through the pipe, 29.—B. N.

Caustic alkali; [Electrolytic] Process of making ——. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 809,089, Jan. 2, 1906.

A LIQUID metal, such as mercury, is automatically supplied as required to an electrolytic cell containing a saturated solution of an alkali salt, the alkali metal being liberated in contact with the mercury. The amalgam of decreased density accumulates on the surface of the cathode and passes by gravity into a separate oxidising vessel; caustic alkali is formed in the latter by electrolysis, and the mercury, depleted of the alkali metal, passes out, by gravity, from the oxidising vessel. The electrolytic and oxidising vessels are separated by an intermediate vessel in which the amalgam is covered with a non-conducting liquid, such as carbon tetrachloride, so that metallic connection is broken between the metal in the two cells. By providing means for heating the apparatus, molten lead may be used as the liquid-metal cathode in conjunction with a molten electrolyte, such as sodium chloride. —B. N.

FRENCH PATENTS.

Electric furnace with two electrodes and automatic deflection of the arc. C. Limb. Fr. Pat. 359,854, Feb. 4, 1905.

THE arc is maintained at the ends of two vertical and parallel electrodes by the action of an electric current traversing a conductor passing round the furnace. The principle is identical with that of the Jamin arc lamp, and is here applied to the electric furnace as utilised for various electro-thermal processes.—R. S. H.

Furnace for baking [carbon-] electrodes. C. Cuau. Fr. Pat. 360,326, Feb. 20, 1905.

CARBON electrodes formed from retort carbon mixed with tar, &c., are packed in a chamber between iron pipes, which communicate with the hearth of the furnace; through these pipes the hot gases ascend. The volatile matters which emanate from the heated electrodes are burnt at the top of the furnace by an auxiliary admission of air, after which the products of combustion, on their way to the chimney, pass down through the iron pipes and thus also communicate their heat to the electrodes. To prevent burning, the electrodes are covered with sand. —R. S. H.

Carbons; Process and apparatus for graphitising —— by incandescence. C. Cuau. Fr. Pat. 360,361, Feb. 21, 1905.

THE bar of amorphous carbon which is to be graphitised, is clamped at each end between hollow, water-cooled, metallic bodies, which serve as contact pieces for the electric leads. It is surrounded by bricks of refractory material, and the whole is placed in a chamber full of sand. A current of electricity is then passed through the bar, of sufficient intensity to raise it to the required temperature.—H. B.

Carbon for electric resistances; Process of preparing ——. Electric and Ordnance Accessories Co., Ltd., and E. G. Rivers. Fr. Pat. 360,284, Dec. 9, 1905.

POWDERED carbon is mixed with an alkali silicate solution which acts as an agglomerant. The mass is hardened by being exposed to a high temperature. In cases where a still harder material is required, the mass, after heating, is immersed in a dilute acid solution. The products so obtained are suitable for use as resistances for electric radiators, for which purpose the paste can be spread upon refractory supports before heating. It is claimed that the product is of greater uniformity and higher specific resistance than the more usual types of carbon resistance. —R. S. H.

Charge of uniform composition in electric fusion or heating processes; Production of a ——. F. A. Kjellin. Fr. Pat. 359,998, Dec. 2, 1905. Under Int. Conv., Aug. 14, 1905.

AN alternating current traversing a conductor tends to concentrate itself near the surface, and in considering the heating effect of the current the temperature is higher on the surface than in the inside of the conductor. Inconvenience is caused in such cases where uniformity in the

heating is necessary. It is claimed that the distribution of temperature can be made much more uniform by employing alternating current of low frequency in place of that of 20—50 periods usually adopted. The number of periods per second should not exceed a value obtained by dividing double the specific resistance of the conductor (measured in ohms per m. of 1 sq. mm. cross section) by the cross section of the conductor (measured in sq.m.).—R. S. H.

(*B.*)—ELECTRO-METALLURGY.

Copper deposition; Action of organic colloids upon electrolytic —— [Brilliant deposits]. E. Müller and P. Bahntje. Z. Elektrochem., 1906, **12**, 317–321.

THE authors have investigated the effect of the addition of small quantities of colloidal solutions to the ordinary acid copper sulphate solutions used in electrolytic deposition. Gelatin, egg albumin, gum and starch were employed. Only in the two first instances was the character of the deposit materially altered. With gelatin the copper deposit with a current density of 0·0033 ampère per sq. cm. exhibits numerous vertical bright bands or stripes, just as though molten metal had flowed down the plate, solidifying on its way. If the current density be increased, the bands become wider, and with 0·035 ampère per sq. cm., provided the quantity of gelatin present be not too great, brilliant, quite homogeneous deposits of high reflecting power are obtained.

The above values for the current refer to the ordinary temperature of the room; increase of temperature has the same effect as a lowering of the current density, so that in warm solutions it is necessary to use a higher current density to obtain bright and even deposits.

The concentration of the sulphuric acid between N/1 and N/100 has little influence provided hydrogen be not evolved on the cathode surface.

Egg albumin has a less marked influence upon the deposit, the first effect being to produce a surface covered with innumerable small bright nodules.

To insure the satisfactory production of bright deposits it is in all cases essential to employ clear, well filtered solutions. The authors explain the observed phenomena by supposing that the bright deposit is formed by causing the metal to retain its amorphous condition and preventing it from becoming crystalline. The mutual protective effect of colloids upon one another, which has been noticed in other investigations, is probably the chief factor. Evidence in support of this hypothesis is adduced, as also in favour of the action of electrical endosmosis in transferring the colloidal mixture of the metal and organic substance to the cathode. Of some interest is the fact that only in acid solutions do the colloids give rise to bright deposits. The weight of copper deposited is greater than that obtained under normal conditions, owing to the presence of some 0·2 per cent. of the organic substance. The possible applications of the results are mentioned.

—R. S. H.

Chromium; Electrolytic production of metallic ——. O. Dony-Hénault and W. Gittens. Z. Elektrochem., 1906, **12**, 329–330.

WITH reference to the publications of Carveth, Mott and Curry (this J., 1905, 625 and 896) the authors mention experiments upon the electrolysis of chrome alum solutions, which lead them to consider that the conditions most suitable for the metal deposition are not necessarily the best for the preliminary treatment of the electrolyte for the purpose of improving it for the subsequent deposition of the metal.—R. S. H.

ENGLISH PATENT.

Cordite; Protection of steel guns from the erosive effects of ——, and similar gases. G. C. J. Topp, Isle of Wight. Eng. Pat. 12,635, June 19, 1905.

THE process consists in filling the gun with a suitable liquid, and electroplating the rifling with silver or other metal. It is claimed that erosion is thereby prevented, the plating alone being removed by the gases, and this can be renewed as often as necessary.—B. J. S.

UNITED STATES PATENTS.

Furnace; Electric ——. C. O. Wingren, Pasadena, Cal. U.S. Pat. 817,212, April 10, 1906.

THE furnace has a metallic air-tight casing, consisting of an outer body of heavy imperforate material with a removable cover secured to it, the cover being provided with a dome extending upwards. Electrodes are secured to, but insulated, from the body, and binding posts, which are fastened to the electrodes, project through the casing. Resistance material surrounds a smelting crucible placed between the electrodes, and the resistance material and electrodes are in turn enveloped by heat-insulating material. An observation tube is connected to the crucible, and, extending upwards through the heat-insulating material, terminates near the dome, a portion of the top of the latter being transparent. The dome is connected by a pipe to one of a number of ports in a valve-casing, a second and third pipe connecting the top and bottom of an air-pump, respectively, with two other ports in the valve-casing. Both these latter pipes are provided with clack-valves, the valve in the pipe connected to the top of the pump opening towards the latter and the other valve away from the pump. The piston of the pump has a check-valve opening in a downward direction. A valve-stopper in the valve-casing is provided with two channels, one being adapted to connect either of the pipes leading to the pump with the pipe leading to the dome, whilst the second channel simultaneously connects the other pipe from the pump with the outside air through ports in the valve-casing. The pump thus serves to exhaust the air from the crucible, or, after revolving the valve stopper, to put pressure upon the material in the crucible.—B. N.

Nickel-plating; [Electrolytic] Apparatus for ——. J. W. Aylsworth, East Orange, N.J., Assignor to Edison Storage Battery Co., West Orange, N.J. U.S. Pat. 817,152, April 10, 1906.

THIS invention relates to an apparatus for nickel-plating a continuous strip, and comprises a tank containing an electrolytic bath with a supporting beam carrying an upper and lower set of rollers, the latter being adapted to receive the strip alternately around the rollers of each set. Means are provided for raising and lowering the supporting beam, and for driving one or more rollers of the upper set, so as to move the strip through the bath, by means of a driving motor, the latter being connected by adjustable frictional connections with a supporting pulley mounted on the beam. A "take-up reel" is operated by the motor. Insulating bars for guiding the strip are carried by a series of hangers immersed in the bath. An "occluding-chamber," carried by the beam and normally partially submerged in the solution, and a cleaning tank in which the strip may be submerged are provided. The strip passes over an "idler," supported by a bracket on the beam, and removable brushes make contact with the strip on each side of the "idler." The strip is dried by passing it over two rollers, which are connected to the source of current, and by adjusting the rollers with respect to each other, the length of the heated section between the rollers may be regulated.—B. N.

Magnetic separation; Process of ——. F. T. Snyder, Oak Park, Ill., Assignor to International Separator Co., Chicago, Ill. U.S. Pat. 817,399, April 10, 1906.

A DIFFERENTIAL reciprocating movement is imparted to the ore within the influence of a magnet, which is periodically energised and de-energised, the reciprocating movement being so adjusted that the more permeable particles are attracted by the magnet and thus retarded, while the mass of ore is moving in one direction, but allowed to travel with the ore, while the latter is moving in the opposite direction. In this manner the magnetic particles are given a "net" movement in one direction and the non-magnetic particles a "net" movement in the opposite direction.—A. S

Iron and its alloys; [Electrical] Process of manufacturing ——. M. Ruthenburg, Lockport, N.Y. U.S. Pat. 818,918, April 24, 1906.

The ore in a comminuted condition is fritted into coherent porous lumps by the action of an electric current, the lumps are collected in a confined heated atmosphere and subjected to the action of a de-oxidising gas until they are reduced without being melted, and the reduced lumps are finally melted by passing an electric current through them.—A. S.

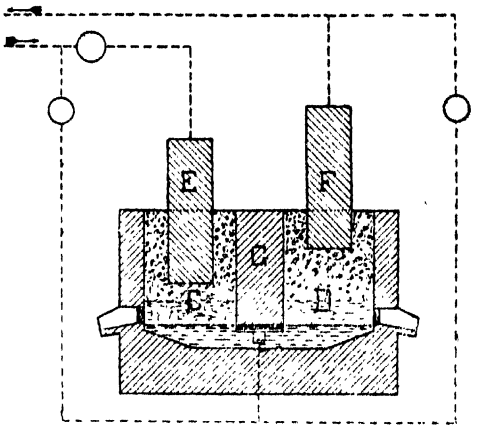
Gold and other valuable metals; Process of reclaiming waste —— from water and other liquids. C. E. Holland, Assignor to The Holland Metal Recovery Co., New York. U.S. Pat. 818,174, April 17, 1906.

The water or other liquid is led continuously into and through a "runaway" or tank, wherein it is subjected to electrolysis in the presence of a body capable of forming a congulum. The coagulum and precipitate produced by the electrolysis are removed, evaporated, the liquid separated by decantation or filtration, and the gold or other metal extracted from the residue by a suitable process.—A. S.

French Patents.

Steel mixer; Electric ——. Soc. Electro-Métall. Française. Fr. Pat. 360,072, Feb. 11, 1905.

An electric oscillating furnace, such as that of Héroult (this J., 1902, 1237), is modified and constructed on a larger scale to serve as a "mixer" for steel, and thus ensure uniformity in the production of large masses. The apparatus is intended to receive molten steel from other furnaces and maintain its temperature by sufficient expenditure of electric energy to compensate for the thermal losses due to radiation, &c. In order to obviate the possibility of oxidation by ingress of air, the furnace is made as gas-tight as possible, and is connected to a gas producer which maintains a slight positive pressure within the furnace. The carbon electrodes are supplied with water-cooled collars which make a gas-tight joint with the cover. For a mixer of 100 tons capacity the following dimensions are given: surface of molten metal, 26 sq. m.; depth of molten metal, 1 m. Two electrodes, for single phase current, each 95 × 95 cms. cross section and 5 m. long. Such a furnace, supplied with 2500 h.p., is stated to be capable of reheating 50 tons of molten metal per hour through 50° C.—R. S. H.



Copper; Extraction of —— from its ores [Electrolytically]. G. R. M. Sweeting. Fr. Pat. 360,071, Feb. 11, 1905.

The powdered sulphides are spread in a thin layer upon the sole of a reverberatory furnace moderately heated with coke, and in the presence of a quantity of air sufficient to supply 4 mols. of oxygen for each molecule of metal; the ore thus roasted is thrown into water contained in tanks of masonry whereby the copper is obtained in the state of sulphate solution, which is then evaporated until it reaches a proper density and finally submitted to electrolysis.—J. H. C.

Copper from its minerals; Electro-metallurgical process for the extraction of ——. L. Jumau. Fr. Pat. 359,913, Nov. 29, 1905.

The minerals are extracted with a solution of ammonia, preferably containing ammonium salts. The solution thus obtained is electrolysed directly, or the ammonia is recovered and the precipitated copper redissolved in acid and the solution submitted to electrolysis. The use of cuprous salts is preferred on account of the higher current yield, as also for the depolarising action of such solutions at the anode. The preparation of the cuprous salts can be effected by reducing the solutions with sulphurous acid. Finally, the ammonia is recovered by treating the residual liquors with lime. A subsidiary claim is made for an improvement in the diaphragms used in such a process. A porous material, *e.g.*, asbestos, is impregnated with gelatinous silica by immersion in a mixture of sulphuric acid and sodium silicate.—R. S. H.

Alloys; Production of —— in the electric furnace. M. Marchadier. Fr. Pat. 360,187, Nov. 11, 1905.

The method consists in treating separately and in suitable proportions the minerals of each metal entering into the composition of the alloy. The reduced and fused metals are mixed before their solidification or before they are tapped from the furnace. The electric furnace is divided into two compartments, C and D, by a refractory wall, G, reaching nearly to the bottom of the hearth. The current passes directly through the furnace from one electrode, E, to the other, F, but by regulating the potential in each half of the furnace, the relative expenditure of energy can be varied considerably, and thus the proportions of each metal required to form the alloy can be adjusted.—R. S. H.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 434.)

Enzyme action; Studies on ——. *Lipase.* M. Nicloux. Roy. Soc. Proc., 1906, **77** B., 454.

The following general results have been obtained in studying the hydrolysis of fats by castor oil seeds. (Compare H. E. Armstrong, this J., 1905, 1242). It is possible by mechanical means to separate the cytoplasm of the seed from the aleurone grains and all other cellular elements; the cytoplasm alone can hydrolyse fats, acting as an enzyme and following the laws of enzyme action; its activity is considerable. The author holds that this active substance, which is destroyed by water so soon as it is no longer protected by fats, is not an enzyme, and he terms it lipaseidine.—E. F. A.

Walnut oil; Detection of foreign oils in ——. P. Balavoine. XXIII., page 499.

English Patents.

Fats and the like; Apparatus for the recovery of ——. C. Kremer and Ges. für Abwässerklärung m.b.H., Berlin. Eng. Pat. 23,670, Nov. 17, 1905.

Claim is made for a combination of a number of the fat collectors described in Eng. Pat. 14,461 of 1903 (this J., 1903, 1095), fed by a common pipe and contained in a common vessel open to each of them, so that there is a uniform current upwards and downwards, and a consequent uniform separation of fat and solid matter. All the lower edges of the walls of the fat collectors and the edges of the overflow channels may be made in a zigzag or serrated shape, so that any slight deflection of the partitions, &c., by the force of the water may not interfere with the even distribution of the liquid.—C. A. M

Soap solutions; Process and apparatus for cooling ——. F. Jürgens, Sangerhausen, Germany. Eng. Pat. 18,666, Sept. 15, 1905.

Very rapid cooling of the soap may be effected by exposing the hot solution to the action of a vacuum, whilst the walls of the vessel are meanwhile scraped with knives or scrapers. In the apparatus claimed for this process, the hot soap is introduced into a conical vessel surrounded by a cooling jacket, and having a central cooling tube, round which revolves a spiral provided on the outside and inside with scrapers which remove the solidifying soap from the wall of the cylinder and the surface of the inner cooling tube respectively. The agitation may be effected more thoroughly by making the cooling tube revolve in the opposite direction to the spiral. Nozzles are provided at the top for the exhaustion of air from the apparatus.—C. A. M.

United States Patents.

Detergent for scouring wool. S. Wohle, London. U.S. Pat. 818,648, April 24, 1906.

See Eng. Pat. 12,632 of 1904; this J., 1905, 671.—T. F. B.

Washing powders containing alkali peroxides; Vessel for packing and storing ——. J. von Königswarter, Hanover, Germany. U.S. Pat. 818,695, April 24, 1906.

See Eng. Pat. 19,809 of 1905; this J., 1906, 32.—T. F. B.

French Patents.

Olive oil; Apparatus for washing —— by decantation. V. Coq. Fr. Pat. 360,733, Dec. 21, 1905.

The apparatus claimed comprises a battery of conical decantation vessels contained in a chamber heated inside by a steam coil or otherwise, and fed by a single pipe which conveys the impure oil and the water for washing it. The separated liquids pass from the bottom of the vessels into funnels with three-way cocks communicating with separate pipes intended for the water, the *crasse*, and the pure oil respectively.—C. A. M.

Soap, ointment or paste for disinfecting purposes; Process of making ——. [*Peat tar.*] J. Kessler and Co. Fr. Pat. 360,174, Dec. 7, 1905. XVIIIC., page 493.

German Patent.

Resin soaps; Process for the removal of the resin colouring matter from ——. H. Schladitz. Ger. Pat. 167,240, June 12, 1904.

The process consists in adding before, during or after saponification of the resin, a solution of common salt, of such concentration that it will, together with the dissolved impurities, form a separate layer above the resin soap. For example, 100 parts of resin are saponified by 70—80 parts of a caustic soda lye of 25° B., in presence of 15 parts of common salt. Sufficient cold water is then added, with constant agitation, to form a salt solution of 3°—5° B. On allowing to settle, the salt solution, containing the resin colouring matter and other impurities, forms a separate layer above the resin soap, and can be removed. —A. S.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(*Continued from page* 435.)

(*A.*)—PIGMENTS, PAINTS.

Kermes mineral. Gabriel de la Puerta. Rev. Real. Acad. de Ciencias de Madrid, 1905, **3**, 269. Chem.-Zeit., 1906, **30**, Rep., 139—140.

A sample of Kermes mineral prepared from stibnite with sodium carbonate by Cluzel's method was found to contain, besides antimony sulphide, 20 per cent. of a mixture of sodium pyroantimoniate and amorphous antimony trioxide in about equal proportions. It also yielded 12·3 per cent. of water, indicating the presence of the sulphide as $Sb_2S_3.3H_2O$.

The following modified method is recommended for the preparation of a well coloured product:—10 grms. of finely powdered antimony sulphide, 50 grms. of crystallised sodium carbonate, and 1 grm. of sodium hydroxide, are boiled with 2 litres of water for about half an hour, until half the liquid is evaporated, the mass being kept well stirred. After allowing the filtrate to stand for 24 hours, the precipitated Kermes is filtered off, washed free from alkali, and then dried at 25°—30° C., and powdered. Yield, about 5 grms. On acidifying the mother liquor a precipitate of "golden antimony sulphide" (Sb_2S_5) is obtained.—F. Sodn.

French Patents.

Pigment, with zinc base, and process of manufacturing same. D. Lance and C. L. de Joannis. Fr. Pat. 360,215, Feb. 16, 1905.

The pigment consists of a mixture of zinc white and hydrated oxide of zinc, or of zinc carbonate and hydrated oxide, or of all three, and it is claimed that the properties of such a pigment, prepared as described, approximate to those of white lead, particularly as regards covering power and rapidity of drying. To prepare the pigment, ordinary (dry process) zinc white is subjected to a preliminary wet grinding in a tube-mill, in order to round off the edges of the angular particles, and is then mixed with a quantity of zinc hydroxide, prepared by a precipitation process in the cold or at a temperature of 50°—80° C. The proportions of the two compounds used are indicated by two general formulæ:—(1) $2ZnO + Zn(OH)_2$; (2) $6ZnO + Zn(OH)_2$, of which the first is a type of the composition of enamel pigments, the second being that of pigments suitable for matt surface paints. When the paint is required for use as a second coat for enamelling, and covering-power is not of primary importance, zinc carbonate may be substituted for a part or the whole of the zinc oxide. The superior drying properties of the pigment are conferred upon it by the hydrated oxide, which acts in a similar manner to hydroxide of lead, in partially saponifying the oil used as medium and so causing it to dry more rapidly.—E. W. L.

Zinc; Treatment of complex ores of ——. *Industrial preparation of zinc sulphite, and its application to forming a lithopone* [*paint*] *having barium sulphite as its base.* L. Brunet. Fr. Pat. 360,517, Feb. 28, 1905.

Zinc pyritic ores are so turnaced and the vapours treated with steam, as to yield zinc sulphite as a main product. To a solution of the zinc sulphite, solution of barium sulphide or hydroxide is added, to obtain as a precipitate a mixture of barium sulphite with zinc sulphide or with zinc oxide, which precipitate is applicable as a lithopone. —E. S.

Lakes [*from azo dyestuffs*]; *Process of making red* ——. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 360,824, March 13, 1905.

See Ger. Pat. 161,424 of 1904; this J., 1905, 1244.—T.F.B.

German Patents.

Lakes [*from azo dyestuffs*]; *Process of preparing red colour* ——. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 165,823, Aug. 20, 1904.

Lakes of a bright yellowish-red colour, and very fast to light, are obtained in the usual manner from the azo dyestuff prepared by combining β-naphtholdisulphonic acid R with diazotised dichloroanilinesulphonic acid, obtained either by nitrating *o*-dichlorobenzenemonosulphonic acid and then reducing, or by sulphonating 3.4-dichloroaniline.—T. F. B.

Paint, vehicle; Process for the manufacture of a ——. Norddeutsche Wollkämmerei u. Kammgarnspinnerei. Ger. Pat. 166,563, Dec. 1, 1904.

Colophony is saponified with a suitable metallic oxide, especially zinc oxide, or a mixture of zinc oxide and magnesia, then mixed with neutral wool-fat containing

a small quantity of the magnesia soaps of the wool-fat acids, and the mixture dissolved in a suitable solvent, *e.g.*, heavy coal-tar oil. The product is stated to be of use as a substitute for boiled linseed oil, being more resistant than the latter to the action of saponifying agents.—A. S.

(*B.*)—RESINS, VARNISHES.

Turpentine oil; Pinene fractions of French and American ——. B. Ahlström and O. Aschan. Ber., 1906, **39**, 1441—1446.

French and American turpentine oils were carefully fractionated, and determinations of density and specific rotation carried out on a large number of fractions boiling between 153° and 175° C.; the rotation of the hydrochloride from each fraction was also measured. The authors conclude that the pinene in these oils is mixed not only with pseudopinene, but with another or several other terpenes, which have a rotation opposite in sign to the contained pinene. By mixing inactive fractions of American and French oils, boiling at 155°—156° C., a lævo-rotatory hydrochloride was prepared. The oxidation of different fractions by a 1 per cent. solution of potassium permanganate gave varying amounts of nopinic acid, but little light was obtained in this way regarding the identity of the new terpenes. The authors suggest that cymene or limonene may be present and are continuing the work. —C. E. F.

Terpenes in Finnish crude turpentine. O. Aschan. Ber., 1906, **39**, 1447—1551.

The crude turpentines from fir and pine trees (*Pinus sylvestris* and *Pinus abies*) were distilled with steam and the turpentine oil so obtained fractionated. The turpentine oil from *Pinus abies*, as grown in Finland, contains *l*-pinene and probably *l*-limonene, but is free from sylvestrene. The oil from *Pinus sylvestris* contains *d*-pinene and *d*-sylvestrene.—C. E. F.

United States Patent.

Wood; Process of treating —— *for the production of paper pulp, terpenes and resinous substances.* G. P. Craighill and G. A. Kerr, Assignors to N. C. Manson, jun. U.S. Pat. 817,960, April 17, 1906. XIX., page 494.

(*C.*)—INDIA-RUBBER, &c.

Rubber; Relation between specific gravity and sulphur content of vulcanised Para ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 733.

The rubber used was a technical washed and dried Pará, containing 6·27 per cent. of resins and 0·27 per cent. of ash; 10-grm. samples were masticated with milk of sulphur in proportions varying from 5 to 75 per cent. of the weight of rubber, and cured, in glass moulds, by heating in an autoclave for 50 minutes at 145° C. and 4 to 5 atmospheres pressure of steam. The specific gravity at 16° C. of the vulcanised samples, determined by means of a pyknometer, varied from 0·834 with 5 per cent. to 1·130 with 75 per cent. of sulphur, but not uniformly with the sulphur content; it attained the value unity with a percentage of sulphur between 30 and 35.—E. W. L.

India-rubber; Effect of heavy magnesia as a filling material upon ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 760.

Para rubber was mixed with 10 per cent. of sulphur and rising percentages of heavy magnesia (magnesium oxide), and vulcanised for 45 minutes at 145° C. under a pressure of 4—5 atmospheres. The specimens were then tested mechanically. The breaking strain reaches a maximum at 30 per cent. of magnesia, and is throughout much greater than that of the same rubber similarly vulcanised without magnesia. The elasticity reaches a maximum at 25 per cent. of magnesia, and up to that point is considerably lower than that of the "blank." With more than 35 per cent. the mixing refuses to work coherently on the rollers.—W. A. C.

Rubber tree; New ——. For. Off. Ann. Ser., No. 3558.

A new kind of rubber tree, previously unknown in that part of Venezuela, has been discovered in the extensive forests of the Caura district, situated from 150 to 200 miles to the west and south-west of Ciudad Bolivar. Sample lots of the rubber produced from this tree have been sent to London, New York and Hamburg, and have realised from 3s. to 3s. 6d. per lb. This price is remunerative, as good facilities for transport by water exist. Unfortunately, as yet no efficient system of tapping the trees has been discovered, as by the method of tapping applied to the india-rubber trees in the Rio Negro district the milk does not exude freely. The consequence is that the collectors fell the trees to be able to tap them all along the trunk, following in this respect the system they employ for collecting balata. This, of course, will bring about the eventual exhaustion of the forests, which, in the case of the balata tree, is already beginning to be felt. [T.R.]

English Patent.

Caoutchouc, gutta-percha and balata; Process for the direct utilisation of the lactiferous juices of ——. L. P. T. Morisse, Paris. Eng. Pat. 7705, April 11, 1905.

See Fr. Pat. 360,325 of 1905; following these.—T. F. B.

French Patents.

Caoutchouc, gutta-percha and balata latices; Direct employment of —— *for manufacture of rubber articles.* L. Morisse. Fr. Pat. 360,325, Feb. 20, 1905.

The latex is poured on or into moulds, and is there coagulated by means of a suitable agent, as, for example, the following solution:—Beech-wood creosote, 2·5 grms.; guaiacol, 0·5 grm.; and alcohol, 50 grms. To this solution an amount, varying with the nature of the latex to be treated, of a solution of commercial sulphuric acid (25 grms. per litre), is added. One hundred and fifty grms. of the mixed solutions are sufficient to coagulate, sterilise and vulcanise a litre of latex, the vulcanisation being effected by the sulphuric acid. Balata and gutta latices need not be vulcanised.—E. W. L.

Rubber substitute, commonly called "Lynoxyne"; New application of the ——. A. E. Bretnacher. Fr. Pat. 360,090, Dec. 5, 1905. Under Int. Conv., Jan. 12, 1905.

Claim is made for the use of "Lynoxyne," prepared by heating oxidised linseed oil to as high a temperature as possible without decomposition—for the manufacture of articles in which its great elasticity under compression is of service, namely, cushions and buffers of various kinds. To utilise the substitute for this purpose, the mass, either hot or cold, is encased in various materials such as cloth, leather or rubber.—E. W. L.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 436.)

Hides; Depilation of —— *by the "sweating" process.* Palmer. Bull. Soc. chim. Belg., 1906, **19**, 280—281.

The "sweating" method for the depilation of hides consists of a superficial putrefaction, produced either by piling the hides in heaps which are covered with materials such as spent tan, straw, stable manure, &c., or else by placing them, previously moistened with water, in galleries in which a temperature of 22°—27° C. is maintained. In America the "sweating" is conducted at a temperature of 15°—21° C., by injecting a mixture of steam and atomised cold water into the chambers. The author's studies showed that ordinary methods of sterilisation cannot be applied to operations of this kind, and he had recourse to potassium xanthate, which has the advantage of restricting the development of the ordinary putrefactive bacilli, whilst favouring that of the bacteria which bring about the loosening of the hair. These bacteria are found in the form of rods and cocci,

always united in colonies and which are strongly stained by Methylene Blue. They show relationships with *B. subtilis* and *B. amylobacter*.

The author concludes that the depilation can be effected quite as well at a temperature of 17° C. as at 27° C., and there is less risk of damaging the hide at the lower temperature. The prejudicial action of darkness is less to be feared when depilation is conducted at a moderate temperature. Potassium xanthate does not act as an antiseptic but contributes to the formation of a medium favourable to the development of certain useful bacteria. The putrefactive bacteria are distinctly harmful. A microscopic examination is of great utility in following the course of depilation.—J. F. B.

French Patents.

Leather; New artificial ——. A. Sylvestre. Fr. Pat. 360,152, Dec. 7, 1905.

Felt is impregnated with a mixture of certain gums and resins by immersing it, at ordinary temperatures, in a preparation such as those described below, subjecting the wet mass to pressure, and, after allowing it to dry, passing it through warm calenders. As examples of the mixtures of gums and resins employed, the following are given:—

No. 1.		No. 2.	
Alcohol	100	Alcohol	150
Rosin	10	Mastic	30
Benzoin	40	Benzoin	40
Sandarac	15	Gomme nouvelle	15
Rubber	2	Rubber	2
Linseed oil	10	Benzine	20
		Linseed oil	10

It is claimed that the product obtained by this process is impermeable, supple and unbreakable.—E. W. L.

Leather; Artificial ——. H. Karle. First Addition, dated Nov. 17, 1905, to Fr. Pat. 342,622, April 25, 1904 (this J., 1904, 944.)

A solution of balata gum in benzene or other solvent is employed as a binding material for the fibrous layers described in the original specification. The balata gum may be partially replaced by other gums and caoutchouc. The treated sheets are then slightly tanned, calendered, dried, coloured and dressed. Gelatin may also be used as a binding material.—W. P. S.

German Patent.

Fibrous substances [textiles, leather, paper, &c.]; Process for waterproofing ——. Chem. Fabr. Flörsheim, Dr. H. Noerdlinger. Ger. Pat. 166,350, May 12, 1904. V., page 475.

XV.—MANURES, Etc.

(*Continued from page* 436.)

Calcium and magnesium salts; Influence of —— on certain bacterial actions. S. Machida. Bull. Imp. Centr. Agric. Experim. Stn., Japan, 1905, **1**, 1—12.

The experiments show that the putrefaction of urine and peptone is retarded by calcium salts, but facilitated by those of magnesium, whilst nitrification is favoured by magnesium carbonate to a greater extent than by calcium carbonate. Certain putrefactive bacteria, such as *B. fluorescens liq.*, *Proteus vulgaris* and *B. mycoides* are able to assimilate tricalcium phosphate, thus indicating the possibility of rendering insoluble phosphates in the soil available for plant food.—C. S.

Lime factor for the tobacco plant; On the ——. G. Daikuhara. Bull. Imp. Centr. Agric. Experim. Stn., Japan, 1905, **1**, 17—22.

The original soil contained almost identical quantities of lime and magnesia, and comparative trials were made with added lime to increase the lime factor to 2:1 and 4:1. The latter, which corresponds approximately with the mean ratio in the ash of various kinds of tobacco, gave the best results, the budding, flowering and topping being accelerated by twelve, nine and three days respectively. The size of the plant was increased, and the weight by about 43 per cent. With added fertilisers the highest yield was furnished by a mixture of ammonium sulphate, superphosphate and potassium carbonate.—C. S.

Magnesia; Application of —— in the form of magnesium sulphate for the needs of the rice plant. G. Daikuhara. Bull. Imp. Centr. Agric. Experim. Stn. Japan, 1905. **1**, 23—29.

To ascertain how much magnesium sulphate can safely be employed, as a source of magnesia, in place of magnesite (which is scarce in Japan), rice was grown in pots of sand treated with a uniform ratio of nitrogen: phosphorus pentoxide. The results showed that in presence of lime as carbonate the best ratio CaO:MgO, when magnesium sulphate is used, is 30:1 in place of 1:1 with magnesium carbonate. This applies, however, only to sandy soils. Sodium nitrate is found inferior to ammonium sulphate, in the ratio of 40:100, as a source of nitrogen for the rice plant.—C. S.

Magnesia; Improvement of a soil relatively deficient in ——. T. Nakamura. Bull. Imp. Centr. Agric. Experim. Stn. Japan, 1905, **1**, 30—34.

In a light soil containing lime and magnesia in the ratio 176:11, the lime being to a large extent in the form of silicate, the most favourable effect on barley was obtained by adding magnesium sulphate to modify the ratio to 7:1, the relative value of the sulphate to the carbonate (magnesite) being found to be about 23:100 in this instance. —C. S.

French Patents.

Phosphates [Bi-magnesium-hydrogen phosphate]; Manufacture of bibasic —— by means of natural phosphates. J. J. T. Schloesing. Fr. Pat. 360,357, Dec. 12, 1905. VII., page 478.

Manure; Manufacture of dry —— by means of organic waste matters. G. Gunther. Fr. Pat. 360,479, Dec. 14, 1905. Under Int. Conv., Dec. 28, 1904.

Waste organic materials, especially woollen rags, waste hair, horn, feathers, or leather, &c., are subjected for a few minutes, or longer, according to circumstances, to the action of a highly heated vapour or gas, or a mixture of such. The process may be conducted in any suitable apparatus, and superheated steam may be used as the desiccating agent. The product obtained is stated to be brittle and easily friable, and is applicable as a manure. —E. S.

Peat; Industrial treatment of —— to increase its contents of nitrogen, in view of its application as a manure. E. V. H. Bazin. Fr. Pat. 360,484, Dec. 14, 1905.

The object of the invention is to produce by the aid of blocks of peat, a *nitrière*, or nitrate-producing ground. On a paved or cemented space, having a slight elevation on one side, to permit of drainage towards a determined point, blocks of peat, cut to a convenient size, are stacked in piles, surmounted by perforated troughs from which a liquid continuously flows on to the peat. The drainage passes into a cemented cistern from which it is continuously pumped back to the troughs. The cistern is supplied with urine or ammoniacal liquids, such as may carry nitrate-producing bacteria, which are also preferably supplied to the liquid by the addition of leguminous plants. Directions are given for removal of the enriched heaps of peat, and their preparation for manurial application, and for their replacement by fresh heaps without disturbing the continuity of the process.—E. S.

XVI.—SUGAR, STARCH, GUM, Etc.

(*Continued from page* 438.)

Beetroots; Simplified filtration in the analysis of ——. Nyssens. Bull. Soc. chim. Belg., 1906, **19**, 285.

In order to avoid large quantities of glass funnels and receivers in the determination of sugar in beetroot pulps, when the number of samples is very large, the author employs small cups of enamelled iron, perforated at the bottom. A folded filter-paper is bound round the outside of the bottom of each of the cups, which are then floated in the clarified extract of beet-pulp prepared according to the Le Docte method, in the special capsules or cans generally employed. As the solution filters upwards into the cups, these sink, and a sufficient quantity of clear liquid can be siphoned off for polarisation in a very short time.—J. F. B.

Starch; Acid properties of ——. E. Demoussy. Comptes rend., 1906, **142**, 933–935.

Rice starch, demineralised by dilute hydrochloric acid and washed till free from chloride, has the properties of a weak acid comparable with carbonic acid and resembles in this respect the other carbohydrates (see Ford and Guthrie; this J., 1906, 228). It forms compounds with the metallic hydroxides, ammonia and the alkali carbonates, which are dissociated by water and it is also capable of absorbing small quantities of neutral salts, *e.g.*, chlorides of sodium and potassium, potassium sulphate, copper acetate, &c.—E. F. A.

Pentoses, New method for the quantitative determination of —. A. Jolles. XXIII., page 500.

English Patent.

Inulin; Process for the complete extraction of ——, *from the tubercles containing it.* I. De Vecchis, Rome, and A. Sam. S. Giorgio di Nogaro, Italy. Eng. Pat. 5323, March 5, 1906.

The tubercles are cut into small slices and thoroughly extracted with water at a temperature of from 80° to 85° C. in a diffusion apparatus. The extract is then heated to a temperature of 95° C. to coagulate the albuminoids, filtered, and evaporated under reduced pressure at 95° C. The thick syrup obtained is filtered while still hot through animal charcoal, and the filtrate allowed to cool, when the greater part of the inulin separates out. After removing the deposited inulin, the mother-liquor is again filtered through animal charcoal, evaporated to a pulp, cooled and at the same time stirred, and finally subjected to centrifugal action. A further quantity of inulin is thus obtained; as it has a slight brown colour it may be dissolved in a subsequent supply of the thick syrup before filtration.—W. P. S.

French Patent.

Saccharine juices; Process of carbonating ——. E. J. B. Portemont. Fr. Pat. 360,743, March 9, 1905.

The carbonating is effected in a series of closed vessels in which the treatment with the gas is continuous in all except the last. The juice enters the first vessel of the series and passes out, after treatment with carbon dioxide, from the bottom through a wide pipe entering the second vessel at the upper level of the liquid, and so on through the series until the last vessel is reached. The juice is admitted to the last vessel intermittently in determined quantities by means of screw valves in the bottom. The correct degree of carbonating is then established in this vessel, the rate of previous treatment having been such that this degree is reached in a very short space of time. The juice is then discharged and a further quantity is admitted. In each vessel an oscillating agitator is provided in order to effect a complete admixture between gas and liquid.—J. F. B.

German Patent.

Gum; Process for the preparation of a soluble vegetable ——. Gerson und Sachse. Ger. Pat. 167,275, Feb. 14, 1903.

Starch and substances containing starch are macerated with a 1 per cent. solution of caustic soda, and then treated with an easily decomposable oxidising agent until the product, after neutralising with acid and washing free from soluble salts, is soluble in boiling water and cold alkali solutions.—A. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

(*Continued from page* 440.)

Barley; Dependence of the extract yield on the protein content of ——. Stockmeier and Wolfs. Bayer. Brauerj., 1906, No. 13; Z. ges. Brauw., 1906, **29**, 252–254.

The authors have determined the extract contents of a large number of barleys of the current season. The barleys were ground first in a Seck's "fine grist" mill and were then finely powdered in a Dreef's mill; 25 grms. of the meal were then treated exactly in the manner prescribed by Graf (this J., 1906, 201) for the determination of the extract. In a table are given the values obtained for protein, extract, grading, weight per hectolitre and weight per 1000 corns for each of the 34 samples. The results showed, on the whole, that the extract contents diminish as the protein contents increase. The following summary of average results from the various groups, arranged according to the protein contents, illustrates this relation:—

Protein contents (dry barley)	Samples.	Mean protein contents (dry barley).	Mean extract contents (dry barley).

—J. F. B.

Hydrogen peroxide; The diastatic catalysis of ——. H. van Laer. Bull. Soc. chim. Belg., 1906, **19**, 337–361.

It is generally agreed that the indirect diastatic decomposition of hydrogen peroxide in presence of readily oxidisable reagents, such as guaiacum, or Würster's "tetra-base," is a distinct phenomenon from the direct diastatic catalysis of the peroxide which is brought about by a very large number of organic tissues. The latter phenomenon is generally attributed to the action of a specific enzyme, the catalase of Loew or reductase of Pozzi-Escot, whereas the former is regarded as a property of the peroxydases. The author has studied the catalytic properties of barley, malt, hops, yeast (including living yeast and "Dauerhefe") and the juice of potatoes. These all show great variations in their catalytic powers. For malts prepared from the same barley, the catalytic power decreases as the temperature of curing is increased. A "Dauerhefe" prepared in 1901 was still very active towards hydrogen peroxide in 1905, although its fermentative power was completely lost. Kilned malt, the seeds of hops and living and dead yeast, appear only to contain one catalytic enzyme which is insoluble (the α-catalase of Loew), whilst the juice of potatoes and some barley contain also a certain quantity of a soluble catalase (β-catalase), which, however, is partly held back by filtration. The temperature at which the catalytic enzymes are destroyed by heating in the moist condition varies according to their origin. Certain of them, *e.g.*, in malt, are very much weakened even at 30° C., others,

e.g., in "Dauerhefe" only begin to be destroyed at 40°—50° C. In all cases the catalases are characterised by a relatively low temperature of destruction, whereas the peroxydases are exceptionally resistant to high temperatures. On the other hand, both malt and "Dauerhefe," may be heated at 105° C. for several hours in the dry state without losing the whole of their catalytic power.

With concentrated solutions of hydrogen peroxide, the catalysis, rapid at first, soon slackens owing to the destruction of the catalase. With dilute solutions on the other hand, the slackening of the reaction is due to the disappearance of the peroxide, and in such cases the intensity of the reaction increases as the concentration is increased. As a result of these two opposite tendencies there is in each case an optimum concentration of hydrogen peroxide at which the catalysis is most intense, and which varies with the different preparations. When the velocity constant of the reaction reaches the maximum point, the phenomenon follows for a short time the logarithmic law of monomolecular reactions. In all cases there is a destruction of the catalase, more or less rapid according to the concentration of the peroxide, but the variable value of the catalase thereby introduced may be substituted by a mean value which may be assumed to be constant during the whole reaction. If this mean value be considered, it is observed that the diastatic catalysis of hydrogen peroxide follows the law of mass action.

—J. F. B.

Bacillus lactis aerogenes; Action of —— on dextrose and mannitol. production of 2:3-butylene-glycol and acetylmethylcarbinol. A. Harden and G. S. Walpole. Roy. Soc. Proc., 1906, **77** B., 399—405.

B. lactis aerogenes was grown anaerobically in a medium containing 1 per cent. of Witte peptone and 2 per cent. of pure dextrose in the presence of chalk. Lactic, acetic, succinic and formic acids were produced along with ethyl alcohol, carbon dioxide and hydrogen, but only about two-thirds of the carbon of the dextrose were thus accounted for. An optically-active colourless liquid, of b. pt. 181°—183° C., was extracted from the neutral liquid containing the products of fermentation. This was proved to be largely 2:3-butylene-glycol. The distillate from the culture fluid contained small quantities of acetylmethylcarbinol. Mannitol yielded similar fermentation products, the deficit of carbon being only one-half of that found for dextrose. The culture fluid was found to contain butylene-glycol and acetylmethylcarbinol. The following table (selected from the author's results) shows that *B. lactis aerogenes* produces more alcohol than *B. coli communis* and that the new products are formed at the expense of that part of the molecule which in the *B. coli* fermentation yields acetic and lactic acids:—

	Dextrose.		Mannitol.	
	B lactis aerogenes.	B coli communis.	B lactis aerogenes.	B coli communis.
Alcohol	17·1	12·85	32·5	28·1
Acetic acid	5·1	18·84	2·5	9·5
Lactic acid	5·5	31·9	8·6	18·6
Succinic acid ...	2·4	5·2	3·2	8·9
Formic acid	1·0	0·0	1·5	3·0
Carbon dioxide ..	38·0	18·09	35·5	28·4

—E. F. A.

Bacteria; Voges and Proskauer's reaction for certain ——. A. Harden. Roy. Soc. Proc., 1906, **77** B., 424—425.

CERTAIN bacteria grown in a medium containing sugar give a beautiful eosin-red fluorescent colour when potash is added to the culture fluid and the tube allowed to stand for 24 hours. The author has shown (see preceding abstract) that *B. lactis aerogenes* grown on dextrose forms acetylmethylcarbinol and 2.3-butylene-glycol, neither of which substances produces the characteristic fluorescent coloration with potash alone, but, when peptone water is also added, acetylmethylcarbinol gives the reaction after 24 hours, the coloration being produced at the open end of the tube. Diacetyl yields the coloration in a few minutes. Voges and Proskauer's reaction is thus due to the formation of acetylmethylcarbinol, oxidation of this in presence of potash and air to diacetyl, which then reacts with some constituent of the peptone water.

—E. F. A.

Yeast juice; Alcoholic ferment of ——. A. Harden and W. J. Young. Roy. Soc. Proc., 1906, **77** B., 405—420.

THE total fermentation produced by yeast juice acting on excess of dextrose is doubled by the addition of an equal volume of the boiled juice and a further increase is produced when a greater volume is added, the sugar concentration being kept constant. The constituent of the boiled and filtered juice to which this effect is due is removed when the liquid is dialysed in a parchment tube, an inactive residue being left. By filtering the juice through a Martin gelatin filter it is possible to divide the yeast juice into an inactive residue and a dialysate which, although itself inert, is capable of rendering this residue active.

A comparison of the rates of evolution of carbon dioxide from (1) a solution of dextrose in yeast juice, and (2) a similar solution to which boiled and filtered yeast juice has been added, proved that two phenomena are concerned in the production of the increased fermentation:—

(*a*) An initial rapid evolution of carbon dioxide is produced, which diminishes to a nearly constant rate, and which is usually approximately equal to that given by an equal volume of the same yeast juice and dextrose, to which no addition has been made.

(*b*) The fermentation rate diminishes more slowly, so that the fermentation continues for a longer period. The greater proportion of the total increase is due to this second phenomenon.

In the initial period the extra amount of carbon dioxide produced is directly proportional to the volume of boiled juice added. A similar well-marked initial rapid evolution of carbon dioxide was produced on the addition of soluble phosphates to yeast juice. The products of fermentation in the presence of phosphates are quite normal, the ratio of alcohol to carbon dioxide being 1·13. When the fermented liquid is boiled and filtered, almost the whole of the phosphorus present is found in the filtrate, but it is nearly all in a form which is not precipitated by ammoniacal magnesium citrate mixture. It possibly exists in combination with dextrose, probably in the form of a phosphoric ester.

The question as to whether the entire phenomenon of the fermentation of dextrose by yeast juice depends on the presence of phosphates has not yet been definitely decided.—E. F. A.

Asporogenic budding fungi occurring in and around breweries. II. H. Will. Z. ges. Brauw., 1906, **29**, 241—243.

IN a previous paper (this J., 1903, 814) it was shown that most of the asporogenic budding fungi collected in the brewery were entirely suppressed during the primary fermentation by the culture yeast. On the other hand, most of these fungi were capable of developing in clarified beer with free access of air. The author has further investigated the influence of other races of culture yeasts and of the "wild" yeasts, *S. turbidans* and *S. validus*. The power of resistance of the budding fungi was found to vary somewhat according to the species of yeast concerned in the fermentation, but in all cases the power of resistance was only slight. The behaviour of the fungi in clarified beer depends on the proportion of alcohol and on the relative access of air. Nearly all the fungi grew well in small quantities of beer, *i.e.*, where the exposed surface bore a high proportion to the total volume but only a few developed in beer kept in full bottles plugged with cotton wool, whilst only two showed any signs of growth in full bottles tightly corked. Hence it is concluded that, with good bottling, infection by these budding fungi is of little practical moment, especially since, when they do develop, they appear to have no effect on the flavour of the beer.—J. F. B.

Saccharomyces apiculatus; Morphological and physiological investigations on certain races of ——. A. Röhling. Inaug. Dissert., Erlangen; Z. ges. Brauw., 1906, **29**, 257.

THE races of apiculatus yeasts form spores on gypsum blocks which can be caused to germinate, preferably in a medium composed of horse-dung extract and dextrose. These yeasts are true saccharomycetes. The production of alcohol can be stimulated to a considerable extent by passing oxygen into the cultures; at the same time there is a vigorous multiplication of cells. The apiculatus yeasts are very sensitive to the influence of chemical agents, *e.g.*, sulphurous acid and alcohol. If apiculatus yeasts and wine yeasts are present together in a fermenting liquid, initially in about equal proportions, or if the apiculatus yeasts are present in large numbers, the course of fermentation is retarded and the product is strongly flavoured by the unpleasant bouquet developed. But if the wine yeasts predominate from the beginning, the apiculatus yeasts are suppressed, and the fermentation proceeds rapidly without the development of unpleasant bouquet and with the production of relatively large quantities of volatile acids.—J. F. B.

[*Beer Worts*] *Extract tables; The official Austrian* ——. E. Jalowetz. Allg. Z. Bierbrau. u. Malzfab., 1906, 113; Woch. f. Brau., 1906, **23**, 216.

IN Austria the extract of beer worts for excise purposes is determined by a normal saccharometer which was introduced in 1888. The instrument is based on officially sanctioned cane sugar tables constructed for a temperature of 17·5/17·5 C. These tables show sugar values which are 0·10—0·12 per cent. higher than those of Balling's tables for the same densities. On the other hand they agree well with the highly accurate, official German tables, the average difference being only 0·017 per cent. Although the Austrian tables are exact, the use of the saccharometer cannot be regarded as satisfactory, and it should be replaced by the more accurate pyknometer. The author found differences between the saccharometer values and the pyknometer values amounting to as much as 0·22 per cent. of extract in worts ranging from 8·9 to 12·2 per cent. He also draws attention to the anomaly of using Balling's tables in the determination of extract in malts and the normal tables in the determination of extract in brewery worts.—J. F. B.

Fluorine in alimentary products [*and wine, beer, &c.*]; *Optical method for the detection of* ——. J. Ville and E. Derrien. XXIII., page 499.

ENGLISH PATENTS.

Kilns for drying hops or the like; Impts. in ——. H. W. Joyce, Hereford. Eng. Pat. 9264, May 2, 1905.

AN air-heating shaft, relatively narrow with respect to the area of the kiln, underneath which it is placed, has a furnace, preferably of the kind described in Eng. Pat. 10,988 of 1902, situated near the bottom. The products of combustion from the furnace pass through a zig-zag or spiral flue placed within the shaft, to an outlet on the outside of the kiln. Cold air enters the bottom of the shaft, becomes heated by contact with the flue, and rises through the floor of the kiln, even distribution being attained by placing a deflecting plate over the top of the shaft. A second current of air, heated by passing through the hollow fire-bars, passes through a vertical pipe within the shaft, and is delivered above the materials in the kiln. The furnace may also heat a boiler having circulating pipes leading to a coil in the upper part of the shaft, the radiation from the coil assisting the heating of the air.—W. H. C.

Non-intoxicating drinks; Compounds for making ——. J. H. Brodrick, Dudley, Worcester. Eng. Pat. 15,079, July 21, 1905.

THE process is an improvement on Eng. Pat. 25,149 of 1898 (this J., 1899, 1147). One bushel of malt is steeped in 9 galls. of water at a temperature of 180° F. and allowed to cool to about 150° F. The malt is then dried, its starch having been thus converted into glucose. The hops used in making the beverage are also boiled and dried. The malt and hops thus treated are substituted for the roasted malt and hops described in the previous patent and with the other ingredients are compressed into tablets which are used for making the beverage.—W. P. S.

UNITED STATES PATENT.

Drying apparatus for malt. E. Ellermann, Berlin, Germany. U.S. Pat. 817,698, April 10, 1906.

THE apparatus comprises a hollow rotatable shaft on which is fixed a worm conveyor surrounded by a perforated cylinder concentric with the shaft. A number of concentric heating coils are arranged without the cylinder and the whole apparatus is enclosed in an outer casing. The malt or other material to be dried is fed to the inner cylinder at one end, is carried along by the conveyor and returned again through the annular space between the coils and the outer casing.—W. H. C.

FRENCH PATENT.

Wines and fermented liquids; Sulphitation of —— by known quantities of sulphurous acid. J. Laborde. Fr. Pat. 360,838, Dec. 11, 1905.

ACCORDING to this invention a known quantity of wine in a cask is treated with a known quantity of liquid sulphur dioxide, which is contained in a cartridge or metallic bottle. The cartridge is inserted in a perforated cylindrical casing which carries a punch attached to a piston at the bottom. The case containing the cartridge is dropped with some force into the cask of wine. The shock of the piston striking the bottom forces the punch through the lead cap of the cartridge; the sulphur dioxide escapes in the gaseous form and is distributed through the perforations in the casing.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A.)—FOODS.

Cocoa; Determination of fat in ——. Tschaplowitz. XXIII., page 500.

Fluorine in alimentary products [*and wine, beer, &c.*]; *Optical method for the detection of* ——. J. Ville and E. Derrien. XXIII., page 499.

ENGLISH PATENTS.

Bread making; Yeast stimulant or nutrient for use in ——. L. Fink, Berlin. Eng. Pat. 27,081, Dec. 28, 1905.

A YEAST stimulant is made of a mixture of 20—25 parts of calcium citrate, 60—70 parts of calcium hydrogen phosphate and 5—20 parts of potassium hydrogen tartrate; 10—15 parts of the above mixture are mixed with 35—40 parts of sugar. For bread-making, one part of yeast is mixed with water at a temperature of 50° C., and 1·5 parts of the above mixture are added. After a short time the liquid is mixed with the usual proportions of flour and water. Fermentation is stated to be complete in 10—20 minutes.—J. F. B.

Alimentary product from Iceland lichen [*Cetraria islandica*]; *Process of producing an* ——. B. Hansteen, Aas, Norway. Eng. Pat. 5195, March 3, 1906. Under Int. Conv., March 7, 1905.

THE lichen is first washed and cleaned by means of hot water, and then boiled for at least 20 minutes with a 15 per cent. solution of alkali carbonates, the mixture being stirred continuously. After the alkali solution has been filtered off, the material is repeatedly boiled and washed with water until the washings are colourless, salt is added and the product pressed and sterilised.

—W. P. S.

French Patents.

Cereals; Treatment of [Bleaching] ——. Nordyke and Marmon Co. Fr. Pat. 359,771, Feb. 1, 1905.

The cereals are subjected to the action of the gas resulting from the passage of ammonia gas over metallic oxides, such as copper oxide.—W. P. S.

Flour [inferior]; Process of rendering —— more suitable for baking purposes. R. F. C. Merelle. Fr. Pat. 360,142, Feb. 14, 1905.—W. P. S.

Flour which has deteriorated on account of fermentation, &c., may be rendered fit for bread-making by heating it to a temperature of from 60° to 80° C. in a closed vessel, so that there shall be no loss of moisture. This treatment is stated to alter the composition of the gluten of the flour, the gliadin being converted into glutenin.—W.P.S.

Blood and fluid extracts of animal tissues; Process for desiccating . J. R. Hatmaker. Fr. Pat. 360,800, Nov. 17, 1905. Under Int. Conv., Nov. 18, 1904.

See Eng. Pat. 25,077 of 1904; this J., 1905, 1319.—T.F.B.

Fish extract free from oil; Manufacture of —— . P. Hagen. Fr. Pat. 359,952, Nov. 30, 1905.

Fish, preferably herrings, are cleaned, washed and ground. The mass is then boiled with water in the proportion of 1:100 and the extract strained to remove solid matters. The turbid solution is now heated with the addition of beef or mutton fat, 5 per cent. of the latter being added for each 1 per cent. of fish oil in the solution. On cooling, the animal fat separates out, carrying with it all the fish oil. After removing the fatty layer, the aqueous extract is evaporated to a paste in the usual manner.—W. P. S.

Milk and milk products, Process for the desiccation of ——. G. A. Kammermann. Fr. Pat. 360,358, Dec. 12, 1905.

The milk, or a mixture of the latter with sugar, coffee, cocoa and the like, is partially evaporated in open vessels or under reduced pressure at a temperature below 100° C. The condensed product is then dried on rotating cylinders heated to a temperature below 100° C., and is finally powdered.—W. P. S.

German Patent.

Product for baking purposes consisting of albumin and casein; Process for the preparation of a ——. Gebr. Schredelseker. Ger. Pat. 166,849, Jan. 20, 1905.

The process claimed is an improvement on that described in Ger. Pat. 103,156, and consists in adding liquid yolk of egg to skimmed or separated milk, either shortly before the addition of rennet, or after coagulation of the casein. It is stated that the baking and other properties of the product are improved.—A. S.

(*B.*)—SANITATION; WATER PURIFICATION.

English Patents.

Smoke and fumes from refuse-destroying furnaces and the like; Consumption of the ——. H. Fairbrother, London. From the Decarie Manufacturing Co., S. Minneapolis, U.S.A. Eng. Pat., 18,915, Sept. 19, 1905.

The smoke from the destructor furnace passes through openings into a gas-consuming chamber, and thence down a flue, provided with a water-tank at its bottom, into a secondary furnace. The latter consists of two separate fires, the upper one having a down-draught. After passing this furnace the fumes are led upwards and over a partition, then downwards over the surface of water contained in tanks, a stream of water falling into the first tank forming a sheet through which the fumes must pass. The washed gases finally enter the chimney-shaft.—W. P. S.

Sewage; Apparatus for the automatic destruction or bacterial treatment of ——, and for the purification of effluent or residual liquids. V. Bordigoni, Paris. Eng. Pat. 24,332, Nov. 24, 1905.

The apparatus consists of a tank divided into four chambers; two of the latter are closed and the other two open to the air. The sewage is delivered into the first closed chamber, which is divided into three compartments. Two of these are comparatively small, and serve for the intermittent reception of the sewage, whilst the third compartment extends under the other two, and is separated from the same by perforated partitions. After passing through these compartments the sewage passes into the bottom of the second chamber, which is fitted with baffle-plates, and thence into the first open chamber, entering at the top. This chamber is divided into two compartments separated by a partition perforated at the bottom; the second of these compartments is partly filled with blocks of limestone. The sewage finally passes into the last chamber, which contains a series of small tanks placed one above the other, each tank being filled with oxidising materials and divided into parallel compartments. A tipping bucket discharges the sewage alternately into the compartments. After traversing these layers the liquid flows into a receptacle, where it is treated with a mixture of permanganate, calcium chloride, and bisulphite, before being discharged. (See also Eng. Pat. 11,900 of 1904; this J., 1904, 833.)

—W. P. S.

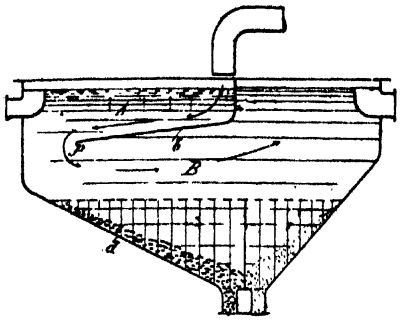
United States Patents.

Sewage; Apparatus for treating . M. van B. Smith, New York. U.S. Pat. 817,996, April 17, 1906.

An endless band, composed of separate sheets of wire-cloth, the mesh of the outer layer being so fine as to prevent water under normal conditions passing through it, is mounted in two horizontal "runs." A number of rollers are placed in contact with the under surface of the upper part of the band so as to draw the water through the band and discharge the same. Means are provided for cleansing the band at its lower part from the solid portions of the sewage, a jet of water under high pressure serving this purpose.—W. P. S.

Distilling apparatus [for water]. L. Kleitz, Chicago, Ill. Assignor to E. C. Wagner, La Fayette, Ind. U.S. Pat. 818,831, April 24, 1906.

The claim is for a boiler or still, the vapour-pipe of which is connected by bends and a sliding joint to the upper end of a vertical condenser-tube. The latter is surrounded by a condenser-casing through which the cooling water flows and from which the still is fed by a pipe having a coupling joint so that the still may be disconnected when required. The still is supported by a separable bracket attached to the outer side of the condenser-casing.



—W. H. C.

German Patents.

Water; Apparatus for the chemical, mechanical and biological purification of ——. F. W. Dünkelberg. Ger. Pat. 165,414, Aug. 9, 1904.

The apparatus consists essentially of two concentric cylinders with a filtering layer between. The outer cylinder has at the top a flange or rim projecting inwardly and forming a distributing channel for the water. To the inner surface of this outer cylinder is affixed a series of metal tubes having fine perforations and filled with superposed short drain pipes of earthenware or the like, the uppermost pipes projecting into the distributing channel. The water deposits its coarser suspended particles in the distributing channel and then flows through earthenware pipes and perforations in the metal tubes to the filtering layer, and, finally, through narrow slits into the inner collecting cylinder. The clayey impurities and dissolved salts are stated to be retained to a large extent by the earthenware pipes, whilst organic impurities are destroyed by bacterial action during the passage through the filtering layer.—A. S.

Settling-tank especially for drain-water. P. Heyer. Ger. Pat. 165,406, Dec. 11, 1904.

THE tank is provided with a partition, *b*, dividing it into two compartments, A and B, in which the water flows in opposite directions, as shown by the arrows. The wall, *d*, of the tank, opposite the turning point, *p*, of the current of water, has only a slight inclination and the cross-section of the tank at this part is increased, in order to retard the flow of the water. In this way the specifically lighter impurities rise to the surface in the compartment, A, and are drawn off, whilst the heavier particles collect on the bottom of the tank.—A. S.

(C.)—DISINFECTANTS.

Sodium phenylpropiolate; Bactericidal properties of ——. Y. Kozai. Bull. Imp. Centr. Agric. Experim. Stn., Japan, 1905, **1**, 69—72.

A 1 PER CENT. solution of sodium phenylpropiolate has a strong bactericidal effect in three hours, except in the case of sporogenic bacteria, which will continue to develop after exposure to a 3 per cent. solution for 24 hours (5 per cent. in the case of *Bac. subtilis*). Very little effect is produced by more dilute solutions, such as 0·15 per cent. The action is due to the phenyl group and triple bond, and is intensified by substituting an aldehyde group for the carboxyl group, the development of various bacteria being retarded by a 0·04 per cent. solution of phenylpropiolic aldehyde.—C. S.

ENGLISH PATENT.

Size from resin and other materials [for paper-making] and bye-products [disinfectant]; Apparatus for the manufacture of ——. A. Bigland. Eng. Pat. 14,402, July 12, 1905. See next page.

UNITED STATES PATENT.

Disinfecting compound. J. W. England, Assignor to Smith, Kline and French Co., Philadelphia, Pa. U.S. Pat. 817,166, April 10, 1906.

A COMBINATION of mercuric iodide and lithium iodide is claimed. The compound is soluble in water, alcohol and ether, without decomposition.—W. P. S.

FRENCH PATENTS.

Organic substances; Oxidation of —— by partial combustion. J. Walter. Fr. Pat. 360,785, Oct. 11, 1905. Under Int. Conv., Oct. 27, 1904.

FOR the partial combustion of gaseous organic substances, chiefly for the manufacture of formaldehyde, the gases or vapours are intimately mixed with air and steam before being introduced into the heating chamber. Means are provided for maintaining constant temperatures in the heating chamber, the temperature depending on the composition and velocity of the current of gases, the quantity of steam used and the sectional area of the chamber. The steam acts as a diluent, preventing explosions, absorbing the excess of heat of combustion and facilitating condensation of the product. In certain cases suitable catalytic agents may be used. The heating chamber may consist of a bundle of tubes heated externally.—J. F. B.

Soap, ointment or paste for disinfecting purposes; Process of making —— [Peat tar]. J. Kessler and Co., Fr. Pat. 360,174, Dec. 7, 1905.

TAR, obtained by the distillation of peat, is added to the soap, ointment, &c. —W. P. S.

XIX.—PAPER, PASTEBOARD, Etc.

(*Continued from page* 442.)

Sulphite wood pulp waste liquors; Contribution to the chemistry of ——. H. Krause. Chem. Ind., 1906, **29**, 217—227.

BY the Mitscherlich process the wood is boiled for a long time at a temperature of 116°—120° C. by means of closed steam coils, whereas in the Ritter-Kellner process it is boiled for a much shorter time at a temperature of 130°—135° C. by means of direct steam. The principal organic constituent of the waste lyes is the calcium salt of lignin-sulphonic acid, but, corresponding to the higher temperature of digestion, the Ritter-Kellner liquor has a darker colour and contains more furfural and generally more sugars than the Mitscherlich liquor. Fehling's solution is not suitable for the detection of sugars in the liquors, since the lignin derivatives exert a reducing action even in the cold. Nylander's bismuth solution, however, is not reduced by the lignin bodies, and can be employed for the detection of the sugars. The separation of the sugars is best effected by evaporating the liquor in presence of barium carbonate to a pasty consistency, mixing the product with sand, and extracting the sugar by exhaustion three to six times in succession with hot 90 per cent. alcohol. The author's observations showed that in both processes of digestion the liquors from wood boiled in the autumn contained about double as much sugar as those obtained in the spring. The waste liquors contain free furfural, pentosans and pentoses; the lignin constituents of the liquors yield no furfural on distillation with hydrochloric acid. In addition to the pentosans and pentoses, the liquors contain hexosans and hexoses. Amongst the sugars present, the author has identified xylose, mannose, galactose, levulose and traces of dextrose. The following table shows the results of analyses made of two liquors obtained in the autumn by the two processes:—

	Mitscherlich.	Ritter-Kellner.
	per cent.	per cent.
Furfural	0·01	0·02
Pentosans	0·40	0·29
Hexosans	0·21	0·49
Total sugars	1·48	1·47
Pentoses	0·47	0·41
Mannose	0·48	0·48
Levulose	0·28	0·25
Galactose	0·01	0·01
Dextrose	—	trace

The author has also investigated to a certain extent the lignin derivatives of the liquor. On the addition of bleaching powder to the liquor acidified with hydrochloric acid, a chloro derivative was obtained, which after purification by alcohol and ether, showed a composition corresponding with the formula, $C_{26}H_{29}ClSO_{12}$. This and other derivatives of lignin-sulphonic acid have the peculiarity of being soluble in alcohol only when acidified, whereas the presence of acid decreases their solubility in water. The author found that on boiling the liquors with dilute caustic potash, the greater portion of the combined sulphur was split off, without apparently any profound decomposition.—J. F. B.

ENGLISH PATENTS.

Paper; Coating and drying ——. S. Stephan, London. From P. V. Rolier, Paris. Eng. Pat. 7766, April 12, 1905.

THE paper is wound off the reel and is coated on a drum,

the axle of which is hollow and non-rotatory, and communicates with a vacuum chamber on the one hand, and with a perforated part of the wall of the coating-drum on the other hand. The coated paper then passes to a drying apparatus consisting of a stack of guide rolls between which hot air is circulated. The drying arrangement is so constructed that the rolls touch the paper on the uncoated side only. After passing round the drying apparatus several times, the web of paper reaches the centre of the stack sufficiently dry to be reversed by a reversing guide-roll, and it then passes with its uncoated side uppermost to a second coating machine, and thence to a second drying-stack, after which it is stretched and reeled in the usual way.—J. F. B.

Paper; Manufacture of ——. R. Binns, South Windham, Conn., U.S.A. Eng. Pat. 12,413, June 15, 1905. Under Int. Conv., June 18, 1904.

SEE U.S. Pat. 785,704 of 1905; this J., 1905, 511.—T.F.B.

Size from resin and other materials [for paper-making] and bye-products [disinfectant]; Apparatus for the manufacture of ——. A. Bigland, Liverpool. Eng. Pat. 14,402, July 12, 1905.

THE resin, or a mixture of resin, fats and oils, is mixed with a suitable quantity of alkali or alkali carbonate and boiled in a closed vessel. The latter is provided with stirrers and a tube leading from the top, through which the gases (chiefly carbon dioxide) and volatile products generated are drawn off by the action of a vacuum pump. The gases, &c., are passed through condensers, and a chamber where the liquid portion is separated. The gases are then pumped into the bottom of a vessel containing water, by which a quantity of volatile oils is separated. Means are provided for collecting the gases for further use. As soon as the saponification is finished, or nearly so, the mass is withdrawn from the bottom of the vessel and pumped into a second closed vessel where the boiling is continued until no more gases and volatile matters are evolved, the upper part of the vessel being provided with a pipe leading to the condenser, &c., for the collection of these products. The liquid portion separated from the gases may be used for disinfecting or other purposes.—W. P. S.

UNITED STATES PATENTS.

Wood; Process of treating —— for the production of paper pulp, terpenes and resinous substances. G. P. Craighill and G. A. Kerr, Assignors to N. C. Manson, jun., Lynchburg, Va. U.S. Pat. 817,960, April 17, 1906.

WOOD is "chemically treated" at a moderate temperature to fix the volatile acids and oils, and to expel the terpenes; the solution containing the resinous substances, acids, &c., is then withdrawn and worked up, and the residue is treated first with caustic soda, then with sodium carbonate, and is finally bleached with sodium hypochlorite to form paper pulp.—T. F. B.

Paper pulp; Manufacture of ——. M. le Normant des Varannes and A. R. de Vains, St. Vincent de Blanzat, France. U.S. Pat. 818,206, April 17, 1906.

SEE Eng. Pat. 505 of 1905; this J., 1906, 195.—T. F. B.

GERMAN PATENTS.

Vegetable materials of all kinds, e.g., straw, wood, &c.; Process for working up —— for paper-making. Worschen-Weissenfelser Braunkohlen A.-G. Ger. Pat. 166,411, Feb. 18, 1904.

CLAIM is made for the application to the purpose mentioned in the title of the "sodium or potassium compounds of creosote" (Kreosotnatron oder Kali), or similar substances obtained in the treatment or distillation of tars of different origin with caustic soda or caustic potash solution. It is claimed that these substances are superior to the reagents usually employed, as they dissolve the encrusting substances of the vegetable materials without attacking the cellulose; and also that owing to the presence of phenols, the ill odour produced by organic sulphur compounds is suppressed. The reagents can be employed either directly, or preferably after dilution with water and separation of the so-called "neutral creosotes," which interfere with the subsequent bleaching process.—A. S.

Fibrous substances [textiles, leather, paper, &c.]; Process for waterproofing ——. Chem. Fabr. Flörsheim, Dr. H. Noerdlinger. Ger. Pat. 166,350, May 12, 1904. V., page 475.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 443)

Morphine. VII. Conversion of thebaine into codeinone and codeine. L. Knorr and H. Hörlein. Ber., 1906, **39**, 1409—1414.

CODEINONE, which is obtained by the oxidation of codeine by chromic acid or permanganate, is related to thebaine in the same way as morphine is to codeine, thebaine being the methylic ether of the enolic form of codeinone. One of the methoxyl groups of thebaine is very easily hydrolysed with the production of codeinone as the ketonic form. The codeinone can then be converted into codeine by reduction. This hydrolysis takes place when thebaine is boiled for a short time with dilute sulphuric acid or even on standing in the cold. Codeinone is the primary product of the hydrolysis, the conversion being analogous to the hydrolysis of alkyl-vinyl ethers of the aliphatic series, which are split up into alcohols and aldehydes or ketones. The main products of the acid hydrolysis of thebaine, *viz.*, thebenine and morphothebaine, are secondary products.
—J. F. B.

Hydroxycodeine; The splitting of —— by complete methylation. L. Knorr and W. Schneider. Ber., 1906, **39**, 1414—1420.

CODEINE yields two oxidation products, codeinone (see preceding abstract) and hydroxycodeine. Whilst the former shows a close relationship to thebaine, the latter presents a complete analogy to codeine in its reactions. Like codeine, hydroxycodeine is very stable towards boiling acetic anhydride, with which it yields a diacetyl derivative. On complete methylation by Hofmann's method it behaves like codeine. The methyliodide of hydroxycodeine, on boiling with caustic soda solution, yields a methine base, *hydroxymethylmorphimethine*, which is split up on boiling with acetic anhydride. The nitrogenous product of the decomposition is *ethanol-dimethylamine*, whilst the non-nitrogenous product is *methyldiacetyl-trihydroxyphenanthrene*. The trihydroxyphenanthrene, from which this is derived, bears the same relation to morphol as hydroxycodeine does to codeine, *i.e.*, one of its hydroxyls is the same as was attached during the oxidation of codeine to hydroxycodeine. Codeinone, when split up by boiling with acetic anhydride, yields 3-methoxy-4.6-diacetyldihydroxyphenanthrene which contains, in addition to the two hydroxyls of morphol, the alcoholic hydroxyl of codeine. The identification of the trihydroxyphenanthrene from hydroxycodeine will lead to the orientation of the hydroxyl group of codeine which is still undetermined.—J. F. B.

Essential oils; Influence of the season of distilling and hybridation on the composition of some ——. A. Bircken-stock. Monit. Scient., 1906, **20**, 352—356.

THE differences between French and Algerian oil of rue have been attributed to different botanical origin of the plants; such, however, is not the case: the differences arise entirely from the different seasons in which the oils are distilled, French rue being distilled in autumn and Algerian in spring and early summer. Algerian rue distilled in spring gave an oil of sp. gr. 0·8446; optical rotation, −4°; freezing point, −11°C.; whilst when it was distilled in autumn the oil had a sp. gr. of 0·837; optical rotation, +0° 40′; and freezing point, +9·7° C., thus

resembling the French oil fairly closely. French oil of rosemary is generally only considered pure when the head fraction (10 per cent.) is dextro-rotatory. It is shown, however, that when rosemary is distilled at the beginning of the season (April—June), the first 10 per cent. of the oil distilling over is always lævo-rotatory; it is considered highly probable that the oils contain the same amount of pinene at whatever season they are distilled: in spring it is *l*-pinene which is more abundant in the oil, whilst in autumn *d*-pinene preponderates. Spanish rosemary distilled in spring gave a dextro-rotatory oil, the rotatory power of which was considerably greater than that of the oil produced in autumn: the Spanish oil was characterised by its containing more terpenes than the French oil: the first fractions (20 per cent.) consisted almost entirely of pinene. Some specimens of lavender oil, obtained from the French and Italian Alps, showed a sp. gr. of 0·878 to 0·8829, optical rotation, $-8°$ to $-9°$; they contained about 50 per cent. of *l*-linalool and 20—30 per cent. of linalyl acetate. A series of hybrid plants was traced, linking the aspic and lavender, and essential oils were obtained from these, a series being obtained passing from the true oil of aspic (sp. gr., 0·92 and $\alpha_D = +10°$) to the true oil of lavender (sp. gr., 0·89, $\alpha_D = 7° 30'$; esters, 45 per cent.); the characteristics of these oils are given in a series of tables, showing the gradual increase of esters from 2 to 3 per cent. in the oils of aspic to 40—45 per cent. in the pure lavender oils. It is pointed out that pure oils of aspic may show an optical rotation of $-1° 10'$, the first 10 per cent. of the distillate being dextro-rotatory.—T. F. B.

Otto of rose. London Essence Co.'s Report, March, 1906, 9.

An otto of rose, distilled in a special manner in Bulgaria, was found to contain a large amount of phenylethyl alcohol. Its characteristics were: Sp. gr. $(30°/15°)$, 0·884; optical rotation, $-2°$; congealing point, 18·5° C.; m. pt., 19° C.; content of stearoptene (m. pt. 33·5° C.), 9 per cent.; ester value, 81·6; alcohol value, 236·4; iodine value, 157·2. The otto appears in no way inferior to those free from phenylethyl alcohol.—T. F. B.

Linaloe oil. London Essence Co.'s Report, March, 1906, 7.

Several samples of linaloë oil of authentic origin were found to be dextro-rotatory. Two typical samples gave the following figures:—Sp. gr., 0·8825, 0·8775; optical rotation, $+4° 30'$, $+3° 10'$; acid value, 0·9, 1·4; ester value, 11·5, 9·8; refractive index, 1·4641, 1·4608. The determination of linalool in one of the samples by acetylation gave a result equivalent to 68·5 per cent.—T. F. B.

Cardamine oil. Feist. Apoth.-Zeit., 1905, 832. London Essence Co.'s Report.

The essential oil distilled from *Cardamine amara* consists almost entirely of one of the sulphur compounds characteristic of this type of plant. It yields a crystalline thiocyanate of m. pt. 134°—135° C. The sulphur content of the oil agrees with the formula, $C_5H_{12}N_2S$, suggesting that the compound is a secondary butyl thiocyanate. The fresh herb contains about 0·35 per cent. of oil.
—T. F. B.

Copaiba oil; African ——. Kline and Fenwick. Amer. J. Pharm.; London Essence Co.'s Report, March, 1906, 5.

The specific gravity of African copaiba varies between 0·991 and 0·999, and the oil content between 43 and 45 per cent. The sp. gr. of the oil is 0·928, and the optical rotation $+5° 45'$, a figure considerably lower than that usually given.—T. F. B.

Phenacetin; Adulteration of —— with parachloro-acetanilide. C. Mannich. Ber. Pharm., 1906, 57.

A specimen of phenacetin, having the abnormal m. pt. 119°—120° C. and containing 5·89 per cent. of chlorine, was found to be adulterated with 18 per cent. of parachloro-acetanilide. The impurity was isolated by treatment with ether, and recrystallising the extracted matter several times from boiling water. The product thus obtained, m. pt. 175°—177° C., had the formula, C_8H_8ClNO, and gave a bluish-violet colour when boiled with strong sulphuric acid.—J. O. B.

Rare earths; History of the discovery of ——. C. R. Boehm. Chem. Ind., 1906, **29**, 172—176; 189—197.

The author gives a detailed bibliography of the literature relating to the discovery of rare earths from the detection of an unknown earth metal in scheelite (Schwerstein) from Bastnäs by Cronstedt in 1751 and its isolation, and naming as cerium by Berzelius and Hisinger in 1804. The bibliography is divided into the following sections:—History of cerite elements; history of ytterite elements; history of thorium; history of zirconium.—A. S.

Ethyl glyoxylate; Characteristic reaction of ——. *Action of ammonia on the ether and its derivatives.* L. J. Simon and G. Chavanne. XXIII., page 499.

Methyl alcohol in formaldehyde solutions; Determination of ——. O. Blank and H. Finkenbeiner. XXIII., page 500.

Acetone; Determination of ——. A. Jolles. XXIII., page 500.

Butyl chloride; Exemption from duty of —— in Holland. Bd. of Trade J., May 10, 1905.

A Dutch Royal Decree, dated April 9, 1906, exempts from import duty, subject to certain conditions, butyl chloride for use in the manufacture of artificial musk. Application for exemption must be made to the Minister of Finance by the manufacturer desiring to use the substance in his factory. [T.R.]

English Patents.

Hypnotic compounds. E. C. Clemmensen and A. H. C. Heitmann, Detroit, U.S.A. Eng. Pat. 7840, April 12, 1905.

See U.S. Pat. 814,693 of 1906; this J., 1906, 392.—T.F.B.

Oxalates and oxalic acid; Process of making ——. F. A. Feldkamp, South Orange, U.S.A. Eng. Pat. 22,225, Oct. 31, 1905.

See U.S. Pat. 802,980 of 1905; this J., 1905, 1254.—T.F.B.

Borneol esters and isoborneol esters; Production of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 6606, March 19, 1906.

Pinene hydrochloride is stated to be converted into a mixture of borneol ester and isoborneol ester, containing no chlorine compounds, by boiling, under a reflux condenser, with a zinc salt of an organic acid in presence of an organic acid. The following proportions may be used:—100 parts of pinene hydrochloride, 55 parts of zinc formate and 300 parts of 90 per cent. acetic acid. After boiling for three or four hours, the mixture is allowed to stand for some time and the acetic acid is distilled off *in vacuo*. The residue is washed with water and distilled, the mixture of esters distilling over between 102° and 105° C. (12 mm.).
—T. F. B.

French Patents.

Ethyl alcohol from acetylene; Preparation of ——. M. J. A. Jouas, M. L. Desmonts, L. P. I. Deglatigny, and L. A. Dubosc. Fr. Pat. 360,180, Feb. 15, 1905.

Acetylene gas is passed into a solution of a normal mercuric salt, causing the precipitation of mercury acetylide. On boiling this liquid, the acetylide decomposes, liberating aldehyde and re-forming the mercuric salt. The aldehyde can be reduced to alcohol by sodium amalgam.—F. Shdn.

Acetic acid from acetylene; Preparation of ——. M. J. A. Jouas, M. L. Desmonts, L. P. I. Deglatigny, and L. A. Dubosc. Fr. Pat. 360,249, Feb. 17, 1905.

ALDEHYDE, prepared by the method described in the previous patent (Fr. Pat. 360,180 of 1905), is oxidised directly, or by catalytic agents, to acetic acid.—F. SHDN

FRENCH PATENTS.

α-β-Substituted glycidic esters and ketones; Synthetical preparation of ——. G. Darzens. Fr. Pat. 360,513, Feb. 25, 1905.

α-β-SUBSTITUTED glycidic esters are produced by the condensation of aldehydes or ketones with an ester of an acid containing a halogen or acetyl group in the α-position, under the influence of an alkali ethylate or of sodium amide. The reaction takes place according to the equation:

$$R.CO.R' + R''CHX.COOC_2H_5 = R.CR'(\diagup O \diagdown)CR''.COOC_2H_5 + HX.$$

The α-β-glycidic esters so produced are saponified and the free acids are said to be decomposed by heating with the production of ketones of the type $R.R'CH.C:O.CH_2.R''$ and evolution of carbon dioxide. Certain of these ketones are utilisable for the production of perfumes.—J. F. B.

Chloroform; Process for preserving ——, *from air and light and eventually indicating its decomposition.* J. P. Breteau. Second Addition, dated Nov. 18, 1905, to Fr. Pat. 353,858, June 30, 1905 (this J., 1905, 1083 and 1254).

THE "indicator" may be interposed between the chloroform and the stopper of the vessel containing it, or fixed to the stopper or even itself form the stopper. Cinnamic acid and mesite-mono-methyl ether are added to the list of preservative agents.—W. P. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 444.)

Development with diaminophenol in acid solution and in alkaline solution in presence of alkalis or their substitutes. A. and L. Lumière and A. Seyewetz. Bull. Soc. Franç. Phot., 1906, **22**, 76. Phot. J., 1906, **46**, 108.

AN aqueous solution of amidol (diaminophenol dihydrochloride) acquires considerable developing powers when sufficient sulphite is added to saturate the hydrochloric acid, notwithstanding the presence of free sulphur dioxide. The reducing power of the developer is much increased by adding just sufficient sulphite to completely convert the sulphur dioxide into bisulphite: the increase is still greater if sufficient alkali hydroxide or carbonate is added to form the normal sulphite. The addition of further quantities of sulphite, even to saturation, does not produce an alkaline developer; when more than 6 parts of sulphite are used to one of amidol, the reducing power does not increase; in fact, above 20 parts to one, it decreases. The sulphite in the normal developer may be in great part replaced by alkali, without diminution of the reducing power. The reducing power of the "normal" developer may be considerably increased by adding alkalis or their substitutes, particularly ammonia, lithium carbonate and acetone. The acidity of amidol developers appears to be in no way connected with their reducing powers.—T. F. B.

Developers; Action of alkalis in organic ——. A. and L. Lumière and A. Seyewetz. Bull. Soc. Franç. Phot., 1906, **22**, 32. Phot. J., 1906, **46**, 109.

THE three caustic alkalis (lithia, soda and potash) may be used, in equimolecular weights, with the same reducing agent, to produce developers having the same reducing power, but alkali carbonates and other substitutes for alkalis (*e.g.*, acetone or trioxymethylene) must be used in much greater quantity (see Sheppard, this J., 1906, 444). The same reducing effect can be obtained with equimolecular weights of the various reducing agents, but only by adding variable quantities of an alkali. The following list gives the reducing agents arranged according to the quantity of alkali hydroxide required, metoquinone taking the least:—Metoquinone, metol-quinol, *p*-aminophenol, *p*-phenylenediamine, hydramine, pyrogallol, quinol, catechol, metol, eikonogen, edinol, adurol, glycin. With alkali carbonates, on the other hand, the order is somewhat different, being as follows:—Metoquinone, metol-quinol, metol, pyrogallol, eikonogen, adurol, edinol, quinol, catechol, glycin. Incomplete solution was obtained with *p*-aminophenol and hydramine, and *p*-phenylenediamine is not included in the list, since it most probably combines with the hydrobromic acid liberated before the latter decomposes the sodium carbonate, and the hydrobromide thus formed is not decomposed by alkali carbonate, but only by alkali hydroxide.—T. F. B.

Gelatin; The "tanning" of —— *during development, especially with "pyro" [pyrogallol].* A. and L. Lumière. Brit. J. Phot., 1906, **53**, 285—286.

IT is generally considered that pyrogallol developers alone possess the property of rendering gelatin insoluble during development. When gelatin or a negative developed by another developer is immersed in a pyrogallol developer, no "tanning" occurs after an hour, but after several days, with access of air, both become insoluble. Aqueous solutions of pyrogallol and other developers have no tanning action on gelatin after a month's immersion, even with access of air, but solutions containing alkali carbonate and sulphite, when air is present, all produce more or less tanning: in absence of air no tanning occurs. Quinone is the cause of this tanning action, a 0·5 per cent. solution rendering gelatin insoluble, even with exclusion of air. It thus appears to be the property of the pyrogallol developer of rapidly absorbing oxygen, which favours the tanning of gelatin. It is probable that the oxidation products formed during development with other reducing agents than pyrogallol are decomposed by the sulphite present, and hence cause no tanning under the ordinary conditions.—T. F. B.

ENGLISH PATENT.

Gelatin emulsion papers; Manufacture of sensitised ——. L. Robiesek, Vienna. Eng. Pat. 7693, April 11, 1905.

SEE Fr. Pat. 353,349 of 1905; this J., 1905, 1031.—T. F. B.

FRENCH PATENT.

Photographs in colours; Production of —— *and polychrome screens for use therein.* C. L. A. Brasseur. First Addition, dated Oct. 24, 1905, to Fr. Pat. 349,742, Dec. 30, 1904.

A SHEET of glass, to which a layer of sodium silicate has been applied, is coated with a very thin film of bichromated gelatin, dried, and coated with a layer of collodion containing a solvent common to the nitrocellulose and to the gelatin (*e.g.*, glacial acetic acid), in such a quantity as to firmly cement the two layers together. The whole is now exposed to light, washed with water, and a sensitive collodion layer, containing the necessary colouring matter, is applied to it. The plate is then exposed beneath a negative, fixed (or developed and fixed), and again coated with further sensitive collodion layers and treated as before to supply the other colours. (See Eng. Pat. 21,210 of 1904; this J., 1905, 1190.)—T. F. B.

GERMAN PATENT.

Dyestuffs of the cyanine series; Process of preparing sensitising ——. Meister, Lucius und Brüning. Ger. Pat. 167,770, May 26, 1903. IV., page 471.

(*Continued from page* 445.)

Bursting of M.L.E. Rifles; Report on the —— to the Minister of Defence, Victoria. By C. W. Hake and T. R. Lyle.

A NUMBER of rifles having burst whilst being fired, the authors were requested by the Minister of Defence to enquire into the circumstances, and if possible to ascertain the cause of the accidents. Previous to this, the New South Wales Military Board and a Victoria Military Board had held enquiries, and although, on the whole, their reports were of a negative character, a certain amount of suspicion had been thrown on the design of the M.L.E. rifle. The accidents had been ascribed by them to the presence of flaws in the cartridge cases, on the strength of the base of which, they supposed, depended the direction which the force of explosion would actually take. It is shown, however, that the so-called "flaws," were effects which might be produced in any cartridge case on firing, especially with excessive pressure.

In the reports of the evidence taken by these Boards, it is shown that one of the rifles still contained a bullet, although a bull's eye had been registered on the target at which aim had been taken. Examination showed that this extra bullet in some instances had still remained in the cartridge case, that it had never engaged the rifling of the gun, and that its base had been deformed by fusion. Moreover, there were distinct marks where the bullet had been stabbed. These facts suggested to the authors the possibility of there having been two bullets in the original cartridge. Calculations showed that such an occurrence would result in excessive pressure within the explosion chamber, and a burst might be expected, although the foremost bullet might be ejected.

In order to test the "two-bullet" theory, cartridges were made with an additional bullet inside the brass case, both upright and reversed. The latter, on firing, burst the rifle, whilst the former severely strained the bolt action. In the burst rifle, the effects were identical with those produced by the accident. A quantity of the ammunition which caused the accident was accordingly procured, and on examining it, over 100 double-bulleted cartridges were found. The original cause was finally traced to an automatic machine by means of which the cartridge had been "bulleted."

It is pointed out that the error would have been avoided had some system of weighing the filled cartridges been used, and also by a more accurate system of gauging, since the faulty cartridges were all found to be too high to gauge.—B. J. S.

Nitrous acid; Oxidation of —— by hydrogen peroxide. Determination of nitrate in presence of nitrite. [*Determination of nitrogen in nitrocellulose.*] M. Busch. XXIII., page 499.

Heat-test papers; Supply of ——. Home Office Circular, May 14, 1906.

THIS circular, which is issued by the Explosives Department, states that, in consequence of certain applications that have been made for the supply by Dr. Dupré of heat-test papers, it has been decided that these papers will be supplied to any firm desiring to obtain the same, at a price of 10s. 6d. per thousand. It is necessary that heat-test papers should be kept for one month before being issued for use, and it is, therefore, desirable that requirements, if any, should be notified one month before the papers are required. In accordance with the heat-test memorandum, the papers should be kept in the dark, and will remain good for six months or more, but should be tested from time to time in the manner described.

ENGLISH PATENTS.

Smokeless powders; Impts. in ——. A. T. Cocking and Kynoch, Ltd., Birmingham. Eng. Pat. 15,564, July 26, 1905.

THE object of the invention is to produce a propellant having good ballistics, which on combustion produces a solid residue which will act as a lubricant and neutralise the acid products of combustion. The explosive is made by incorporating nitroglycerin (30—40 parts) and nitrocellulose (50—60 parts) with 2·5 parts of vaseline, and 2·5 parts of olive oil, the latter being used to lower the temperature of explosion.

A carbonate of an alkali or alkaline-earth metal, or a salt which on combustion will produce a carbonate, is also introduced. In practice, it has been found best to use a mixture of a barium salt, sufficient to give 2·8 parts of barium carbonate, and a potassium salt sufficient to give 0·55 part of potassium carbonate; thus, 0·9 part of potassium tartrate may be used together with 4·0 parts of barium tartrate. The explosive is finally manufactured in the form described in Eng. Pat. 12,892 of 1905 (this J., 1906, 337).—B. J. S.

Steel guns; Protection of —— from the erosive effects of cordite and similar gases. G. C. J. Topp. Eng. Pat. 12,635, June 19, 1905. XIB., page 484.

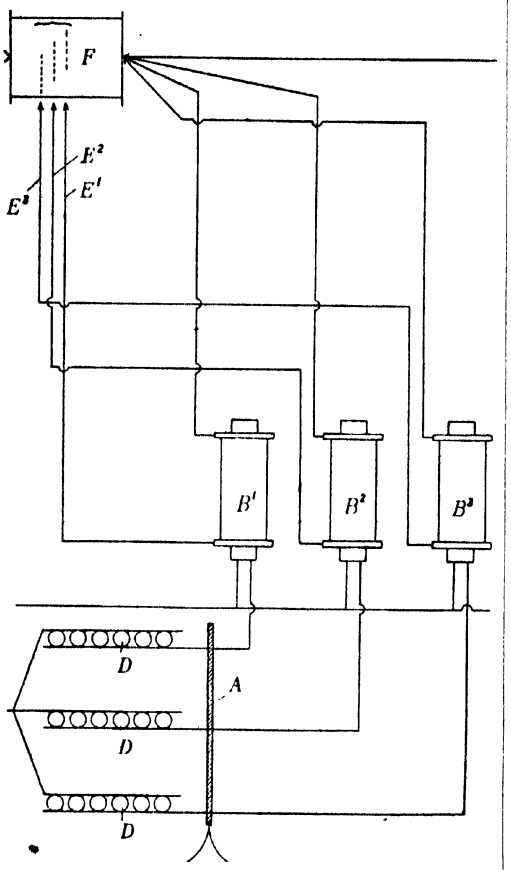
UNITED STATES PATENT.

Explosives; Process for completely exploding high ——. H. von Dahmen, Vienna. U.S. Pat. 818,939, April 24, 1906.

THE invention consists in the use of a mixture of lead peroxide, sulphur, carbon and potassium nitrate as an exploder for high explosives, such as picric acid and gun-cotton.

The exploder is either mixed with the high explosive or enclosed in a tube and inserted into it, firing being effected by means of a gunpowder fuse.—B. J. S.

FRENCH PATENTS.



Explosives; Process for the production of new military and mining ——. Dinamite Nobel Soc. Anon. Fr. Pat. 360,787, Oct. 17, 1905. Under Int. Conv., Nov. 9, 1904.

DICYANDIAMIDINE, guanidine nitrate, nitroguanidine and nitrosoguanidine may be used as cooling agents in propellants, and result in lower temperatures of explosion without loss of ballistics. Thus 25 parts of nitroguanidine may be incorporated with 45 parts of nitroglycerin (or nitrobenzene) and 30 parts of nitrocellulose. These compounds may also be mixed with picric acid, and thus give powerful explosives which are not sensitive to shock. The following mixture is given: 30—60 parts of nitroguanidine, 0—20 parts of potassium nitrate, 20 parts of picric acid, 0—40 parts of ammonium nitrate, 0—10 parts of dinitrotoluene. Manganese dioxide, aluminium and nitronaphthalene may also be introduced, and the mixture may be protected from moisture by adding resin or shellac.

To prepare nitroguanidine, dicyandiamide is converted by dilute sulphuric acid into dicyandiamidine, and the resulting solution, after precipitation with barium carbonate and filtration, is boiled for a long time and evaporated. The guanidine carbonate thus obtained is nitrated with a mixture of fuming nitric and fuming sulphuric acids.—B. J. S.

Explosives; Method and apparatus for measuring the velocity of detonation of ——. H. Mettegang. Fr. Pat. 359,865, Nov. 27, 1905.

IN order to measure the velocity of detonation of an explosive such as dynamite, a modification of Siemens' apparatus for measuring small intervals of time is used. The apparatus consists of a series of induction coils, B^1, B^2, B^3, with one secondary terminal of each, connected to a revolving drum, F, coated with lampblack. The other secondary terminals are connected with a series of bright metallic points, E^1, E^2, E^3, which are placed close to the surface of the drum. The positive leads of the primary of each coil are made to cross the charge of explosive, A, the velocity of detonation of which is required, and may be connected through a resistance of electric lamps, D, to a main circuit. At the moment the current in the primary is interrupted, a stream of sparks is set

up in the secondary, which impinge on the black surface of the drum. By this means the time required for the explosive to burn, from the point at which one primary wire crosses it to the next, is recorded on the drum.
—B. J. S.

Explosives; Manufacture of ammonium nitrate ——. G. Reschke. Fr. Pat. 360,349, Dec. 12, 1905.

AMMONIUM nitrate can be utilised for fire-damp explosives by mixing it with a quantity of carbonaceous matter greater by 1 per cent. than the amount required to give carbon monoxide and hydrogen as products of explosion. If required, a nitro-body, except nitroglycerin, may also be added, in quantity greater by 3 per cent. than the amount necessary to give carbon monoxide and hydrogen. Suitable mixtures are as follows:—(1) Turmeric, 40·8 per cent.; ammonium nitrate, 59·2 per cent. (2) Sugar, 35 per cent; ammonium nitrate, 65 per cent. (3) Dinitrobenzene, 1 per cent.; fennel flour (farine de fenouil), 30 per cent.; ammonium nitrate, 69 per cent. (4) Dinitrobenzene, 1 per cent.; naphthalene, 12 per cent.; ammonium nitrate, 87 per cent.

The process of grinding should be carried further than with ordinary ammonium nitrate explosives. By varying the proportion of carbonaceous matter, explosives of any required degree of power can be obtained, which are cheap and not deliquescent.—B. J. S.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 446.)

INORGANIC—QUANTITATIVE.

Zinc: Titration of —— with potassium ferrocyanide. E. Murmann. Z. anal. Chem., 1906, **45**, 174—181.

THE author has investigated the magnitude of the errors which occur in titrating zinc with potassium ferrocyanide, using a uranium salt as indicator. He finds that the presence of large quantities of salts, in particular ammonium chloride, only slowly increases the amount of ferrocyanide required by a given quantity of zinc solution. Increasing quantities of hydrochloric acid similarly increase the ferrocyanide necessary, but the acid cannot be used in larger quantities than 20 c.c. to 100—150 c.c. of liquid. To avoid the presence of nitric acid it is advisable to use uranyl chloride instead of uranyl nitrate as indicator. Zinc salts and potassium ferrocyanide can be titrated directly, using the uranium salt indicator in the solution instead of the more lengthy drop test method. The solution is maintained almost boiling, excess of ferrocyanide is first added, giving a brown coloration and the solution is then titrated back till this changes to blue grey, the transformation being quite sharp. Molybdenum and tungsten salts were found to be unsuited for use as indicators.—E. F. A.

Cadmium: Determination of ——, in a volatile or organic salt. H. Baubigny. Comptes rend., 1906, **142**, 959—961.

IF the solution to be treated contain a chloride or bromide, the author's method (this J., 1906, 394) is no longer applicable, because the sulphide obstinately retains traces of chloride or bromide, which are volatilised during the incineration of the filter. In such cases, after thorough washing, the sulphide is rinsed off the filter, allowed to settle out, and the washings (almost free from sulphide, and practically free therefore from contained halide) decanted through the filter, which can then be incinerated without loss. The sulphide is next added, and the conversion into sulphate proceeded with.

In the case of organic salts there is no difficulty. To the solution an excess of sulphuric acid is added. If the organic acid be insoluble, it is precipitated and filtered off; if soluble, its presence in solution does not interfere with the carrying out of the process as described.—J. T. D.

Nickel; Quantitative determination of small quantities of —— in organic substances. H. W. Armit and A. Harden. Roy. Soc. Proc., 1906, **77B**, 420—423.

THE method may be divided into three stages—(1) incineration, (2) separating and (3) estimating:

Ashing.—The substance is evaporated to dryness in a porcelain crucible over a water-bath, further dried by heating in a hot air oven or with a Bunsen flame, burned over a Fletcher burner and incinerated in the blow-pipe flame. The ash is evaporated to dryness on the water-bath with 10 c.c. of pure hydrochloric acid, this process being repeated, and is then extracted with water containing a small amount of hydrochloric acid.

Separation.—The iron and the phosphates are first removed by precipitation with excess of ammonia and filtration, and the process is repeated three times, the precipitate being redissolved each time. The method of procedure varies somewhat according to the tissues investigated. The united filtrates are evaporated, the residue dissolved again in dilute hydrochloric acid and saturated hot with sulphuretted hydrogen. The filtrate from the precipitated sulphides is evaporated to dryness, redissolved in water and the nickel precipitated with pure sodium hydroxide. The nickel oxide is washed, dissolved in hydrochloric acid and the solution made up to a definite volume.

Estimation.—The best results were obtained using *a*-dimethylglyoxime, which forms a scarlet red compound with nickel in presence of ammonia, as a colorimetric indicator. To a few c.c. of the nickel solution 0·5 c.c. of

ammonia and 0·5 c.c. of dimethylglyoxime are added, and after development of the colour the whole is diluted to 30 c.c. and compared with standards. The method has the advantages over the ammonium sulphide method that small traces of iron do not interfere with the final colour, smaller quantities of nickel can be accurately estimated and it is easier to work in a bad light with the pink than with the brown coloration—E. F. A.

Nitrous acid; Oxidation of —— by hydrogen peroxide. Determination of nitrate in presence of nitrite. [*Determination of nitrogen in nitrocellulose.*] M. Busch. Ber., 1906, **39**, 1401—1402.

Nitrous acid in acid solution is oxidised quantitatively and almost instantaneously to nitric acid by hydrogen peroxide at 60°—70° C. The nitric acid may be determined gravimetrically as nitron-nitrate (see this J., 1905, 291, 458, 638). For the determination of nitrite by this method, a quantity of the substance containing 0·1—0·2 grm. of nitrite is dissolved in about 50 c.c. of water, 20 c.c. of a 3 per cent. neutral solution of hydrogen peroxide are added, and the mixture heated to 70° C.; 20 c.c. of pure 2 per cent. sulphuric acid are then introduced at the bottom of the containing vessel, by means of a dropping funnel, the liquid is heated nearly to boiling, and the nitric acid precipitated by 12 c.c. of nitron acetate solution.

For the determination of nitric acid in presence of nitrous acid, the latter is determined in a portion of the solution by titration with permanganate. In another portion the nitrous acid is oxidised by hydrogen peroxide, and the total nitric acid is then determined as nitron-nitrate.

The author also gives a preliminary note on a new method for the determination of nitrogen in nitrocellulose. By boiling nitrocellulose with caustic alkali solution in presence of hydrogen peroxide, the whole of the nitrogen is obtained in the form of nitrite and nitrate. On acidifying the solution, the nitrous acid is oxidised by the hydrogen peroxide, and the total nitrogen in the form of nitric acid can be determined by precipitation as nitron nitrate. —A. S.

ORGANIC—QUALITATIVE.

Walnut oil; Detection of foreign oils in ——. P. Balavoine. Schweiz. Woch. Chem. und Pharm. 1906, **44**, 224—226.

The author has carried out some tests with the method of Bellier (Ann. Chim. anal. appl., 1905, 52), based on the insolubility of the solid fatty acids in 70 per cent. alcohol, for the detection of admixture of other oils with walnut oil. One c.c. of the oil to be tested is treated in a test-tube with 5 c.c. of alcoholic solution of potassium hydroxide (16 grms. in 100 c.c. of 92 per cent. alcohol); a similar tube is prepared with the same quantity of walnut oil of known purity; the two tubes are heated, side by side, on the water-bath, without boiling, until the oil has dissolved; they are then corked and heated at 70° C., for 30 minutes. Exactly enough 25 per cent. acetic acid, is then added to neutralise the amount of potassium hydroxide present. The tubes are then recorked, and placed in a bath at 25° C. until their contents have reached that temperature. They are then removed to another bath at 17°—19° C. and frequently agitated, the time at immersion being noted. Under these conditions pure walnut oil requires a markedly longer cooling before showing a precipitate of fatty acids than an impure sample. Poppyseed oil approaches nearest to walnut oil in the solubility of its fatty acids, but an addition of 10 per cent. of this oil to walnut oil will hasten the formation of the precipitate by three to four minutes. An admixture of 5 per cent. of olive oil causes a precipitate six minutes before one forms in the standard with pure oil; 5 per cent. of sesamé oil, nine minutes sooner; 5 per cent. of cottonseed oil, 16 minutes; 5 per cent. of arachis oil, nine minutes sooner. It is found that walnut oil which has been kept for some time produces the precipitate sooner than that freshly prepared.—J. O. B.

Fluorine in alimentary products [*and wine, beer, &c.*]; *Optical method for the detection of ——.* J. Ville and E. Derrien. Bull. Soc. Chim., 1906, **35**, 239—246.

The method is based on the fact that fluorides when added to methæmoglobin alter the spectrum of the latter and cause a separate absorption band to appear in the orange part of the spectrum. The methæmoglobin solution used is prepared by treating defibrinised blood with four times its volume of 0·1 per cent. potassium oxalate solution, filtering the mixture and adding a trace of potassium ferricyanide to the filtrate. The reagent thus obtained is added to the solution to be tested in the proportion of 1 c.c. to 25 c.c. and the solution then examined spectroscopically; the solution under examination must be clear, colourless and deprived previously of any constituents which would precipitate the blood-reagent. In the case of wine, 100 c.c. of the latter are evaporated until all the alcohol has been removed, water is added to make up the original volume, the solution is treated with 2 grms. of freshly precipitated manganese dioxide and filtered; 50 c.c. of the filtrate are then mixed with 5 c.c. of egg-albumin dissolved in twice its volume of 1 per cent. potassium oxalate solution, the mixture is heated to boiling, cooled and filtered; 25 c.c. of the filtrate are now treated with 1 c.c. of the blood-reagent, and examined with the spectroscope. In testing beer it is sufficient to deprive the beverage of its alcohol and carbon dioxide, and then to add the reagent, whilst milk simply requires curdling and filtering before adding the reagent. To detect fluorides in butter a portion of the sample is mixed with a little water and heated, the aqueous portion filtered, and the filtrate treated with the reagent. In the case of meat, the solution, obtained on macerating the sample with water, is boiled, filtered, and the filtrate used for the test. It is stated that the method will detect the presence of 0·08 grm. of sodium fluoride per litre of wine, &c.—W. P. S.

Morphine; Characteristic colour reaction of ——. D. Radulescu. Bul. Soc. de Sciinte din Bucuresci, **14**, 602—605. Chem. Centr., 1906, **1**, 1378.

If to a solution containing morphine a fragment of sodium nitrite and some acid be added, and then before the evolution of gas has ceased, the liquid be made alkaline with a concentrated solution of potassium hydroxide, a coloration varying from pink to deep ruby red, according to the quantity of morphine present, is produced. The coloured substance is not extracted by ether, chloroform, carbon bisulphide or benzene. The coloration disappears on acidifying the solution, but reappears if alkali be added to the acid liquid, provided the latter has not been allowed to stand for too long a time. It is stated that one part of morphine in 300,000 can be detected by this reaction. —A. S.

Ethyl glyoxylate; Characteristic reaction of ——. Action of ammonia on the ether and its derivatives. L. J. Simon and G. Chavanne. Comptes rend., 1906, **142**, 930—933.

Ethyl glyoxylate treated with aqueous ammonia forms a precipitate which, at first white, passes through yellow, orange and red tints, becoming finally a bluish-black. At the same time the ammoniacal fluid assumes a dark red hue. The change takes place slowly in cold solutions, rapidly on heating, and is also brought about by ammonium carbonate, sulphate or chloride, provided alkali be also added. The precipitate forms a dull black substance, $C_4H_8O_4N_2$, which dyes cotton and silk a dirty blue violet, the colour being fast to soap, but not to light. The esters of other closely related acids do not give the coloration, which thus allows of a delicate test for ethyl glyoxylate. It is not, however, shown by the salts of glyoxylic acid or by other derivatives not containing the ester group, whilst ammonia converts derivatives obtained from the aldehydic portion of the molecule, into amides which show no such coloration. The coloration resembles in some ways the murexide test for uric acid.—E. F. A.

ORGANIC—QUANTITATIVE.

Pentoses; New method for the quantitative determination of ——. A. Jolles. Z. anal. Chem., 1906, **45**, 196—204.

The method is based on the estimation of the furfural formed on distilling pentoses, by means of bisulphite, the excess of bisulphite being determined with iodine. The adverse influence of excess of acid and salts on the titrations rendered a modification of Tollen's hydrochloric acid distillation method necessary. The pentose is heated with hydrochloric acid in a flask through which steam is driven throughout the operation, care being taken to keep at least 100 c.c. of liquid in the flask. The distillate is measured and an aliquot portion neutralised with caustic soda and left for two hours with an excess of bisulphite which is susequently titrated back with iodine solution. The presence of any large excess of acid or of inorganic salts renders the titration inaccurate.—E. F. A.

Cocoa; Determination of fat in ——. Tschaplowitz. Z. anal. Chem., 1906, **45**, 231—235.

In extracting fat from cocoa with ether, the difficulty is often experienced that the ether only percolates through the mass very slowly and but partially attacks and extracts the unbroken oil cells. The author carries out the extraction in a boiling flask, of about 80 c.c. content, with a long neck, which is graduated from 73 to 77 c.c. Enough cocoa to yield from 1 2 grms. of oil is weighed into the flask and boiled for a few minutes with 10—15 c.c. of alcohol, whereby it becomes finely divided. About as much ether is added and the boiling repeated, after which the flask is filled up with ether, well shaken and stood aside. When the solid matter has subsided, 50 c.c. of the clear liquid are removed with a pipette and evaporated to dryness. The oil is redissolved in a little ether, filtered through cotton wool and weighed after drying.—E. F. A.

Methyl alcohol in formaldehyde solutions; Determination of ——. O. Blank and H. Finkenbeiner. Ber., 1906, **39**, 1326—1327.

The commercial 40 per cent. solutions of formaldehyde generally contain 12—18 per cent. of methyl alcohol, which prevents them from becoming turbid in cold weather. The methyl alcohol is determined in an indirect manner by combustion by chromic acid. One grm. of the formaldehyde is weighed out and is then added to a mixture of 50 c.c. of a 2.N-solution of chromic acid and 20 c.c. of pure concentrated sulphuric acid. After standing for about 12 hours, or a shorter time if heat be employed, the liquid is diluted to 1 litre and 50 c.c. are titrated with N/10 thiosulphate after the addition of a crystal of potassium iodide. The total quantity of oxygen consumed being thus determined and the percentage of formaldehyde being known, the quantity of methyl alcohol can be calculated.—J. F. B.

Acetone; Determination of ——. A. Jolles. Ber., 1906, **39**, 1306—1307.

The solution of acetone is treated with three or four times the necessary quantity of a standardised solution of sodium bisulphite, and the excess of bisulphite is titrated back with iodine after 30 hours' standing. The reaction is based on the combination of 1 mol. of acetone with 1 mol. of bisulphite with the production of the sodium salt of the corresponding sulphonic acid (compare similar method for furfural, this J., 1906, 201). The reaction proceeds more slowly than in the case of aldehydes and the duration of contact cannot be curtailed; it is, therefore, advisable to conduct a blank experiment with the bisulphite solution under the same conditions, in order to correct any alterations in its value.—J. F. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 447.)

Carbon suboxides. Berthelot. Comptes rend., 1906, **142**, 533—537.

The analogy between carbon monoxide and methylene is pointed out and on this supposition carbon monoxide should form polymerides analogous to compounds of the acetylene series. This series of suboxides should by pyrogenetic reactions give rise to new series of compounds containing less oxygen. In conformity with this supposition the following suboxides of carbon are already known to exist (compare following abstract).

The suboxide, C_4O_3, corresponding to an anhydride of tartaric acid was first discovered by Brodie and subsequently investigated by Berthelot. On heating, this forms a compound, C_8O_3, corresponding to an anhydride of dihydroxyphthalic acid, which, in turn, when exposed to heat, forms other suboxides richer in carbon. Lastly, the existence of a compound, C_2O, corresponding to glycollic anhydride, was indicated by the author in 1891.

—E. F. A.

Carbon suboxide. I. O. Diels and B. Wolf. Ber., 1906, **39**, 689—697.

Ethyl malonate, when heated with phosphorus pentoxide, is decomposed into ethylene, carbon dioxide, and a new gas,—carbon suboxide. This is most conveniently prepared by slowly distilling ethyl malonate in a vacuum of 12 mm. over a large excess of phosphorus pentoxide heated to about 300° C. Any unattacked ester is retained in a well-cooled wide test-tube through which the products of the reaction pass to a specially constructed piece of apparatus cooled in liquid air in which ethylene, carbon dioxide, and the new product are condensed. Its contents are subsequently allowed to boil away at ordinary temperatures, when the carbon suboxide, now a colourless liquid, remains behind. The greatest care must be taken to exclude all traces of moisture.

Carbon suboxide is a colourless, refractive, mobile liquid having a pungent acrolein or mustard-oil like smell. The vapour has an irritating effect on the eyes, nose, &c. It boils at + 7° C. and burns with a smoky blue flame. It has the composition C_3O_2, is monomolecular and probably has the formula OC:C:CO; when exploded with 2 vols. of oxygen, it produces 3 vols. of carbon dioxide.

Carbon suboxide behaves as an anhydride of malonic acid and has the properties of an unsaturated substance. Both in constitution and properties it resembles the nickel tetracarbonyl described by Mond, Langer, and Quincke (this J., 1890, 808). It dissolves in water, forming malonic acid. Mixed with aniline in ethereal solution, the formation of malonanilide takes place even below 0° C. An ethereal solution of ammonia converts it almost instantaneously into malonamide. It reacts with anhydrous gaseous hydrogen chloride to form malonyl chloride.

When kept for a day of two at 15° C. the liquid at first colours yellow, then yellow flakes are formed and finally the whole is converted into a dark red solid, which, when powdered, is almost black and contains about 52 per cent. of carbon. This dissolves in cold water with a remarkable intense eosine-red coloration. The decomposition takes place much more rapidly at 37° C., a hard blackish-red product, containing about 75 per cent. of carbon, being obtained. This is only partially soluble in water and gives a dark brown solution. At 100° C. the decomposition is instantaneous. The first product is probably identical with the compound C_4O_3, and the latter with the compound C_8O_3, described by Berthelot (see preceding abstract).—E. F. A.

Prizes.

The Council of the Society of Dyers and Colourists announce that funds have been placed at their disposal for distribution, in the form of prizes for the solution of technical problems.

List of Problems and Prizes.

1.—Prize of £20 for a full investigation of the average degree of tendering brought about in cotton yarn of various qualities by—

(*a*) Cross dyeing with acid colours; and

(*b*) Dyeing Aniline Black,

with the object of fixing standards for the trade.

2.—Prize of £10 for a practical method of so treating or preparing cotton yarn as to cause it to resist direct dyeing cotton colours. (The object desired is the production of a pattern or mixed effect in the piece dyeing of all cotton goods.)

3.—Prize of £10 for a practical method of dyeing full shades of basic colours on cotton, fast to rubbing.

4.—Prize of £10 for a practical method of causing kemps, when present in yarn or piece goods, to take the dyestuff equally with the accompanying wool.

5.—Prize of £20 for a full investigation of the mordanting properties of various tannin materials, more especially

(*a*) As to the relative affinity for cotton of the tannins of galls, myrabolams, sumach, divi-divi, &c.

(*b*) As to the relative fastness of the colour lakes produced with these tannins and basic colours, in conjunction with antimony, tin, and iron.

(*c*) As to the best method of determining by volumetric analysis, or other means, their relative mordanting power.

6.—Prize of £20 for a cheap and practicable method of producing a good black on Tussur silk.

7.—Prize of £50 for a practical method of so treating with some non-deliquescent substance, cotton piece goods dyed logwood black and heavily filled, as to render them mildew proof in tropical climates without impairing either colour or finish.

Competitors may obtain further details relating to this prize on application to the hon. secretary of the Society.

Rules governing the award of the prizes and general conditions to be fulfilled by competitors.

(1) The prizes are open to all, irrespective of nationality.

(2) Papers will be accepted in English, French, or German.

(3) All papers, &c., sent in for competition must be delivered free to the Honorary Secretary of the Society, on or before December 31st, 1906.

(4) A Committee of three or five adjudicators will be appointed by the Council for each problem. No person directly or indirectly connected with the preparation of any paper sent in for competition shall accept office as an adjudicator for that problem. The names of the Committees of Adjudication will be published in the Journal of the Society immediately after appointment.

(5) The donors of any particular prize shall have the right of appointing one member of the Committee of Adjudication for that prize, such appointment to be subject to the approval of the Council. In cases in which the donors exercise this right, the number of members appointed by the Council under Rule 4 will be reduced to two or four respectively.

(6) All papers, patterns, drawings, &c., sent in for competition should be enclosed in a sealed envelope bearing outside the number of the problem, and the motto of the competitor. This envelope will not be opened until the adjudication is to be made. The paper must also be accompanied by a second sealed envelope bearing the same motto and containing the name and address of the competitor.

(7) Every competitor by submitting his work, thereby agrees to leave himself entirely in the hands of the Committee of Adjudication, whose decision must be accepted as final.

(8) If a question is not completely solved, a competitor may be awarded a portion of the prize offered, and if several competitors have at the same time solved the same problem satisfactorily, the prize may be divided amongst them in equal or unequal parts, according to the respective value of the work submitted, at the sole discretion of the Adjudicating Committee.

(9) No work already published, may be entered for competition, and no work sent in for competition may be published until after adjudication. The depositing of the work with the Society secures for the author priority of discovery from the date at which it was deposited.

(10) Every competitor has the right to take out a patent for his process or invention, but the Society reserves to itself the prior right, after the adjudication has been made, of publishing, either in whole or in part, any of the work submitted. As the patent law of most countries requires that the invention should not have been published previously to the date of application, competitors who desire to patent their inventions should do so before December 31st, 1906, the Society declining all responsibility in this matter. In cases where an inventor has been awarded a prize by the Society before it is patented, he may request that the publication of his paper be adjourned for any period not exceeding six months.

(11) The Society will endeavour, as far as possible, to return unsuccessful papers to the competitors, but they accept no responsibility under this head.

The Hon. Secretary of the Society will be glad to communicate with anyone desiring to include further problems in the above list.

ERNEST T. HOLDSWORTH, *Hon. Sec.*
10, Merton Road, Bradford.

Trade Report.

SWITZERLAND; IMPORT TRADE OF ——.

For. Off. Ann. Series, No. 3572.

THE subjoined table shows the particulars of certain imports during the years 1904-05:—

New Books.

Metallurgical Calculations. By Joseph W. Richards, A.C., Ph.D., Professor of Metallurgy in Lehigh University, &c. Part I. Introduction, Chemical and Thermal Principles. Problems in Combustion. McGraw Publishing Co., New York. 1906. Price, 2 dols. net. E. and F. N. Spon, London.

vo volume, containing 201 pages of subject matter and he alphabetical index. The text is subdivided under the following heads:—I. The Chemical Equation. II. Applications of Thermochemistry. III. Use of the Thermochemical Data. IV. The Thermochemistry of High Temperatures and Thermophysics of Elements and Alloys. V. Thermophysics of Chemical Compounds. VI. Artificial Furnace Gas. VII. Chimney Draft and Forced Draft. VIII. Conduction and Radiation of Heat. IX. Appendix with a Series of Problems.

On the Analysis and Valuation of Oxide of Iron and Lime for Purposes of Gas Purification, with Notes on the Determination of Sulphuretted Hydrogen and Carbon Dioxide in Gas Liquor. By H. Leicester Greville. Walter King, 11, Bolt Court, Fleet Street, London, E.C. 1906. Price, 2s. 6d.

Pamphlet of 8vo size, containing 32 pages of subject matter, and treating of the following points in connection with the above subject:—I. Oxide of Iron as a purifying agent, and its valuation as a raw material and in a spent condition. II. Analysis of oxide of iron supplied for the purposes of Gas Purification. III. Spent Oxide. IV. Estimation of "Blue" in Spent Oxide. V. Analysis of Raw and Spent Lime. VI. Analysis of Spent Lime. VII. Estimation of Sulphuretted Hydrogen and Carbonic Acid in Gas Liquor.

Annual Statement of the Trade of the United Kingdom with Foreign Countries and British Possessions, 1905. Volume 1. Wyman and Sons, Fetter Lane, E.C. [Cd. 2928.] Price 7s. 8d.

Foap. volume of 945 pages, consisting of an introduction, summary statements of British, Foreign and Colonial exports and imports; abstract tables relating to British and colonial trade; detailed statement of imports (*a*) free of duty, (*b*) subject to duty; detailed statement of exports (*a*) manufactured or produced in the United Kingdom, (*b*) foreign and colonial merchandise; coin and bullion, imports from and exports to each country.

Austria-Hungary.—New Customs Tariff (Interim Statement). [Cd. 2917.] Price 1s. 3d.

This return contains a translation of the new Customs tariff of Austria-Hungary as modified by commercial treaties with Germany, Russia, Italy, Belgium and Switzerland. This tariff came into force on the 1st of March last, but it is reported that the Austro-Hungarian Government contemplate negotiations with countries other than those specified, and in that case it is possible that the tariff may be still further modified as a result of such negotiations. In view, however, of the tariff being already in force, the Board of Trade have thought it desirable to issue the present interim return for the immediate information of those interested.

The advantage of all concessions which Austria-Hungary may accord to other countries, as well as the concessions already made to Germany, Russia, Italy, Belgium, and Switzerland, will be extended to the United Kingdom in virtue of the most-favoured-nation clause of the Treaty between the United Kingdom and Austria-Hungary of 5th December, 1876.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

[A.] 11,325. Pickering (Dixon). *See under* XVI.
" 11,434. Morison. Condensing apparatus. May 16.
" 11,475. Guillaume. Baffle plates for column stills. [Fr. Appl., May 26, 1905.]* May 16.
" 11,517. Henderson and Simon, Ltd. Separation of dust and other impurities from air and gases. May 17.
" 11,621. Stevens and Hughes. Filter presses. May 18.
" 11,724. Boult (Manvers and Phillips). Apparatus for creating and maintaining a vacuum.* May 19.
" 11,993. Scheibe. Separation of admixtures from gases and vapours.* May 22.
" 12,210. Potter. Cleansing gases. [U.S. Appl., June 10, 1905.]* May 26.
" 12,223. Haddan (Aktiebolaget Separator). Centrifugal machines.* May 25.
[C.S.] 9952 (1905). Andrews. Furnaces. May 23.
" 10,560 (1905). Hargreaves. Concentrating solutions and obtaining and conveying salts. May 23.
" 13,614 (1905). Gibbons, Masters and Baeddicker. Furnaces, muffles and kilns. May 23.
" 15,119 (1905). Macquisten. Separation of solid particles from each other. May 23.
" 19,795 (1905). Evans (Ges. f. Trockenverfahren). Process for drying by means of rays of light. May 30.
" 20,381 (1905). Theryc. Systems of concentration. May 23.
" 23,424 (1905). Porges and Neumann. Separation of solid bodies from liquids by cooling and apparatus therefor. May 30.
" 4824 (1906). Boas, Rodrigues-Ely and Gauthier. Vessels for containing gas under pressure. May 30.

II.—FUEL, GAS, AND LIGHT.

[A.] 11,279. Bourdos, Rothschild and Sutcliffe. Filaments of incandescent electric lamps. May 14.
" 11,311. Lynde. Production of gas from petrol and other hydrocarbons. May 15.
" 11,409. British Thomson-Houston Co. (General Electric Co.). *See under* VII.
" 11,572. Laycock. Incandescent gas mantles. May 17.
" 11,639. Bloxam (Lux). Metallic incandescence filaments for electric glow lamps. May 18.
" 11,660. Jones. Coke ovens.* May 18.
" 11,797. Schöndeling. Process and device for cleaning coal. May 21.
" 11,810. Lee. Metallic filaments for electric incandescent lamps. May 21.
" 11,925. Allison (Amer. Chemical Eduction Co.). Process of distilling coals and other hydrocarbonaceous substances.* May 22.
[A.] 11,926. Allison (Amer. Chemical Eduction Co.). Apparatus for distilling coals and other hydrocarbonaceous substances.* May 22.
" 11,944. Just, Hanaman, and Verein. Elektricitäts A.-G. Manufacture of incandescing bodies for electric incandescent lamps. May 22.
" 12,055. Cruyt. Apparatus for use in the combustion of hydrocarbons. [Belg. Appl., June 3, 1905.]* May 23.
" 12,127. Grünewald. Carburetting process and apparatus.* May 24.
" 12,128. Grünewald. Carburetting apparatus.* May 24.
" 12,129. Grünewald. Carburetting apparatus.* May 24.
" 12,132. Guttmann. *See under* VII.
" 12,225. Sodeau, and Brady and Martin, Ltd. *See under* XXIII.
" 12,270. Mason's Gas Power Co., and Bentley. Suction gas producers. May 25.
[C.S.] 9864 (1905). Hirsch. Manufacture of incandescing bodies for incandescent lighting. May 23.
" 10,075 (1905). Radcliffe. *See under* VII.
" 10,616 (1905). Fleming. Generating and utilising hydrocarbon vapours for heating and lighting purposes. May 30.
" 10,733 (1905). Hooton and Noble. Producing or enriching coal gas. May 23.
" 10,954 (1905). Woodall and Duckham. Carbonisation of coal in vertical or inclined retorts. May 30.
" 12,176 (1905). Körting. Gas retort settings and regenerator furnaces. May 23.
" 26,108 (1905). Harry. Mantles for incandescent gas burners. May 23.
" 3006 (1906). Winand. Production of a working medium for internal combustion motors. May 23.
" 4230 (1906). Holmes, Holmes and Cameron. Apparatus for extracting tar from illuminating gas. May 30.
" 8866 (1906). Page (Doherty). Gas calorimeters. May 30.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[A.] 11,311. Lynde. *See under* II.
[C.S.] 4230 (1906). Holmes, Holmes and Cameron. *See under* II.
" 4427 (1906). Coulson. Process for solidifying tar. May 30.
" 8757 (1906). Pagès and Camus. Manufacture of acetone. May 30.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 11,479. Johnson (Kalle und Co.). Manufacture of leuco compound of thio-indigo-red. May 16.
" 11,480. Johnson (Kalle und Co.). Manufacture of a condensation product from thioindoxyl derivatives with isatin, and its employment in dyeing and printing. May 16.
" 11,759. Meister, Lucius und Brüning. Manufacture of an azo dyestuff and of colour lakes therefrom. [Ger. Appl., July 12, 1905.]* May 19.
" 11,760. Imray (Soc. Chem. Ind. in Basle). Manufacture of red, violet and blue vat dyeing dyestuffs.* May 19.
" 12,243. Johnson (Badische Anilin und Soda Fabrik). Production of indoxylic compounds. May 25.
[C.S.] 19,100 (1905). Newton (Bayer und Co.). *See under* XIII*A*.

[C.S.] 20,359 (1905). Cooper (Bayer und Co.). Manufacture of a dyestuff of the anthraquinone series and of intermediate products for use therein. May 23.

„ 22,412 (1905). Sachs. Manufacture of aminophenols. May 23.

„ 22,519 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters containing halogen. May 30.

„ 22,697 (1905). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of disulphonic acids of dianisidine and diphenetidine. May 30.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 11,254. Hansdorf. Apparatus for treating fabrics with liquids.* May 14.

„ 11,285. Möller-Holtkamp. *See under* XIV.

„ 11,480. Johnson (Kalle und Co.). *See under* IV.

„ 11,669. Taghani. Process for dyeing indigo resist articles in the continuous vat. May 18.

„ 11,758. Imray (Meister, Lucius und Brüning). Machines for dyeing or printing in shaded colours or prints. May 19.

„ 11,836. Wagstaff. Machines for washing fibres. May 21.

„ 11,876. Abel (Act.-Ges. f. Anilinfabr.). Dyeing furs, hairs, feathers, or the like, and a material therefor. May 21.

„ 12,017. Smith. Apparatus for carbonising vegetable matter in animal fibres, rags, and the like. May 23.

„ 12,080. Weiss. Process and composition for dry cleaning fabrics.* May 23.

„ 12,117. Wilkinson. Apparatus for bleaching or dyeing hanks, cops, and other fibrous materials.* May 24.

[C.S.] 22,940 (1905). Mann. Glossing and gassing machine for silk and other fine threads. May 23.

VI.—COLOURING WOOD, LEATHER, PAPER, ETC.

[C.S.] 11,040 (1906). Lamb and Rennie. Printing on leather. May 30.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 11,371. Tchernac. Process for separating alkali cyanides from their solutions in water.* May 15.

„ 11,409. British Thomson-Houston Co. (General Electric Co.). Manufacture of tungsten compounds and the production of lamp filaments therefrom. May 16.

„ 11,565. Imray (Meister, Lucius und Brüning). Process for dehydrating sodium hydrosulphite containing water of crystallisation. May 17.

„ 11,767. Consortium f. Electrochem. Ind. Production of calcium hydride. [Ger. Appl., May 19, 1905.]* May 19.

„ 11,770. Fairweather (Chem. Fabr. in Billwärder vorm. Heil und Sthamer). Method of decomposing chrome iron ore to form chromates. May 19.

„ 11,800. Hill. Revolving black ash furnaces. May 21.

„ 11,820. Benton. Kilns for burning lime. May 21.

„ 11,902. Leslie. Manufacture and recovery of carbonic acid. May 22.

„ 11,979. Von Foregger. Apparatus for generating oxygen gas. [U.S. Appl., Feb. 8, 1906.]* May 22.

„ 11,981. Brindley. Generation of oxygen gas. [U.S. Appl., April 14, 1906.]* May 22.

[A.] 12,132. Guttmann. Utilising waste nitrate of soda and the preparation of an improved fuel. May 24.

„ 12,209. Potter. Treatment of silicon monoxide. [U.S. Appl., June 14, 1905.]* May 25.

„ 12,246. Jaubert. Preparation of oxygen by decomposition of oxygenated salts. [Fr. Appl., May 29, 1905.]* May 25.

„ 12,262. Jaubert. Manufacture of oxygen briquettes. [Fr. Appl., May 29, 1905.]* May 25.

[C.S.] 10,075 (1905). Radcliffe. Treatment of certain products of ammoniacal liquor. May 23.

„ 11,347 (1905). Thompson (Goldschmidt and Polzinius?.) *See under* XIIIA.

„ 26,728 (1905). Pawlikowski. Production of endothermic chemical compounds. May 30.

„ 1764 (1906). Noerdlinger and Noerdlinger. Recovery of cyanogen from waste waters, solutions, &c., and rendering the liquids innocuous. May 30.

„ 3121 (1906). Winand. Production of oxygen for internal combustion engines. May 30.

„ 5428 (1906). Ray. Manufacture of common salt. May 23.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 12,159. Slingluff. Glass furnaces. [U.S. Appl., June 29, 1905.]* May 24.

[C.S.] 15,630 (1905). Bredel. Production of a molten mass of rock quartz at a relatively low temperature. May 30.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 11,361. Jones. Heat insulating material. May 15.

[C.S.] 10,902 (1905). Smith and Atherton. Asphalt composition for road making, &c. May 30.

„ 5955 (1906). Klee. Manufacture of artificial stone plates. May 23.

X.—METALLURGY.

[A.] 11,486. Fletcher and Digby. Manufacture of a metallic alloy. May 16.

„ 11,586. Penn. Metallic alloy. May 18.

„ 11,698. Swain. Method of coating iron or steel with tin. May 19.

„ 11,709. Prescott. Method of coating cast iron or steel with non-corrosive metals. May 19.

„ 11,770. Fairweather (Chem. Fabr. in Billwärder). *See under* VII.

„ 11,974. Hadfield. Manufacture of magnetic material. May 22.

„ 12,130. Grünewald. Case-hardening iron or steel.* May 24.

„ 12,185. Cowper-Coles. Manufacture of silver alloys. May 25.

„ 12,266. Cowper-Coles. Production of metals with special physical properties. May 26.

[C.S.] 10,869 (1905). MacIvor and Fradd. Treatment of nickel ores or oxidised nickel mattes. May 23.

„ 24,002 (1905). Walker. Means for neutralising noxious fumes or gases in blasting operations. May 23.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 11,498. Trunkhahn. Process of obtaining electrolytic metallic deposits.* May 16.

„ 11,675. Brindley. Effecting fusion of materials by electricity.* May 18.

[A.] 11,865. Cowper-Coles. Anodes. May 21.
„ 11,950. Hess. Insulating material. May 22.
„ 11,998. Whitehead and Marino. Agglutinant for consolidating active accumulator material. May 23.
„ 12,205. Möllenbruck and Dielmann. Carbon electrodes. May 25.
„ 12,329. Röchling and Rodenhauser. Electric furnaces.* May 26.
[C.S.] 7133 (1905). Fellows, and Pickup and Tice. Electric regenerative battery. May 23.
„ 11,654 (1905). Schanschieff. Accumulator plates. May 30.
„ 4579 (1906). Ozonair, Ltd., and Joseph. Apparatus for ozonising air. May 23.
„ 9164 (1906). Petersson. Electric furnaces for treating gases. May 23.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[A.] 11,622. Iveson and Wilson. Apparatus for pressing and varying the temperature of soap, fat, or like substances. May 18.
„ 11,877. Lanza. Filtering apparatus for extracting stearine from fatty acids in sulpholeic acid solution.* May 21.
„ 11,983. Metz and Clarkson. Process of bleaching oils and fats.* May 22.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(A.)—PIGMENTS, PAINTS.

[A.] 11,230. Griffiths. Pigments. May 14.
„ 11,759. Meister, Lucius und Brüning. *See under* IV.
[C.S.] 11,347 (1905). Thompson (Goldschmidt and Polzinusz). Manufacture of white lead and mixtures of the same with oxide of lead. May 30.
„ 10,100 (1905). Newton (Bayer und Co.). Manufacture of colouring matter lakes. May 30.

(C.)—INDIA-RUBBER.

[C.S.] 25,846 (1905). De Laski and Thropp. Manufacture of rubber cloth. May 30.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

[A.] 11,285. Möller-Holtkamp. Manufacture of clear neutral size suitable for all kinds of yarn.* May 14.
[C.S.] 10,227 (1905). Calico Printers' Association, and Warr. Treatment of serum or blood albumen. May 23.
„ 7010 (1906). Lobb. Process and composition for treating leather. May 30.

XV.—MANURES, ETC.

[A.] 11,215. Allibon. Apparatus for the manufacture of artificial manures. May 14.

XVI.—SUGAR, STARCH, GUM, ETC.

[A.] 11,325. Pickering (Dixon). Continuous centrifugal separator for treating sugar and other materials. May 15.
„ 12,291. Jowson. Manufacture of starch hydrolytic products. May 26.
[C.S.] 8661 (1905). Thomas and Howe. Method of clarifying juices in the manufacture of sugar. May 23.

XVII.—BREWING, WINES, SPIRITS, ETC.

[A.] 12,227. Takamine. Diastatic substance and method of producing the same.* May 25.
[C.S.] 10,783 (1905). Hyde. Process of brewing and appliances employed therewith. May 30.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

[C.S.] 14,794 (1905). Haaman and Diamant. System of sterilisation. May 30.

(B.) SANITATION; WATER PURIFICATION.

[A.] 11,848. Schmidt. Process of purifying water. [Ger. Appl., May 21, 1905.]* May 21.
„ 11,980. Brindley and von Foregger. Regenerating and purifying vitiated air. [U.S. Appl., March 9, 1906.]* May 22.
[C.S.] 16,204 (1905). Aslatt. Process for promoting combustion of towns' refuse in destructor furnaces. May 30
„ 1764 (1906). Noerdlinger and Noerdlinger. *See under* VII.

(C.)—DISINFECTANTS.

[A.] 11,445. Rosenberg. Treatment of materials for rendering them aseptic. May 16.
„ 11,555. Gronwald. Sterilisation of corks. [Ger. Appl., May 18, 1905.]* May 17.
„ 12,299. Lehmann. Disinfecting process.* May 26.

XIX.—PAPER, PASTEBOARD, ETC.

[A.] 11,632. Coale. Manufacture of artificial cork.* May 18.
[C.S.] 1377 (1906). Armengaud. Manufacture of paper by the web machine. May 30.
„ 5851 (1906). Erfurt. Direct utilisation of the waste water of a paper machine. May 30.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

[A.] 11,574. Johnson (Verein. Chinnfabr. Zimmer und Co.). Manufacture of boracic acid esters. May 17.
„ 11,725. Fritzsche und Co. Manufacture of neutral oxychinolin salts. [Ger. Appl., June 2, 1905.]* May 19.
[C.S.] 11,219 (1905). Ellis (Merck). Manufacture of dialkylbarbituric acids. May 30.
„ 15,118 (1905). Nicolaidi. Manufacture of an officinal preparation of phosphoric acid. May 23.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[A.] 11,304. Schreiber. Impts. in the carbon process by enhancing the keeping properties of the tissue. May 15.
[C.S.] 16,999 (1905). Smith. Photographic film. May 30.
„ 27,088 (1905). Dischner. Production of photographs. May 23.

XXII.—EXPLOSIVES, MATCHES, ETC.

[A.] 11,938. Seip, and Curtis's and Harvey, Ltd. Smokeless propellant powders. May 22.
„ 12,131. Muir and Boor. Igniting compositions for match heads and the like. May 24.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

Official Notice.

ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Manchester, on Wednesday, July 11th next and following days. A programme and request form accompanied the May 31st issue of the Journal.

In accordance with the provisions of Rule 18 of the By-Laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council (see Journal for April 30th, p. 341) will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Eustace Carey has been nominated to the office of President under Rule 8; Dr. E. G. Love, Mr. A. Gordon Salamon, and Mr. Chas. Wightman have been nominated Vice-Presidents under Rule 8; and Dr. E. Divers, F.R.S., has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Dr. F. J. Smale, Mr. Thos. Tyrer, Sir Thos. Wardle, and Mr. R. C. Woodcock have been nominated, under Rule 18, to fill four vacancies among the Ordinary Members of Council. No ballot will be required. The member's ticket accompanies this issue of the Journal.

ALTERATION OF BY-LAWS.

With a view to facilitate the voting of members residing abroad, notice is hereby given, in accordance with Rule 35 of the By-laws, that the Council will propose to the forthcoming Annual General Meeting the amendment of the Society's By-laws as follows:—

1. Rule 18. (*a*) That the words "At least two months before the date of each Annual General Meeting," in the first and second lines thereof, be replaced by the words, "In the second issue of the Society's Journal for the month of April in each year."

(*b*) That the words "date of that meeting," in the fourth line thereof, be replaced by the words "Annual Meeting next ensuing."

(*c*) That the words "At least one month before the date of;" in the sixth line from the end thereof, be replaced by the words "not later than the last day of May prior to."

(*d*) That the words "to the election to take place at which it refers" in the fifth line from the end thereof, be replaced by the words "at which the election to which the nomination refers is to take place."

2. Rule 19.—That the words "at least five days before the commencement of the said meeting," in the two last lines thereof, be replaced by the words, "in the second issue of the Society's Journal for the month of May."

Deaths.

Birmingham Section.

Meeting held at Birmingham on Thursday, February 15th, 1906.

PROF. FRANKLAND, F.R.S., IN THE CHAIR.

THE MICROSTRUCTURE OF BRASS.

BY O. F. HUDSON, A.R.C.S.

(Lecturer in Metallurgy in the University of Birmingham.)

The object of this paper is to give an explanation of the microscopic structure of the copper-zinc alloys with more than 50 per cent. of copper, in the light of a recently-published research on "The Constitution of the Copper-Zinc Alloys," by E. S. Shepherd (Journal of Physical Chemistry, June, 1904). In 1904, Mr. G. D. Ricketts and the author projected and commenced a research on this subject on lines similar to those adopted by Shepherd, and although much of the proposed research was abandoned on Shepherd's paper coming to our notice, the microstructure of the brasses has been carefully examined and our results compared with those of Shepherd. Shepherd gives a complete equilibrium curve for the whole series of copper-zinc alloys. This curve agrees in the main with that published by Roberts-Austen in the 4th Report of the Alloys Research Committee in 1897. Shepherd, however, considers there is no evidence in support of the view held by many workers that copper and zinc combine to form definite chemical compounds, and states that the six solid phases indicated by the equilibrium curve are all solid solutions of copper and zinc.

Referring to Shepherd's curve (Fig. 1), it is seen that

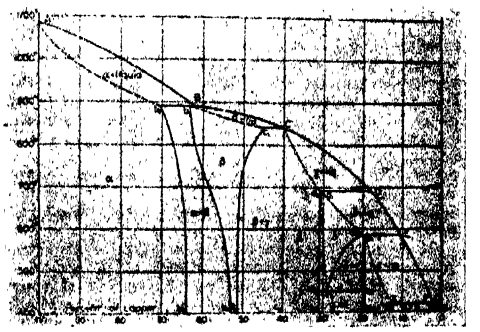

FIG. 1.

Equilibrium curve of zinc-copper alloys
(E. S. Shepherd, Journal of Physical Chemistry, June, 1904.)

for the range of composition of the alloys to be considered we have only to deal with three of these phases, which are distinguished as α, β, and γ, and whose limits of concentration vary with the temperature as indicated. It will also be seen that the alloys composed of one or two of these three phases may be divided into six groups, as follows:—

I. Alloys containing 71—100 per cent. copper, consisting entirely of α at all temperatures.

II. Alloys containing 64—71 per cent copper, consisting of only α at 400° C. and below, but composed of α and β at some higher temperature.

III. Alloys containing 63—64 per cent. copper consisting of mixed α and β at all temperatures.

IV. Alloys containing 53·5—63 per cent. copper, consisting of mixed α and β at low temperatures, and only β at some higher temperature.

V. Alloys containing 51—53·5 per cent. copper, consisting entirely of β at all temperatures.

VI. Alloys containing 40—51 per cent. copper, consisting of mixed β and γ at low temperatures, and only β at higher temperatures.

The microstructure of each of these groups will now be considered:—

I. Brass containing 71 per cent. copper or more, independently of the rate of cooling, consists of only one constituent, α, a solid solution of zinc in copper. The microstructure varies, however, according to the treatment the alloy has received. The ordinary cast metal, *i.e.*, moderately quickly cooled, has a well marked dendritic structure (Fig. 2), due to the non-homogeneous nature of the crystals: the solid which first solidifies is richer in copper than the still molten alloy, and the cooling is too rapid to allow diffusion to give complete uniformity. Annealing the cast metal allows diffusion to take place so that the crystals become quite homogeneous, and the structure is the usual polygonal one associated with a material consisting only of one homogeneous constituent (cf. pure metals) (Fig. 3). When the cast metal is rolled the original crystalline structure is broken down and becomes more or less finely granular. Annealing the rolled brass causes a regrowth of the crystals, with complete uniformity of composition as in the case of the unworked material after annealing, but with this difference that the

majority of the crystals show pronounced twinning (Fig. 4). The twinning of the crystals of α is characteristic of that constituent when annealed after straining; indeed, a specimen of cast brass that has been merely strongly gripped in the vice will show abundant twinning on annealing.

On cooling alloys of the second group (64—71 per cent. copper), crystals of α first separate until the temperature and composition reach B (of Shepherd's curve) when the still molten portion solidifies and splits up into a mixture of α and β (Figs. 5 and 6). During very slow cooling the β is redissolved by the α first formed and the brass consists entirely of α. The structure of the cast alloy, although resembling the cast structure of brass of the first group, usually shows the presence of a small amount of β (Figs. 7 and 8). The annealed structure is also similar, provided the annealing temperature is not above the line b_2b_3. Annealing above this point leads to the separation of β, which is not reabsorbed unless the cooling is very slow. This fact, as Shepherd points out, may have some bearing upon the question of the burning of brass: annealing should be conducted at a temperature well below the line b_2b_3.

The alloys of Group III. (63—64 per cent. copper) consist of a mixture of α and β, however cooled or annealed, and the structure resembles those of alloys in the next group.

Alloys containing between 53·5 and 63 per cent. copper, on first solidifying, consist entirely of β, which, on cooling, changes in composition, the excess of copper giving rise to a separation of α (Fig. 9). The cast alloy consists of a mixture of α and β (Fig. 10), and on annealing at temperatures above the line b_1b_1, the α is redissolved in the β. If the alloy be now quickly cooled, it will be seen to consist only of β (cf. Fig. 12).

The alloys of Group V., containing 51—53·5 per cent. copper, consist, however cooled, only of β. β differs from α in showing no dendritic structure in the cast state and no twinning on annealing (Figs. 11 and 12). Shepherd describes it as being of a more reddish colour than α with high percentages of zinc, and attributes the return of the red colour in brasses to this fact.

Group VI.—With less than 51 per cent. copper the third constituent γ first makes its appearance. It is white and exceedingly brittle and separates as an envelope to the β crystals (Fig. 14) (also in the form of secondary crystals in the β crystals), with the result that alloys with more than 49 per cent. zinc are very fragile.

All the specimens from which these photographs were taken were etched by gently rubbing on parchment moistened with dilute ammonia.

The letters, V and O, after the numbers, representing the magnifications, indicate vertical and oblique illumination respectively.

Discussion.

Mr. H. Silvester asked if it was possible to detect accurately by means of the microscope whether the metal had been burnt or not.

Mr. Rosenhain said it was pointed out some years ago by Prof. Ewing and himself that the existence of twin crystals in cast metals of the copper type—*i.e.*, metals consisting of copper or a solid solution of zinc or tin or any other substance in copper, never showed twin crystals in the cast state, but that they developed them as the immediate effect of a strain. The twin crystals were not, therefore, at any rate not entirely, the product of the annealing, as one would have gathered from Mr. Hudson's remarks, but were already formed mechanically from the deformation. It was probable that they were formed to a still greater extent, and probably still more clearly defined after annealing, but it was really the strain that set up twinning. Probably if Mr. Hudson had examined the strained metal before annealing, he would have found the twinning in it already.

Mr. A. T. Cocking asked if Mr. Hudson had considered the influence of time and temperature in the annealing upon the structures. In the course of several hundreds of micro-photographs of brass in varying conditions, taken during the last year, he had prepared a very complete diagram, showing the cycle of changes in the structure of the metal as it passed from the cast state to the rolled state, and then through the varying crystalline structures induced by the progressive annealing, until the metal was brought back again to the melted state; a very striking point in the series was the complete change in appearance not only in the regularity of the structure, but also of the individual crystals, by a very slight alteration in the time of annealing, and also by a slight alteration in the temperature employed. Varying the time in periods of five minutes and the temperature in 10°, and, taking the mechanical tests of a strip of metal at each period and each temperature, a very striking record was obtained. It showed a uniformity of better work at 15 minutes' duration at each alteration of temperature of the annealing throughout the whole system. At that time, the size of the crystal was correct, and there was a uniformity in the crystals which was not apparent at other times. Then the twinning of the crystals was seen to perfection. As the temperature was increased beyond the period which gave the best tests, the uniformity decreased until a temperature of about 850° was reached, when the spots, so very well illustrated on one of the diagrams referred to as showing the twinning of the crystals, were produced. A gradual increase in the temperature beyond that point caused the spots to gradually develop into the dendritic form of structure, which marks the original or cast structure, and so completes the cycle, commencing and terminating with the ordinary cast structure. A great deal in the appearance depended upon the way in which the light struck the plate of crystals under the microscope, and so much depended upon the way in which the metal had been etched. The best method of etching the surface for high power work was to use a solution of ammonia in hydrogen peroxide solution; the photographs then came out like engravings, if carefully taken; that was the only way in which consistent photographs of the same object could be obtained. He was inclined to think that some of the crystals which Mr. Hudson referred to and described as due to "twinning" were rather due to the "slipping" of one large crystal, which broke by a slight strain upon it. If more work were done upon that individual crystal, it would probably be found to be a mass of very tiny layers, a few of which etched out from the others. Probably Mr. Hudson would have observed that same fact for himself. He had never gone so far as Mr. Hudson to recognise in these photographs the actual individual eutectics, so much variation was due to the way in which the lights met the surface, and to the action of various etching solutions. Had Mr. Hudson found that difficulty and examined the same structure etched by different solutions?

Prof. Turner wrote, "No doubt the more we know of the internal structure and physical properties of the zinc-copper series, the more regular and uniform would be the material which was produced. This is particularly so in respect of sheet brass, and other similar material which has to be frequently annealed during its preparation. The work of Shepherd appears to be the most important, and the most revolutionary, which has appeared for a number of years, though numerous observers have worked on brass. Among these, Charpy calls for special recognition. It should be mentioned that, in preparing these alloys, the purest obtainable electrolytic copper and distilled zinc were employed, and every care taken to ensure that the alloys were really as represented. It is interesting to find that in so far as the two series of researches had covered the same ground, the observations of Mr. Hudson supported and confirmed the suggestions of Shepherd.

"This work would entail a revision of our conceptions of the constitution of brass. It would not, of course, in any way invalidate the facts observed by Laurie and others; but instead of explaining these results as being due to definite compounds which are formed with certain proportions of the constituent metals, we shall have to explain the changes in melting point, in electro-motive force, and in other physical properties as being due to the appearance or the preponderance of one or other of the solid solutions of zinc in copper, or of copper in zinc, which have been described by Shepherd."

Mr. L. Archbutt asked how the surfaces were prepared. He presumed all the slides were etched. How were they etched? There was not a really satisfactory way of etching these alloys of copper. He generally used for copper and its alloys dilute ammonia containing a few drops of peroxide of hydrogen, but the results were not satisfactory. One speaker referred to the importance of the time as well as the temperature in annealing. That was a matter of great importance. Had Mr. Hudson ever found, after annealing, it made any difference whether the specimen was quenched in cold water or allowed to cool naturally? He asked that question, because he made an observation lately which led him to think it did make a difference in the structure of the metal. He had heated small pieces of copper in a muffle and gradually increased the temperature with the object of ascertaining the effect it had on the growth of the crystals. The piece of copper had been heated to a temperature of about 1100°, just over the melting point. As soon as it was brought out of the muffle it re-calesced quite vividly. No doubt the copper had melted in the skin of oxide without changing its shape, and immediately solidified on removing from the muffle. The structure showed quite clearly that was the case, and that some of the oxide dissolved in the copper. He had obtained a beautiful specimen, accidentally, in that way.

Mr. Hudson said that burnt brass was characterised by a coarse crystalline structure, and frequently by the presence of small holes like bubbles of gas. With regard to the twinning referred to by Mr. Rosenhain, the effect of straining cast brass was made evident under the microscope by many series of parallel lines which he took to be slip bands; although the twinning was developed by the straining, it was made evident by annealing. Also, when very severely strained, the crystals were distorted and broken up, and, on annealing, recrystallisation took place with very obvious twinning. In reply to the question as to the relative importance of time and temperature in giving the best results in annealing brass, he could not speak from much personal experience, but he should say that, provided the temperature was not high enough to produce burning, a short annealing at a high temperature should give similar results to a longer annealing at a lower temperature. He had never noticed more than one constituent in brass containing over 70 per cent. of copper. The method of etching adopted, which was that of gently rubbing the specimen on parchment moistened with a diluted solution of ammonia, gave very good results, although the colours of the constituents of the etched sections as seen under the microscope might not always be the true ones. Thus the constituent β under these conditions appeared greenish-yellow in colour, although on a freshly filed surface it had a distinctly reddish tinge.

A RECORDING CALORIMETER FOR GAS.

THE RELATION OF FLAME TEMPERATURE TO CALORIFIC POWER.

BY J. WATSON BAIN, B.A.Sc. AND J. W. BATTEN.

The work which gave the experimental data of this paper was first suggested by the need of a recording calorimeter in the larger gas works. Undoubtedly before long cities will require the maintenance of a minimum calorific value rather than a minimum candle power as at present; hence a method of automatically and constantly registering the calorific power may soon become an urgent necessity. The relation between the number of heat units in a gas and the temperature of the flame produced when burned seemed to offer a solution of the problem.

At the outset it was recognised that both the flame temperature and the calorific power were dependent, fundamentally, on the composition of the gas, *e.g.*, an increase in the percentage of carbon dioxide or nitrogen would decrease both. It was also recognised that the temperature of the flame varied very materially, depending upon the relative point in the flame.

The apparatus used for finding flame temperatures consisted essentially in a Le Chatelier thermo-junction, previously calibrated for the melting points of pure tin, lead, zinc and aluminium, which was placed in an iron sheath, and thus exposed to the flame. The two wires leading from it were attached to a galvanometer reading directly in degrees centigrade.

The gas was burned in a small asbestos house (to prevent draughts upon the flame) having a hole in the side at the proper height to admit the thermocouple. Calorific power was measured by an ordinary Junker's calorimeter: from whatever source, the gas was drawn off and branched, one part going to the calorimeter and the other to the burner.

For the establishment of a relation it was found advisable to obtain a gas whose calorific power could be varied at will. For that purpose a gasolene gas was made by using a water blast, passing the air through a calcium chloride tower, then through a small reservoir of gasolene, and finally to the burners, after passing a tower filled with cotton wool, to prevent any possibility of the flame striking back to the gasolene.

Galvanometer readings and calorimetric determinations were made every three minutes and plotted, the result being as shown in Fig. 1.

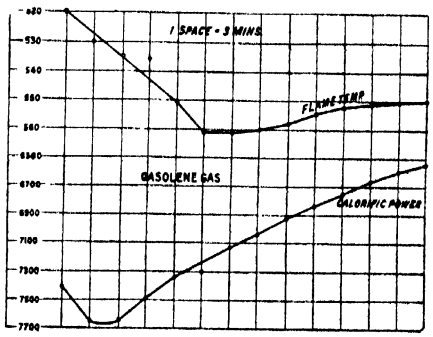

FIG 1.

It will be noted that there is a lag of about 18 minutes of the flame temperature behind the calorific power, due to the presence of the iron tube. This lag was also verified by several successive experiments. In order to overcome this a thick paste was made of powdered silica, fireclay and soluble glass, and placed around the

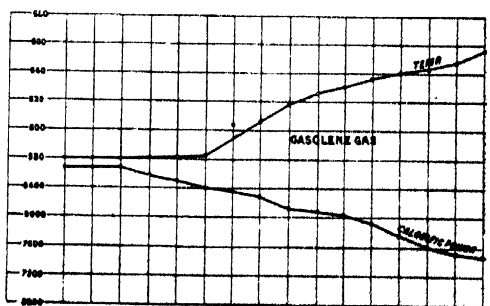

FIG 2

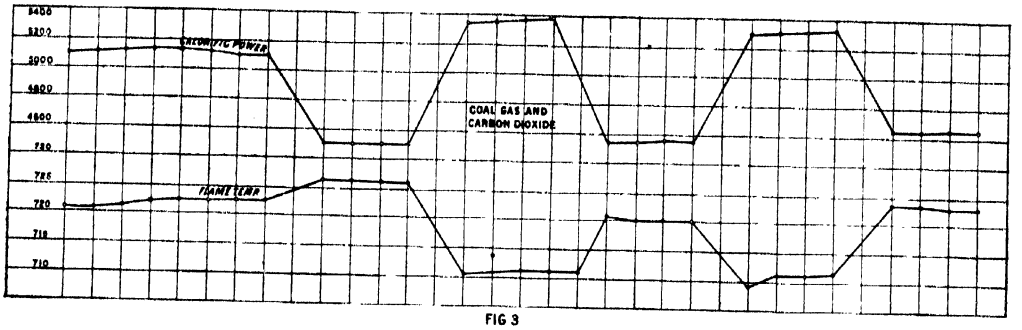

FIG 3

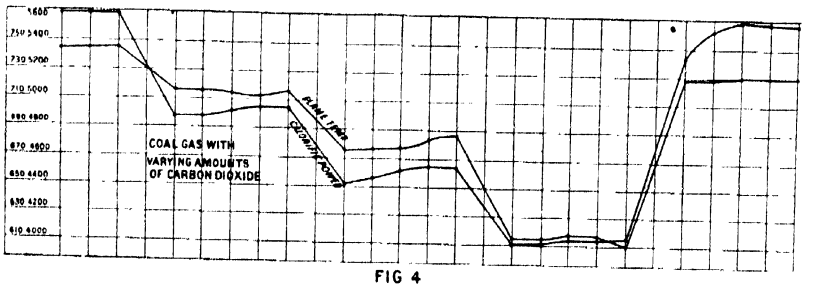

FIG 4

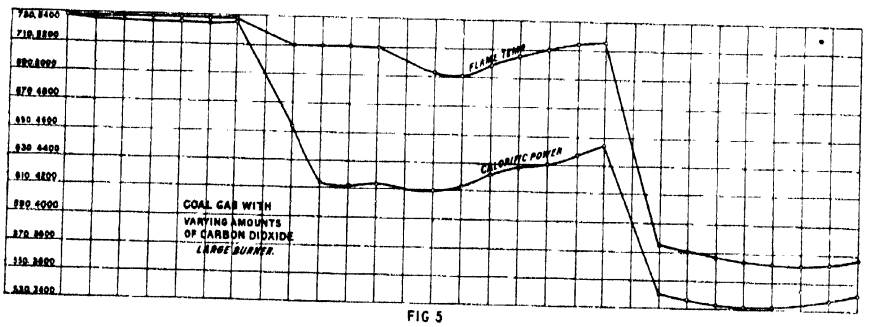

FIG 5

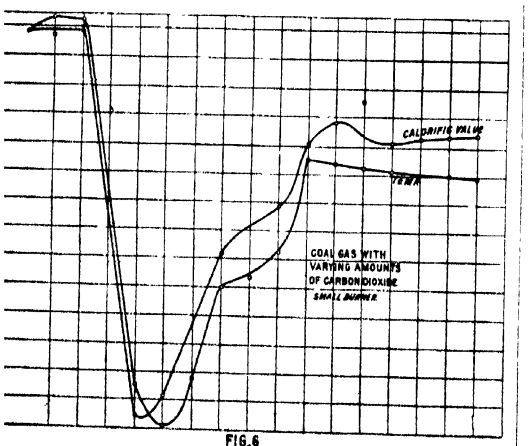

FIG. 6

junction. This was then rapidly calcined and used in the succeeding trials.

The first curve obtained (Fig. 2), here submitted, shows a relation between the two, but the reverse of what one would expect; the calorific power falls while the temperature rises. It is evident that this is possible if the thermo-junction is placed at first within the inner cone and then the flame shortened. In that case the calorific value would decrease while the galvanometer would show an increasing temperature.

For various reasons, the chief being that coal gas is the one most used in practice, the gasolene gas was replaced by it, and diluted by carbon dioxide obtained from a cylinder, to which a reducing valve was attached, to bring it in contact with the coal gas at low pressure. The peculiarity noted above is clearly shown in Fig. 3.

The position of the thermo-junction was then raised to a point higher than the top of the flame at any time, and Fig. 4 produced, which shows a fairly good conformation of the one curve with the other.

The next curve (Fig. 5) shows a similar conformation in general, though the relative falling off and increase in both varies widely at different times.

Curve 6 was made using a smaller burner, and indicates

a maximum variation of flame temperature from calorific power of about 2 per cent., an error which might quite readily be made in reading the calorimeter.

It will be noted in Fig. 5 that at A the fall of flame-temperature is much less comparatively than that of calorific power, while at B, the reverse is the case.

Evidently for a calorific value slightly less than that shown at B, we would have a position where both decrease at equal rates.

The net conclusion then is that there is undoubtedly a direct relation of flame-temperature to calorific value. It is impossible to keep the pyrometer always in the same relative position, but for a given burner, with a given amount of air supply, and for a gas varying in calorific power between certain fairly wide limits, a position may be found for the pyrometer, such that the relation between flame-temperature and calorific value will be a simple one.

In any particular case the whole apparatus would require before use calibration against a calorimeter.

MR. A. G. SALAMON IN THE CHAIR.

NOTES ON THE GUTZEIT TEST FOR ARSENIC.

BY J. A. GOODE AND F. M. PERKIN, PH.D.

Having been engaged for some months past in testing the electrolytic and other methods for arsenic analysis, we undertook a long series of experiments in order to ascertain whether it might be possible to render the Gutzeit test absolutely quantitative, and to see whether it might be possible to prepare standards which were quite permanent or at least as permanent as the standard mirrors employed in the Marsh-Berzelius method.

The chief objection to the Gutzeit method is the difficulty, or one should say the impossibility, of preparing standards which are permanent. Recently T. F. Harvey* suggested painting standards to match the stain produced by given quantities of arsenic and using the series thus prepared as a standard. We have not heard whether the idea has been adopted by other authorities and we have not tried it ourselves. There seems no obvious objection to this method, except the difficulty in first matching the tints, and it would be of interest if some firm would place such a standard on the market, as it is only by continued trials by different observers that the applicability of such a method can be proved.

Before trying to obtain permanent standards, we tested various methods for evolving hydrogen from zinc and other metals in order to see which would be the most sensitive. Our first endeavour was to obtain materials which were free from arsenic or were, at any rate, readily freed from it, so that a blank could be easily obtained. In the first place, we tried magnesium, which being a metal manufactured by the electrolysis of its fused chloride, should be free from arsenic, and on trial we found this to be the case. Now magnesium is a metal which is acted upon with great vigour by acids, and therefore it is rather difficult to keep the reaction within bounds. Even with N/1 sulphuric or hydrochloric acid the evolution of the gas is extremely violent, and is only modified to a slight extent by placing the flask in which the reaction is taking place in a basin of cold water. Owing to this fact, magnesium is not a very satisfactory metal to use in acid solutions. It then occurred to us to use ammonium salts as magnesium reacts readily with solutions of these salts according to the equation,

$$Mg + 2NH_4^{\cdot} = Mg^{\cdot\cdot} + 2NH_3 + H_2.$$

* Chemist and Druggist, 1905, 168.

Although magnesium reacts with all ammonium salts, therefore the equation has been expressed ionically—the best results were obtained by employing the chloride. That is to say, we found that from the all-important point of sensitiveness better results were obtained with ammonium chloride than with other salts of ammonium. Even with ammonium salts, unless care is taken, the reaction becomes much too vigorous, but there is no difficulty in keeping it in bounds by placing the apparatus in cold water when a steady and constant evolution of hydrogen takes place.

In our first experiments we used for generating the gas a Schroetter carbon dioxide apparatus, and with this we got excellent results. The wash tube which in carbon dioxide determinations contains concentrated sulphuric acid, contained in our experiments a solution of cuprous chloride (acid or ammoniacal) or a solution of lead acetate, to keep back traces of phosphine or hydrogen sulphide.

In carrying out the experiment, the ammonium chloride (about 5 grms.) was first placed in the apparatus and then about 1—2 grms. of magnesium turnings, wire or ribbon added, with magnesium powder the reaction is inclined to be too vigorous. The side stopper was then put in and about 10 c.c. of water run on to the mixture. The apparatus was gently shaken and then placed in a basin of cold water. As soon as an even evolution of gas was obtained—about one to two bubbles to the second—a piece of filter paper, previously soaked in a strong alcoholic solution of mercuric chloride and dried, was fixed over the outlet tube, and held in position with a rubber band, or by placing a glass tube slightly wider than the outlet tube over it. If at the end of 30 minutes a blank was obtained, then the required amount of arsenic was added. Working in this way there is no difficulty in showing the presence of 0·002 mgrm. of arsenious oxide, in fact, 0·001 mgrm. gives a marked stain. The evolution of the hydrogen gas should be checked at the commencement of the experiment, because it is difficult to control it should the action once get too vigorous.

There is one objection to the Schroetter apparatus, it is rather too small. We originally employed it because we did not wish to design a new apparatus which no one would buy, and because it is to be obtained in every laboratory. We now, however, use the apparatus depicted in Fig. 1, which, if not to be obtained in every laboratory, at any rate is readily made up from materials present in every laboratory.

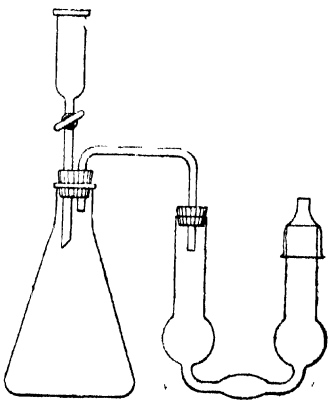

FIG. 1.

It consists of a conical flask of Jena glass, having a capacity of 250 c.c. and fitted with a dropping funnel for adding the solutions, also with a tube connected with a U-tube containing a 10 per cent. solution of acid cuprous chloride. The paper is held in position on the U-tube by means of a glass tube slightly wider than the U-tube itself. The cuprous chloride is to retain any sulphuretted hydrogen and some other gas which also, when magnesium

is used, causes a stain on the mercuric chloride paper. At first we thought that this gas was acetylene (we, therefore, then used ammoniacal cuprous chloride) produced from a trace of carbon in the magnesium, and on putting a little calcium carbide into the apparatus and running in water we found that the paper was likewise stained. In order to make certain, however, whether this gas was due to acetylene, pure acetylene was prepared by acting upon copper acetylide with hydrochloric acid, and it was then found that the pure gas, so obtained, had no action upon mercuric chloride. We found, further, that the compound obtained by passing pure acetylene into a solution of mercuric chloride is white. Furthermore, there is no stain produced when the gas is passed through an acid solution of cuprous chloride. But if cuprous chloride is not employed, and if the evolution of gas becomes too vigorous—when magnesium and ammonium chloride is used—it is impossible to obtain a blank, because a black or yellowish black stain is invariably obtained. The odour of the gas in these circumstances is similar to that produced when dilute sulphuric acid acts upon iron.

It ought at this place to be mentioned that we did not find it possible to completely arrest phosphine with cuprous chloride. On the other hand, Dowzard* states that phosphoretted hydrogen is completely absorbed by cuprous chloride, although further on in the same paper he says, "if phosphites or hypophosphites are present, the sample should be treated with bromine before examination," the bromine, of course, oxidising to phosphates, which are not reduced under the conditions of the experiment. If the cuprous chloride solution is concentrated, it does indeed prevent the phosphine passing forward, but it also prevents the arsenic hydride. Knowing that phosphine forms compounds with stannic chloride, aluminium chloride and antimony pentachloride, we tried passing the gas through solutions of stannic chloride in hydrochloric acid, but the phosphine passed through as before. Pure liquid stannic chloride appears to stop it, but, owing to the unpleasant character of this liquid, it is obviously out of the question to employ it. A tube packed with anhydrous aluminium chloride also failed to hold back the phosphine. Therefore, when readily reducible, phosphorous compounds such as hypophosphites or phosphites are being dealt with, the only thing to be done is to oxidise the solution with a little bromine. This also oxidises arsenites to arsenates, and then the arsenic determination should be carried on for about 15 minutes longer. Or else, if the gas is to be generated with zinc and acid, the arsenate may be reduced by the addition of stannous chloride as recommended by Hill and Collins.†

It is a point worthy of note that the yellow colour produced by the arsenic hydride on the mercuric chloride paper is turned black by the addition of ammonia; in fact, when the yellow stain is so slight as to be hardly distinguishable, the addition of ammonia will cause quite a marked black stain. This points to the reduction of the mercuric salt to the mercurous condition, Lohmann‡ gives the formula of the yellow compound as $As(HgCl)_3$, from which one would get the equation:

$$AsH_3 + 3HgCl_2 = As(HgCl)_3 + 3HCl.$$

We hoped at one time to be able to use this as a method for determining the quantities of arsenic, but owing to the difficulty of judging between different intensities of black stains we had to give it up. The black stain also is fugitive like the yellow one. The only advantage which it has over the yellow stain is that it enables one to work at night; because it is often impossible to see slight yellow stains by artificial light, but there is no difficulty in recognising a black one.

It has already been stated that there is no difficulty in distinguishing $\frac{1}{1000}$ mgrm. of arsenious oxide when magnesium and ammonium chloride is used. Parallel experiments with zinc and sulphuric or hydrochloric acid show that zinc and acid is slightly more sensitive than magnesium with ammonium salts, because with zinc and acids it is possible to estimate $\frac{1}{2000}$ mgrm. with a mercuric bromide paper. Chapman and Law* find that there is considerable difference in the sensitiveness of zinc, but that if the zinc is insensitive the addition of small quantities of a pure cadmium, lead, or tin salt increases the sensitiveness. Experiments were, therefore, carried out to see whether the sensitiveness of the magnesium would be increased by means of the addition of cadmium salts. We found, however, that the addition of cadmium salts decreased the sensibility. In one experiment, for example, with magnesium and ammonium chloride, to which cadmium chloride had been added, we failed to obtain a stain with 0·002 mgrm. of arsenious oxide, but the stain was distinct with 0·005. It has already been pointed out that we can detect 0·001 mgrm. with pure magnesium and ammonium chloride.

With acid and zinc, 1 c.c. of a 10 per cent. solution of copper sulphate decreased the sensitiveness considerably, the same quantity of a 10 per cent. solution of iron was much less marked, nickel had almost the same effect as copper, and cadmium did not improve the sensibility. It is, therefore, advisable to have all foreign metals absent.

Chapman and Law measured the potential upon a potentiometer of the cells, zinc-sulphuric acid and zinc-cadmium-sulphuric acid against a hydrogen normal electrode and found the following numbers:—

Solution.	Metal	Potential.
Sulphuric acid	Zinc	1·398
" "	Zinc + cadmium (20 grms. $CdSO_4$)	1·419
" "	Zinc	1·403
" "	Zinc + cadmium (20 grms. $CdSO_4$)	1·372

It occurred to us that it would be interesting to measure the potential of the magnesium cell in a similar manner. The magnesium electrode consisted of a carefully cleaned ingot of the metal 1·5 cm. diameter and 7 cm. long. The volume of the solution in each case was 150 c.c., and to obtain the Mg/Cd electrode 5 c.c. of a 10 per cent. solution of cadmium sulphate was added. The potential of the hydrogen electrode was 1·065. The following numbers were obtained:—

Solution	Metal.	Potential.
$N/1$ NH_4Cl	Mg	1·854
$N/1$ NH_4Cl	Mg + Cd	1·664
$N/1$ HCl	Mg	1·932
$N/1$ HCl	Mg + Cd	1·684
$N/1$ H_2SO_4	Mg	1·993
$N/1$ H_2SO_4	Mg + Cd	1·570

If the potential of the electrode alone determines the reducing power of the metal, then it would follow from the numbers obtained that magnesium is a much more powerful reducing agent than zinc and that the addition of cadmium should render it less active. It will be noticed from the experiments of Chapman and Law that in one case they find that the addition of cadmium (when small quantities are added) increases the potential. But that in the other case (where large quantities are added) a decrease in potential is produced. Yet they find that when the zinc is insensitive it becomes more sensitive on the addition of cadmium. It should be pointed out that with magnesium the evolution of gas was exceedingly rapid, and this may perhaps to some extent account for the very high numbers obtained in our experiments. But still the lowering of potential on the addition of the cadmium salt is very great, especially in the case of the sulphuric acid solution; but even here the numbers obtained from the cadmium and magnesium are higher than with the zinc electrode alone.

When reducing with the electric current, if the substance to be reduced is a difficultly reducible one, endeavour is always made to work with an electrode which will allow of as high a super-tension (over potential)

* Chem. Soc., 1901, 715.

† Chem. and Drug., Sept., 1905.

‡ Pharm. Zeit., 1891, 748—756.

* Analyst, 1906.

as possible. For example, Tafel* found that with lead electrodes he could reduce uric acid, but that he failed when other electrodes were employed. Similarly Hackford and Sand† claim that by using lead electrodes they obtain a more thorough reduction of arsenic compounds than by using platinum electrodes. Our own experiments confirm this contention. We did not determine the potential or drop in potential produced by the addition of other metals We hope, however, to study the matter in detail at a future date. We might mention, however, that Chapman and Law, *loc. cit.*, found that platinum, cobalt, copper and iron all caused a drop in potential. Now all these metals retard reduction; therefore, magnesium, with its high potential, should be a much more powerful reducing agent than zinc. The potential of the electrode alone does not seem to be the only factor which determines the reduction. Before the matter can be thoroughly understood probably a great deal more experimental work will be necessary.

Too much weight must not be placed on the potential numbers obtained, which it must be remembered are not super-tension numbers, but the solution tension of the metals.

Probably the explanation of the lowering of the potential of the magnesium on the addition of cadmium salts, is to be found in the behaviour of magnesium with solutions of cadmium salts. When magnesium is added to a solution of cadmium sulphate or chloride, a vigorous evolution of hydrogen ensues and metallic cadmium is thrown out. Probably the cause of this evolution of hydrogen is due to the tendency of magnesium salts to hydrolyse. The first reaction will be the replacement of the cadmium and formation of a magnesium salt, the magnesium salt will then be hydrolysed and a basic salt be produced. This is, we think, proved by the following example. If powdered magnesium is added to a neutral solution of magnesium chloride or sulphate a very vigorous reaction ensues, hydrogen is evolved and a basic salt separates out :—

$$Mg + MgSO_4 + 2H_2O = \begin{matrix} Mg\langle OH \\ Mg\langle OH \end{matrix} SO_4 + H_2.$$

The reaction between cadmium salts and magnesium can thus be represented :

(*a*) $Mg + CdSO_4 = Cd + MgSO_4$.
(*b*) $Mg + MgSO_4 + 2HOH = Mg_2SO_4(OH)_2 + H_2$.

Experiments were also made with aluminium both in alkaline and acid solution, the strength of the solution in each case being 4N. It was found, however, that when the reduction was carried out with aluminium that even with $\frac{1}{250}$ mgrm. of arsenious oxide no stain was obtained, therefore no further experiments were carried out with this metal.

Not having succeeded in obtaining stains which were permanent on keeping, we turned our attention to the formation of the stain itself. It occurred to us that it might be possible to employ some other substance than mercuric chloride. Silver appears to be out of the question for reasons given by August Gotthelf‡; also because, as Dr. Tilden pointed out when discussing the paper of Chapman and Law, *loc. cit.*, silver nitrate is reduced by molecular hydrogen.

Paper soaked in hydrogen aurichloride was tried and intense pink or purple stains were obtained. We found, however, that it was practically impossible to obtain a blank. Also, the paper soaked in the gold solution very soon became purple on keeping, the mere fact of drying it in the steam oven was often sufficient to turn the paper a purple colour. But we found that by preparing a $\frac{1}{2}$ per cent. solution of hydrogen aurichloride in absolute alcohol, soaking the paper in this solution, pressing it between dry filter paper to take out the excess of solution and drying in the steam oven for from five to 10 minutes, that the paper was much more permanent. If this paper was employed at once it was possible to obtain a blank, but after keeping for a few hours it was no longer reliable. The stains obtained, after washing with hydrochloric acid, are quite permanent, but the method, unfortunately, is much too unreliable to be of any use. Platinum salts are not reduced with relatively large quantities of arsenic. Vanadium salts are not reduced, although acid solutions of vanadium give a magnificent blue on reduction with sulphur dioxide.

We then tried paper soaked in a strong alcoholic solution of mercuric bromide. In this case, although the stain produced is not permanent, it is more intense than when mercuric chloride is employed and, therefore, the test is more delicate. After the stain has been obtained the paper is placed on a watch glass and moistened with a few drops of concentrated hydrochloric acid, as recommended by Bird* for mercuric chloride papers. The watch glass is then warmed for a minute, and the acid poured off. The paper is then washed with a little water and slipped off the glass on to a clean piece of white paper, where it is allowed to dry. Care must be taken not to add too much acid or to heat too long, or else this stain will become fainter and can be made to disappear completely. But by careful treatment with hydrochloric acid, stains become visible which could be hardly seen without it. By using the mercuric bromide paper $\frac{1}{2000}$ mgrm. of arsenious oxide is quite readily recognised. The papers used for soaking the mercuric salt were smooth English filter papers. The diameter of the paper in contact with the gas was 14—15 mm. The stain may be obtained in a more concentrated manner by placing a rubber stopper in the apparatus and fixing in a glass tube of 5 mm. internal diameter, as shown in Fig. 2. When dealing with very small quantities of arsenic, it is advisable to modify the apparatus in this manner. In fact we prefer this form of the apparatus rather than that shown in Fig. 1.

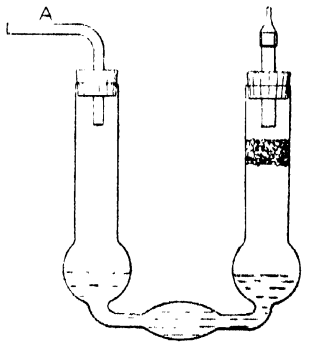

FIG. 2.

When experimenting on the permanency of the stain, we prepared little discs of plaster of Paris soaked in the mercuric salt, but although they showed the stain very well, we were unable to wash them with hydrochloric acid and it was a difficult matter to fix them on to the apparatus; we, therefore, came back to the paper discs.

For smoothness of working we prefer to use magnesium and ammonium chloride, because when once started the apparatus will go on gently evolving hydrogen for about two hours without further attention. With zinc and acids the reaction is sometimes rather intermittent. It is interesting to note the different appearance of the zinc in different experiments. Sometimes the whole solution becomes milky from the evolved gas. When this happens the action is generally the reverse of smooth and the gas comes off intermittently. At other times the individual pieces of zinc become of a spongy appearance from the hydrogen clinging on to them; when this is the case the reaction goes on smoothly and very little attention is required.

The time element is also of importance. Most observers

seem to consider that half-an-hour is sufficiently long for each determination. We find that it requires 45 minutes to drive out all the arsenic when 0·002 mgrm. is used, and therefore consider it better to take one hour to each determination and with arsenates 1½ hours. If the arsenic is not all got rid of in the Gutzeit apparatus when zinc and acid is used, it must follow that it is also *not* got rid of in the Marsh apparatus. This fact would not necessarily matter if all the tests were invariably carried out in the same time, because it is probable that $\frac{1}{100}$ mgrm. As_2O_3, for example, would always give the same intensity of mirror in, say, 30 minutes and, therefore, the estimations would be correct, as the comparison in each case would be the same. The same line of reasoning applies to the electrolytic method. With reference to the electrolytic method, we have found the apparatus of Hackford and Sand, or a modification of this, to give very satisfactory results for arsenites.

Now as to the reliability of the Gutzeit test. It is not possible to prepare permanent standards, therefore, all determinations must be done in parallel. The apparatus required is simple, there is no reason why one should not start four or five going at one time: one the actual determination and the others standard quantities. We found exactly the same quantities of arsenic in commercial samples of borax and cream of tartar, which had been examined on the Marsh apparatus, from an outside source. With reference to the different methods of detecting arsenic, the Marsh-Berzelius apparatus requires a lot of experience, but in the hands of an experienced manipulator may be said to be practically infallible. The same remarks apply to the electrolytic method when a lead cathode is used, although this is not quite so delicate as the Marsh-Berzelius apparatus. The Gutzeit test requires care and experience and then leaves little to be desired. In all the methods the samples to be tested should be as free as possible from foreign substances especially metallic impurities. For general testing purposes we think the Gutzeit test has decided advantages over the Marsh-Berzelius. But for cases of poisoning, of course, the Marsh-Berzelius is the apparatus which would be employed.

In conclusion, we may state that experiments are being made with the electrolytic apparatus and its applications to the Gutzeit method of testing—so far the results have been very satisfactory.

Discussion.

The Chairman said he hoped the discussion would trend in the direction of showing the value of this process as compared with the Marsh-Berzelius, its quantitative value and the accuracy and speed with which the determinations could be conducted, more particularly in reference to the complications which it appeared to him would be introduced by subsidiary reactions in respect of the material introduced to be tested, and the condition, acid or otherwise, in which that material was.

Dr. Divers said he had been much interested by the series of unsolved problems in inorganic chemistry contained in the first part of the paper. Certainly organic chemistry was now much easier to develop than inorganic chemistry.

Mr. A. C. Chapman said the paper appeared to resolve itself in the first place into a plea for the Gutzeit test, and in the second place into a criticism of some results obtained by Mr. Law and himself and set out in a paper, dealing with the reducing action of hydrogen, recently communicated to the Society of Public Analysts. The Gützeit test suffered from many serious disadvantages. In the first place, as the authors had pointed out, it was impossible to prepare standards which were in any way permanent. In the second place the stains were seriously affected by light and also by certain vapours which were frequently present in the laboratory atmosphere. In the third place—and this was perhaps one of the most important objections—it was not, strictly speaking, diagnostic of arsenic and did not yield results which were characteristic and definite. In the Marsh test an arsenic mirror was obtained from which arsenious oxide crystals could be prepared, and could be used for confirmatory purposes. In work which was so important as the estimation of traces of arsenic in food products, it seemed to him that that should be a *sine-qua-non* in any process employed, and in that respect the Gutzeit test laboured under a grave disadvantage. There was also the fact that hydrogen phosphide, hydrogen sulphide, and apparently some hydrocarbons which the authors had not been able to identify, also produced stains which were not easily distinguishable from those produced by arsenic. A final further objection was that it was impossible to assess the stains produced by artificial light. Bearing all these points in mind, it seemed to him that the time was far distant when the Gutzeit method could, save in a limited degree, replace the Marsh-Berzelius method for the estimation of traces of arsenic. Turning to the question of the relationship between the reducing efficiency of hydrogen and the source from which it was obtained, it seemed to him the authors' experiments in every way confirmed the conclusions he (the speaker) and Mr. Law had put forward. In the first place, if it were a fact that the potential of hydrogen obtained from magnesium was much higher than of that obtained from zinc or cadmium, it was only what might have been expected from Mr. Law's and his own results, that the addition of cadmium salts would reduce the potential and diminish the reducing activity, and that appeared to be the case. But he would go a good deal beyond that. As a matter of fact, the authors had not measured the potential of the hydrogen obtained in these experiments. They had merely measured the solution-tension of the magnesium in ammonium chloride solution, and, judging from the rate at which the gas came off in the experiments shown, the difference between the solution tension of the metal and the potential of the hydrogen must be very great indeed. In fact, the one magnitude only approached the other when the rate of hydrogen evolution was very small, as in the case of pure zinc or pure cadmium; so that the numbers put on the board really had little or no meaning as a criticism of their results. There really was no *a priori* reason for supposing that the introduction of cadmium into the flask in the magnesium experiment should either diminish or increase the reducing activity of the evolved hydrogen; or, which came to the same thing, that it should diminish or increase its potential. As a matter of fact they had no knowledge whatever of the potential of the hydrogen from magnesium dissolving in ammonium choride, but they had certain other information which lead them to suppose that magnesium, zinc and cadmium all stood somewhere near together with regard to hydrogen-potential, and that being so—it certainly was so with zinc and cadmium—whether cadmium increased the reducing activity of a sample of zinc or of magnesium would depend, in the first place, on the purity or impurity of the zinc and magnesium in question; and in the second place—and this was more important—on the way in which the cadmium was deposited on the surface. On neither of these points had the authors given any information at all. That being so, there was no reason why they should anticipate any particular result from the introduction of cadmium into the evolution flasks. One thing was pretty certain, and was supported by an immense number of his own experiments (because he had used cadmium in every Marsh experiment which he had made for many months), and this was that the potential of the hydrogen given off in the case of zinc depended very largely on whether one obtained a uniform coating of cadmium over the metal to be treated or whether it was deposited in an uneven and spongy form. In the experiments described, he thought the cadmium must have been deposited very unevenly. It was in fact a very difficult matter to obtain a uniform coating of cadmium over magnesium, but that really was one of the most important points in determining whether cadmium would produce an effect or not. The authors said that he and Mr. Law had recommended the use of cadmium for sensitising pure zinc, but that was what they had carefully refrained from doing. They only gave the results of their experiments, leaving chemists to draw their own conclusions. They made no recommendation

simply because there were some cases in which cadmium did not produce increased sensitiveness for reasons not yet ascertained, and they did not desire to mislead anybody working on this very intricate subject. As stated, however, in the paper he had referred to, the potential of hydrogen was one factor in reducing efficiency and an extremely important one, but they recognised that there must be other factors. They had also made experiments with aluminium, which went to confirm those of Dr. Perkin. Using it in the Marsh test they observed the formation of a white deposit in the combustion tube which they could not explain. Aluminium was apparently quite unfitted for use in the Marsh-Berzelius test. With regard to the quantities which had been mentioned, he thought the time had now come when what they had to do was to take as a minimum, say, 1/500 mgrm. and endeavour to find that with absolute certainty. It was far more important to work with certainty to 1/500th, which was surely as far as anyone could desire to go, than to sometimes be able to detect 1/2000 mgrm. He had recently been making experiments on the electrolytic method, using pure tin cathodes, and had got results which were rather encouraging. Reduction took place much more readily than with platinum, and tin was for several reasons not quite so difficult to work with as lead.

Mr. T. TYRER said the Gutzeit test was even now by no means perfect. He had made experiments with the stains, and it was interesting to hear that the bromide test was, on the whole, more precise as to colour. There was no doubt that the stain of arseniuretted hydrogen upon mercuric chloride paper was mercurous, which turned black on the addition of ammonia, but it was necessary to take various precautions and adopt suggestions which had been made by Messrs. Hill and Collins, Kirkby, Charles Tyrer and Bird, all with the definite object of absorbing interfering agents, and when these suggestions were combined, one was enabled to make comparisons about which no doubt could exist. While the stain of mercuric chloride was affected by light and age, it was undoubtedly blackened (and to that extent it was confirmatory) by ammonia; but the phosphoretted hydrogen stain, which could scarcely be seen even with known quantities of arsenic, was less affected, and the sulphuretted hydrogen stain was slightly affected; under these circumstances what was to be done? It was a question of comparison, with colours which were in themselves delicate and requiring considerable judgment to differentiate. He regretted that Dr. Perkin was not able to give a working illustration with magnesium, but the reactions exhibited were certainly surprising, and showed that there were certain points against which precaution ought to be taken. He had tried ammonium chloride with magnesium, but the rate of evolution of hydrogen depended not only on the state of division, but also on the concentration of the ammonium chloride solution. If this method were adopted for the evolution of the hydrogen, then the precautions would have to be increased. But the reaction was certainly worth considering, and working out to definite conclusions. From the appearance of the magnesium with magnesium chloride and sulphate, it was clear the reactions were scarcely so simple as described by the authors. Of course, in using ammonium chloride, provision must be made for absorbing the ammonia vapours evolved so copiously.

Mr. C. A. HILL said the use of stannous chloride had a distinct advantage, as it reduced arsenates to arsenites, and, therefore, made the test more completely comparative, and also because it made the evolution of gas steady and regular. It was usual to compare the stains obtained in any test with the stain obtained from a solution containing a known amount of arsenite. The presence of stannous chloride also reduced the time necessary for the operation. In his experiments, this time varied according to the condition in which the arsenic was present to start with, but he could confirm Dr. Perkin that in some cases it was necessary to run for an hour. The question of the fading of the standards was not so important as might appear, owing to the ease with which fresh standards were prepared. They usually prepared them two or three times a week. He congratulated Dr. Perkin on the use of bromide; he had found it at least four times as delicate as the mercuric chloride.

Mr. JULIAN L. BAKER asked how the authors would deal with a solution of organic compounds containing arsenic, such as an ordinary malt extract or sugar solution. The varying proportion of acid to be introduced into the ammonium chloride solution and magnesium would materially affect the rapidity of the flow of gas, and, consequently, the resulting stain; this would not be comparable with the four or five standards which were simultaneously being made.

Dr. L. T. THORNE said the difficulties in the way of the Gutzeit test were very great as a quantitative test. There was one other point which occurred to him during the reading of the paper, and that was the need for the further manipulation of the stain by means of hydrochloric acid or otherwise, to get it more fully shown up, and that the manipulation required very great care or it might affect the result. Dr. Perkin himself mentioned that if the hydrochloric acid was used too strong, or the heat was too much, the stain was reduced; so that his own feeling was that the Gutzeit test could not compare for accuracy, delicacy and reliability with the Marsh-Berzelius test as now carried out. With regard to the addition of cadmium to zinc to increase its activity, he should like to confirm the results given in Messrs. Chapman and Law's recent paper (Analyst, 1906, 3). He had been in the habit of using electrolytic zinc for a long time past and had very good results without any admixture, but a short time ago a new batch of electrolytic zinc came in, the sensitiveness of which was very much reduced. The electrolytic zinc was always purified by the sodium process and then gave very good results, but in the batch referred to, the sensitiveness, even after treatment with sodium, was not quite satisfactory. The effect of cadmium was tried. About 2 per cent. of cadmium metal was alloyed with the zinc, with the result that the sensitiveness was much increased, but at the same time traces of arsenic showed up, probably from the cadmium not being quite pure. The cadmiumised zinc was therefore submitted to the sodium process, and reacted even more readily to this sodium treatment than the zinc itself, and a cadmium-zinc was obtained which was perfectly free from arsenic, and which showed great sensitiveness and reliability. That was an interesting point, not only as confirming Chapman and Law's results, but also as showing that in an alloy, which was a very intimate mixture, the effect seemed almost more definite than where by using a cadmium salt in the Marsh apparatus only a deposit of cadmium was obtained on the surface of the zinc.

Mr. E. GRANT HOOPER said his experience had shown that there was a distinctly useful application of the Gutzeit test in a direction that had not been quite presented to the meeting. It was not so much in determinations of actual quantities of arsenic that the Gutzeit test was, in his opinion, most useful, but rather where it was required to show whether or not a minimum quantity was present in the substance under examination; and with reference to that he was rather surprised that no reference had been made to the work of the Pharmacopœia Special Committee, which had, under the direction of Professor Dunstan, to his mind, considerably improved the Gutzeit test in the way of systematising the procedure. In connection with one point which had been referred to by Dr. Perkin, the question of time; those familiar with this later pharmacopœia practice would remember that it was proposed the test should run for two hours, and that he thought was a distinct advantage. With reference to the fading effect, to which reference had been made as one of the difficulties connected with the test, he would suggest that in the application of the method, in the particular direction to which he had alluded, there was no real difficulty in setting three experiments going at the same time—one a blank, one with the standard minimum you were searching for, and one with the substance under examination. If the Gutzeit test were used in that way and under those conditions, systematised, as it had been in the report to which he had referred, then the Gutzeit test had distinct advantages and would be useful to many who had not the opportunity, and

probably were not inclined to devote the time necessary for an electrolytic determination.

Dr. F. B. Power said the Gutzeit test had been in more or less general use for a number of years, and he recalled particularly a very lengthy investigation of the subject by the late Prof. Flueckiger of Strasburg, which was published in the *Archiv der Pharmacie* in 1880. That investigation was principally confined to the sensitiveness of the test, and the conditions under which it could be most usefully carried out. Comparisons were instituted, especially between the Gutzeit and the Marsh-Berzelius test, and the author came to the conclusion that the former should be given the preference for the testing of medicinal chemicals. That gave an impulse at the time to the use of the test which was very marked, and which led to its general introduction for that specific purpose. It was of interest to observe the consideration given to it in the new *United States Pharmacopœia*, only recently issued, where two or three pages were devoted to the conditions for obtaining accurate results, especially with regard to the presence of hydrogen phosphide, hydrogen sulphide, &c. He was not quite prepared to agree with the opinions expressed by some of the preceding speakers, which were somewhat depreciatory of the test, because he thought it fulfilled a very important and useful purpose, especially for the detection of arsenic in medicinal chemicals, which required to be so frequently tested for this impurity.

Mr. H. D. Law wrote:—"The potential of hydrogen set free from metallic surfaces unquestionably plays a very important part in reduction processes. This has been amply demonstrated by Tafel in the case of refractory organic substances and later by Sand and Hackford, Chapman and Law for the oxides of arsenic. It is not the only force influencing these reactions, for in many cases catalysis becomes the determining factor. In the reduction of arsenious oxide this latter may be left out of consideration, for its action is only a subordinate one. The seemingly anomalous behaviour of cadmium surfaces observed by the authors needs, therefore, careful consideration, and certainly a more detailed study than has been given. The work set forth in the present paper in no way disproves the theory enunciated by Chapman and Law; on the contrary, most of the examples confirm the view already given. The measurement of the potential of magnesium is interesting, but throws no light on the nature of the hydrogen liberated from the metal. The figures given represent the solution tension of magnesium, which is considerably higher than the potential of the hydrogen set free, as may be inferred from the very energetic reaction taking place. The solution tension of a metal can approach the potential of the hydrogen formed in the metallic surface only when a very moderate action is taking place. On the addition of a salt of cadmium, this latter metal becomes deposited in the magnesium and partially covers it. The solution tension is then lowered somewhat and the super-tension of the hydrogen is increased. Consequently, the reaction is less energetic and the figures given are nearer the actual potential of the hydrogen. The figures given by Chapman and Law also do not represent the true potential of the hydrogen, but the approximation is very close, for the action was only slight. The authors have found that the addition of cadmium chloride to the Gutzeit apparatus in no way increases the sensitiveness of the magnesium used—on the contrary, a brisk reaction takes place with a solution of cadmium chloride without any addition of ammonium chloride. This is undoubtedly due to the formation of magnesium chloride. The magnesium chloride is hydrolysed by water setting free hydrochloric acid, which in turn attacks the magnesium to form hydrogen. This hydrogen prevents the formation of metallic cadmium in a compact mass round the magnesium, but causes the deposited metal to break away. The action of cadmium sulphate on magnesium is, however, very slight, and in this case the cadmium completely covers the surface of the magnesium. If now ammonium chloride is added, hardly any action takes place at all, due chiefly to the increased super-tension of the hydrogen, but also to the diminished solution tension of the metal. It will, however, reduce arsenious oxide to the hydride. The solution of this problem is still very incomplete and until more work is done it is quite impossible to predict results. The action of salts of iron, nickel and copper clearly show the influence of super-tension on the sensitiveness of the source of the hydrogen, confirming the experiments already published by Chapman and Law. The authors have succeeded in considerably improving the Gutzeit method of estimating arsenic. In their hands, this method has become equal in sensitiveness to that of Marsh-Berzelius, and no more difficult to manipulate. The greatest disadvantage to its use is the impossibility of preserving the standards. When this difficulty has been overcome there is no reason why this method should not be adopted in preference to the one now generally used for accurate determinations of arsenic."

Dr. Perkin, in reply, said the discussion showed rather a tendency to take sides, as if it were the Marsh-Berzelius *v.* the Gutzeit. They had not taken any side, they approached the subject with an absolutely open mind and did so by accident. As a matter of fact, they were working with various electrolytic methods, and it so happened that someone wanted to carry out the Gutzeit method. The results obtained were not very comparable, and, therefore, the matter was taken up and investigated simply to get more knowledge of the subject. Speaking, generally, they thought that for a method of general applicability to discover whether a given substance contained arsenic in which a minimum was allowed, or a given quantity of arsenic, the Gutzeit test was preferable to the Marsh-Berzelius. Their own practice in making an estimation was to run three in parallel—one a blank, one with a given quantity, and the other the substance to be tested, and if necessary they could put another one with another quantity if they wished to know exactly the amount. Stains, if kept in the dark, would last for two or three days quite well. Mr. Bird gave the time for the test as half-an-hour, and possibly with a boiling solution that might be sufficient, but under ordinary conditions it was not. It did not matter when one was always doing something else, if the apparatus was running for one hour or more, though he did not consider two hours was necessary. The hydrochloric acid treatment of the paper was taken from Mr. Bird, who first suggested it. They certainly did not go quite so far as he did in actually getting arsenic from it but they found the stain much more permanent, and it was easier to determine the exact amount if they treated it first of all with hydrochloric acid.

With reference to Mr. Baker's question, it would be necessary to neutralise with ammonia if the substances were to be tested in an apparatus containing an ammonium salt. They had chiefly experimented with inorganic substances containing arsenic. Glycerine did not interfere, but probably it would be necessary to get rid of mucilaginous substances before applying the test.

THE SEPARATION OF BRUCINE AND STRYCHNINE—INFLUENCE OF NITROUS ACID IN OXIDATION BY NITRIC ACID.

BY WILLIAM COLEBROOK REYNOLDS, B.SC., A.R.C.S., AND ROBERT SUTCLIFFE.

When nitric acid, under suitable conditions, acts on a mixture of strychnine and brucine, the brucine is decomposed into non-basic, strongly coloured constituents, and the strychnine remains almost unacted upon, and hence the amount of each present can be determined. The method is more accurate, and occupies much less time, than older methods, such as the ferrocyanide process, and has rapidly replaced them.

The first proposal to use nitric acid for the separation of brucine from strychnine, came from Keller (Zeits. Osterr. Apoth. Ver., 1893, 542). His method consisted in adding, to the solution of 0·2—0·4 grm. of the mixed

alkaloids in 10 per cent. H_2SO_4, 1 c.c. of nitric acid of sp. gr. 1·42, allowing the reaction to proceed for from one to one and a half hours, then making the solution alkaline with ammonia and shaking out with a weighed quantity of a mixture of chloroform and ether, of which a weighed quantity was then distilled.

This process was examined by Stoeder in 1899 (Ned. Tydschr. Pharm., **11**, 1—5) who improved the process by substituting chloroform for the mixture of chloroform and ether, and caustic soda for ammonia, and adding 1·5 c.c. of a mixture of equal volumes of water and nitric acid of sp. gr. 1·42 instead of 1 c.c. of nitric acid sp. gr. 1·42.

Gordin (Arch. Pharm., 1902, **240**, 641—4) again altered the proportions. He dissolved 0·2—0·4 grm. of the mixed alkaloids in 15 c.c. of 3 per cent. sulphuric acid, to which was added 3 c.c. of a mixture of equal volumes of water and nitric acid of sp. gr. 1·42, and allowed only 10 minutes to elapse before arresting the reaction. This latter method has been adopted in the 1905 edition of the United States Pharmacopœia.

Thus there is no general agreement about the precise and all-important details of procedure, and we have, therefore, examined the various modifications that have been proposed and certain further ones that the enquiry suggested. Two reactions proceed simultaneously at first—a rapid oxidation of the brucine, and a very much slower oxidation of the strychnine—and the reaction should obviously be stopped as soon as the former is complete.

We have endeavoured to ascertain, therefore: 1. The rate of oxidation of brucine by dilute nitric acid. 2. The rate of oxidation of strychnine by the same. 3. The influence of temperature, varying the time and the concentration of the nitric acid.

We have operated upon the following materials:—Pure brucine (dehydrated), of m. pt. 178° C.; pure strychnine, of m. pt. 269° C., mixtures of the two in known proportions, as well as on the total alkaloid obtained in the assay of *nux vomica* and its galenical preparations. The strychnine has been recovered by distilling off the chloroform from a small tared flask, adding a few c.c. of alcohol when it was almost removed, and, while rotating the flask in an inclined position on the water-bath, passing a gentle stream of air into it. The alkaloid was left as a crystalline deposit over a large area of the flask, which rapidly assumed constant weight, and there was no decrepitation. The residue was finally dissolved in a little dilute acid and tested for brucine with strong nitric acid.

The following table summarises a selection of typical experiments:—

No.	Brucine taken, grm.	Strychnine taken, grm *	Proportion of dilute acid as recommended by	Nitric Acid, grms. per 100 c.c.	Time in mins.	Temp.†	Residue in grm	Remarks.
1	0·15	—	Stoeder	6·5	10	—	0·014	residue included brucine.
2	0·15	—	Stoeder	6·5	60	—	0·001

25	0·15	0·15	—	5·0	10	—	0·165	residue included brucine.
26	0·15	0·15	—	5·0	10	—	0·168	

Experiments 1—7 with pure brucine prove that when the concentration of nitric acid is as high as 7 per cent., the decomposition of the brucine is complete in 10 minutes, and the 90 minutes allowed by Keller is not only unnecessary, but results in the loss of a few per cent. of strychnine (partly compensated for in his original method by impurity introduced by using ammonia). If the concentration, as in experiments 1, 6, 25 and 26, is under 7 per cent., the rate of oxidation falls off rapidly and a longer time elapses before decomposition is complete.

From experiments 8—26 with strychnine and mixtures of strychnine and brucine, the rate of oxidation of the former can be approximately determined. In experiment 17 with 9·0 per cent. of nitric acid 0·008 grm. of strychnine apparently disappeared in three hours, and if we add 0·003 grm., which is the average residue obtained when using 0·15 grm. of brucine, this would mean that 0·011 grm. of strychnine had been oxidised in three hours, or 2·5 per cent. per hour at 18° C. Similarly with Gordin's 8·3 per cent. acid, experiment 18 proves that the oxidation is at the rate of 2 per cent. per hour at 18° C. Howard (Analyst, 1905, **30**, 262) with 9·0 per cent. of nitric acid found in one experiment that 9·9 per cent. disappeared in 3½ hours, or 2·76 per cent. per hour at 21° C., and in another 19·3 per cent. disappeared in 17 hours, or 1·14 per cent. per hour at 21° C.

These results prove that the loss of strychnine by oxidation with dilute nitric acid in 10 minutes is negligible at temperatures up to 25° C., even when the concentration is as high as 15 per cent., but if the time is increased to one hour or more it becomes appreciable, especially in summer time. To overcome this defect in Keller's process, Howard has proposed to carry out the treatment for 1½ hours in ice cold water; but since the reaction is complete in 10 minutes at the ordinary temperature, it is obviously more convenient to carry it out under these conditions.

Influence of temperature.—Experiments 15, 16 and 21 were carried out to ascertain the rate of increase of oxidation of strychnine with rise of temperature, and prove that it is considerable. With Keller's 9 per cent. acid it has risen from 2·5 per cent. per hour at 18° C. to 6·2 per cent. per hour at 30° C.

The assay of nux vomica preparations.—The mixed alkaloids obtained by the process below were separated by oxidation with nitric acid of varying concentration. In the cases that we have examined the strychnine has formed from 33 to 54 per cent. of the total alkaloids. As an example, 10 c.c. of a trial fluid extract gave

* In order to dissolve 0·1—0·3 grm. of strychnine in the 10—15 c.c. of dilute sulphuric acid, as in the above methods, the mixture must be heated, and strychnine sulphate crystallises out on cooling. The nitric acid was always added to the solution with the crystals suspended in it.

† The experiments were all carried out at temperatures between 14° and 20° C., except those specially mentioned.

0·343 grm. of total alkaloid. This, treated by Gordin's process, gave 0·141 grm. of strychnine, after 10 minutes which therefore formed 41·2 per cent. of the total alkaloid. Ten c.c. of the same fluid extract treated for 1½ hours by Keller's process gave 0·138 grm. of strychnine or 40·25 per cent. of the total alkaloid.

Extraction of the alkaloids.—We found the most convenient method of obtaining the mixed alkaloids was to use 10 c.c. of the fluid extract, 50 c.c. of the tincture, or 3 grms. of the extract, in the former cases removing the alcohol by evaporation, and treating the residue with just sufficient cold water to form a syrupy, cloudy fluid. This is transferred to a small separator, and the vessel rinsed out with a few drops of water, 2—3 volumes of chloroform and about 1 grm. of powdered sodium carbonate added and the mixture thoroughly agitated. (If a solution of sodium carbonate is added, or if the extractive is mixed with too much water, resinous matter is thrown out in a form that causes bad emulsions.) The chloroform is separated and the residue extracted twice with more chloroform; the chloroform is mixed and rinsed with a few c.c. of water, most of it is distilled off and shaken into dilute sulphuric acid in three successive stages; the alkaloids are again shaken into chloroform after making the solution alkaline, the chloroform is rinsed and distilled off and the mixed alkaloids weighed. If the amount of strychnine only is required, the alkaloids may be shaken from the first concentrated chloroform solution into a known volume of 3 per cent. sulphuric acid and the nitric acid at once added. For this purpose we prefer to use a total of 33 c.c. and add 3 c.c. of nitric acid of sp. gr. 1·42. The quantity of dilute acid in Keller's and Stoeder's methods (10 c.c.) is too small to effect this operation completely.

We wish to direct attention to the following points, which do not appear to have been sufficiently emphasised, but which are essential if accurate results are to be obtained:—

Part of the product of the action of nitric acid on brucine is of a very feeble acid or phenolic character, and the nature and amount of the alkali which is used to render the solution alkaline, previous to shaking it up with chloroform, has to be chosen accordingly. It is necessary to employ an excess of caustic soda or potash as was done by Stoeder and Gordin. If sodium carbonate is used, much of the decomposition products pass into the chloroform—thus in one experiment 0·3 grm. of brucine, after complete oxidation by nitric acid, yielded 0·170 grm. to chloroform, in presence of a slight excess of sodium carbonate, and in another case 0·2 grm. of brucine yielded 0·091 grm., in a third, with a large excess of sodium carbonate, 0·3 grm. yielded 0·073 grm. to chloroform.

With excess of ammonia the error is smaller, as the following results show—0·15 grm. of brucine, after oxidation yielded in one experiment 0·055 grm., in another 0·045 grm. to chloroform, using a slight excess of ammonia. When a large excess of ammonia was used, 0·2 grm. of brucine gave in one experiment 0·014 grm. and in another 0·015 grm. These residues were always coloured, and almost entirely soluble in dilute soda solution, being free from brucine.

When excess of caustic soda is employed to make the liquor alkaline, the oxidation products are almost entirely retained by the aqueous solution, the mean of six experiments with 0·15 grm. of brucine being 0·003 grm. absorbed by chloroform.

When solutions containing brucine are treated with dilute nitric acid, we have frequently observed that no reaction occurred, and the solution has sometimes remained colourless for an hour. This result we have found depended on the presence or absence of nitrous acid in the sample of nitric acid employed. We found that dilute nitric acid free from nitrous acid had no oxidising action on brucine. This we find has already been shown by Pichard (Comptes rend., 1896, 590), whose results, however, appear to have escaped other writers.

Pichard found that mixtures of brucine and potassium nitrate remained colourless when treated with dilute hydrochloric acid, whereas when potassium nitrite was used instead of the nitrate the usual red colouration was observed, and he proposed the reaction as a test for the detection of small quantities of nitrites. Nevertheless, it is very doubtful we think, if pure nitrous acid acts on brucine, for the oxidation does not proceed unless nitric acid is present also.

Solutions of nitrous acid at temperatures above 0° C., decompose according to the equation, $3HNO_2 = HNO_3 + H_2O + 2NO$. Pichard's reacting materials, therefore, contained nitric acid. We have tried the action of dilute sulphuric acid on brucine, mixed with several times its weight of sodium nitrite, in flasks kept at different temperatures. At 0° C. the solution only slowly assumes a pale orange colour, and the brucine is hardly acted upon, whilst at 20° C. the decomposition is only slow, *i.e.*, 0·15 grm. of brucine and 1·1 grm. of sodium nitrite, dissolved in 30 c.c. of 5 per cent sulphuric acid, after 30 minutes yielded 0·142 grm. of brucine, and a repetition, in which 60 c.c. of dilute sulphuric acid was used, gave the same result. On the other hand, the addition of very minute quantities of nitrites to dilute nitric acid, are sufficient to bring about the oxidation of the brucine; thus 0·5 c.c. of a 1 in 1,000 solution of sodium nitrite, was sufficient to at once start an experiment which was remaining colourless, and the brucine was completely oxidised in 10 minutes.

Experiments were made with more concentrated nitric acid, to ascertain if this would refuse to react with brucine, if it had the nitrous acid removed from it. Preliminary treatment with small quantities of urea enabled us to obtain an acid containing 20 per cent. HNO_3, that had no action on brucine, but with more concentrated acid the reaction took place more or less readily, the decomposition being merely retarded for a few seconds.

Silberrad (this J., 1906, 156) has recently drawn attention to the difficulty experienced in freeing strong solutions of nitric acid from traces of nitrous acid, and we thought that there might be minute traces present, that even urea would not act upon. This appears to be the case, for we find that by treating nitric acid with minute quantities of barium or sodium peroxide, we can obtain a solution containing 50 grms. HNO_3 per 100 c.c., which does not act on brucine after standing some hours. We could not, however, obtain acid of sp. gr. 1·42 that would not react.* The commercial pure acid of sp. gr. 1·42 has always in our experience effected the oxidation of brucine, when added to solutions containing it, the reaction commencing at the instant of contact. Other oxidising agents such as chromic acid, potassium permanganate and ammonium persulphate were not effective.

Urea reacts most effectively when the mixture is heated, the peroxide on the other hand acts best at the ordinary temperature. Volumetric estimation with potassium permanganate, as employed by Silberrad, is not a sufficiently delicate method for detecting such minute quantities as are left after urea treatment, and brucine is a more delicate test. We may say that the acid purified in this way contains traces of some substance—presumably hydrogen peroxide—that reduces permanganate.

The intense orange red colour, observed when nitric acid acts on morphine, has been generally employed as a qualitative test for the latter. It, however, forms a colourless solution in our specially purified 50 per cent. acid. Doubtless nitrous acid plays a part in many other oxidations with nitric acid.† We do not attempt to explain the phenomenon, but it recalls the behaviour of the trace of water vapour, necessary to bring about the combination of some gases, such as hydrogen and oxygen, by the electric spark.

Conclusion.—We find that both Stoeder's and Gordin's conditions lead to slightly more accurate results than Keller's original process. Of the two, Gordin's should have the preference, as it is more expeditious. In any case, the short nitric acid process is capable of accurate results, if the following points are attended to:—

1. For an amount of total alkaloid up to 0·4 grm., the reacting solution should contain at least 7 per cent. of HNO_3.

* Compare Berthelot, Comptes rend., 1898, 127, 143-160.

† *Vide* Ray, J. C. S., 1905, 171.

2. The reaction should be stopped after 10 minutes, when the brucine is entirely oxidised.

3. The temperature should not exceed 25° C.

4. Excess of caustic soda or potash should be used to liberate the strychnine, never sodium carbonate or ammonia.

5. The nitric acid should be added in the form of acid of sp. gr. 1·42, and not more dilute acid, otherwise it may be necessary to add a trace of a nitrite, to start the reaction.

Discussion.

Mr. Whiffen said it was novel to learn that the presence of nitrites or nitrous acid in nitric acid was necessary for the decomposition. He reduced the temperature at which the action took place to as low as —20° C., and found that at that temperature practically no decomposition took place. He did not consider that it was in any way due to the presence or absence of nitrous acid, that at such a low temperature decomposition was not effected. The acid was 50 per cent. (1·420) acid. Passing on to the question of time occupied, the authors mentioned that with 9 per cent. solution an hour and a half was said to be necessary. The process recommended by the New United States Pharmacopœia was about 9 per cent. acid of sp. gr. 1·420, and the time stipulated was 10 minutes at the temperature apparently of the laboratory, not reducing it to any particularly low temperature. He would remind Mr. Reynolds, that in that solution there was nearly 3 per cent. of sulphuric acid present, and that the sulphuric acid had a considerable effect. If the nitric acid they recommended were used without the sulphuric acid being present, the decomposition was much more slow, in fact, the sulphuric acid played an important part in the decomposition. The observation respecting the necessity for the use of caustic alkali such as soda, he fully endorsed. If these experiments were carried out with ammonia, they were not very reliable unless the resulting strychnine was determined by standard sulphuric acid; then there was not much harm done: otherwise if any attempt were made to weigh the resulting alkaloid it was essential that caustic alkali should be used—preferably soda. He was not quite clear whether the 9 per cent. nitric acid referred to was used without the addition of sulphuric acid or in connection with it. If sulphuric acid were present, it might account for the 1½ hours said to be necessary for the decomposition.

Mr. Carr thought that sufficient emphasis had not been laid upon the necessity of ensuring that the nitric acid used contained nitrous acid. As a matter of fact, Mr. Reynolds was led to this enquiry by coming across some nitric acid which was free enough from nitrous acid not to oxidise the brucine when the test was carried out in the ordinary way and at the ordinary temperature.

Mr. Reynolds, in reply to Mr. Whiffen, said in every case the reaction was carried out in the presence of sulphuric acid—either 3 per cent. as recommended by Gordin or 10 per cent. as recommended by Keller. The time recommended by Keller in his original process was 1½ hours, but as they stated it was altogether unnecessary, the reaction being complete at the end of 10 minutes. The conditions, as laid down in the United States Pharmacopœia, were taken from Gordin's paper.

ABSORPTION OF GALLIC ACID BY ORGANIC COLLOIDS.*

BY W. P. DREAPER, F.I.C., AND A. WILSON, B.SC.

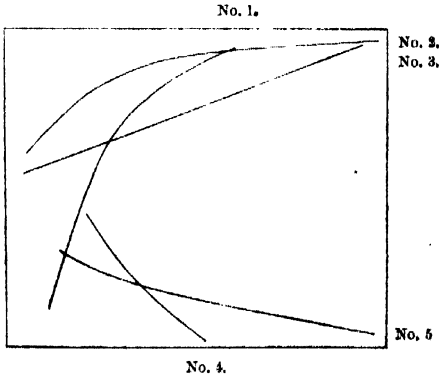
In a previous communication (Proc. Chem. Soc., 22, 70) we have indicated the general reactions which take place when gallic acid is absorbed by certain organic colloids (see also this Journal, 1905, 233). We now give in detail the results obtained. These seem to throw further light on the nature of dyeing and tanning operations generally.

The amount of gallic acid absorbed on the formation of a tannic acid gelatin coagulum was first determined.

A solution of "collin" prepared by the method recommended by Parker and Payne (this J., 1904, 649) was taken as a typical example of an organic colloid which is not coagulated by heat alone. The copper sulphate method of estimating this acid described by one of us (Chem. News, 90—111) was used, precipitation being brought about in the presence of calcium carbonate, the tannic and gallic acids being separated by the lead method.

The addition of gallic acid to a solution of "collin" is without visible effect even after several hours' standing. Tannic acid causes an immediate precipitation, in the presence or absence of gallic acid. The tannic acid used in these experiments was the purest obtainable. It contained a slight amount of gallic acid which was allowed for. Tannic acid (25 grms. per litre) and gallic acid (12·5 grms. per litre); were after mixing in the required proportions, made up to 90 c.c. with water. Thirty c.c. of collin was then added to the mixture in each case. Collin is more sensitive than an ordinary solution of gelatin. It was, therefore, chosen for these experiments, but results of a similar order were obtained with gelatine.

After standing 10 minutes, the precipitated colloid was filtered off, and the gallic acid remaining estimated in 60 c.c. of the filtrate, the copper sulphate solution being of a strength of 15 grms. per litre. In series I., the quantities taken were:—



Thirty c.c. of gallic acid + 30 c.c. "Collin" + tannic acid solution, and water to make up to 120 c.c. The following table shows the amounts of gallic acid carried down by increasing quantities of tannic acid:—

No. of Expt.	Volume of tannic acid solution used.	Gallic acid carried down. as c.c. $CuSO_4$	Gallic acid carried down. percentage of amount present.
	c.c.		per cent.
1	2	3·2	7·7
2	5	4·8	11·6
3	7·5	17·2	42
4	10	21·2	53·3
5	15	30·2	71·9
6	20	33·2	83·0
7	30	39·5	96·2

(See curve No. 1.)

In the second series of experiments, the gallic acid was added after the precipitation of the tannic acid by collin; the object being to determine, if possible, the manner in which gallic acid was removed from solution. The tannic acid solution was made up to 60 c.c. by addition of water, and the collin and gallic acid solutions were then added.

After standing 10 minutes, the mixture was filtered, and the amount of gallic acid remaining in the filtrate was

Addition of reagents (N/1 solution).

* Taken as read.

estimated as before. It was observed that the addition of gallic acid entirely altered the character of the precipitated colloid, for, whilst the "tannin collin" precipitate or coagulum was so finely divided as to give the appearance of milkiness to the liquid, the addition of gallic acid to the milky liquid caused the solid to separate in flocks, leaving the supernatant solution clear.

Expt. No.	Tannic acid solution.	Amount of gallic acid absorbed.	
		as c.c $CuSO_4$	as percentage of amount present.
	c.c.		per cent.
1	2	7·2	17·3
2	5	12·8	30·6
3	7·5	21·0	50·4
4	10	24·8	60
5	15	34·2	80
6	30	40·1	97·3

(See curve No. 2.)

These figures indicate that the gallic acid is absorbed by the precipitated colloid rather than carried down by it at the time of precipitation, or at least, that the one action takes place as readily as the other, and to the same extent.

It was then thought desirable to determine the influence of a third substance, of the nature of an acid, on the absorption power that the tannin-colloid body exerted over gallic acid. With this object in view a series of estimations was carried out in presence of varying quantities of normal acetic acid.

The results observed are indicated in the following table:—

No. of Expt	Acetic acid used.	Amount of gallic acid absorbed.	
		In c.c. $CuSO_4$	percentage on amount present.
	c.c.		per cent.
1	5	13·2	32
2	10	8·8	21
3	20	7·2	17·3
4	30	5·1	12·2
5	50	0·9	2·0

(See curve No. 3.)

In another set of experiments normal hydrochloric acid took the place of acetic acid with the following results:—

Expt. No.	Hydrochloric acid used	Amount of gallic acid absorbed.	
		in c.c. $CuSO_4$	percentage of amount present.
	c.c.		per cent.
1	10	17·2	42·7
2	15	9·6	23·3
3	20	4·8	11·5
4	25	1·2	2·9

(See curve No. 4.)

It will be seen that the presence of a strong acid influences the reaction considerably, 25 c.c. of normal hydrochloric acid being sufficient to altogether prevent the absorption of gallic acid. In order to determine whether any of the acid had been absorbed by the tannin-collin precipitate, the amount of hydrochloric acid present in 30 c.c. of the filtrate was estimated by titrating with normal sodium hydroxide. The result obtained proved that none of the hydrochloric acid had been absorbed.

There is, therefore, no evidence that the stronger acid replaces the weaker one in the coagulum. When estimating the hydrochloric acid in the filtrate, it was noticed that a precipitate formed at the point of neutralisation, which dissolved upon the addition of excess of sodium hydroxide indicating that the original action is a reversible one. The experiment was repeated in the absence of gallic acid, and the same reaction was noticed. It is not clear whether the "tannin-collin" compound is slightly soluble in excess of acid or alkali, and insoluble in a neutral solution; or whether the tannin-collin compound is broken down in presence of excess of either of these reagents. The disturbing influence of a third substance of the nature of a salt was next investigated. The first salt taken was ammonium chloride, the proportions present being as before.

The following results were obtained:—

No. of Expt.	Volume of normal ammonium chloride solution	Amount of gallic acid absorbed.	
		as c.c. $CuSO_4$	percentage on amount present.
	c.c.		per cent.
1	2	22·2	53·3
2	5	22·5	53·8
3	7·5	23·0	55·0
4	10	24·8	60·0
5	20	28·8	77·3
6	30	32·3	87·0
7	50	40·0	97·0

(See curve No. 5.)

These experiments were then extended to other salts.

Normal sodium chloride was substituted for ammonium chloride, with the following result:—

Expt No.	Volume of sodium chloride solution.	Amount of gallic acid absorbed.	
		as c.c. $CuSO_4$	percentage on amount present.
	c.c		per cent.
1	2	25·2	61·1
2	5	26·8	65
3	10	33·8	82
4	20	37·4	90·7
5	30	37·9	91·7
6	50	38·6	93·2

(See curve No. 6.)

These figures show that the influence of a salt on the reaction is exactly opposite to that exerted by an acid, the amount of gallic acid carried down increasing with the addition of the salt in solution.

In order to determine the extent of the absorption power of colloids in the solid state in the absence of tannic acid some experiments were carried out with thin leaf gelatin:—

Experiment I.—30 c.c. of gallic acid and 1·8 grms. of gelatin were added to 90 c.c. of water; the mixture was allowed to stand 2½ hours, and then filtered. The result indicated an absorption of 7 per cent. of the gallic acid, in solution.

Experiment II.—The same quantities were again taken and the mixture allowed to stand 24 hours. In this case there was practically no absorption, but much of the gelatin had gone into solution.

Experiment III.—In this experiment 50 c.c. ammonium chloride (normal) were added to prevent the gelatin from dissolving. The quantities taken were:—1·8 grms. of gelatin, 40 c.c. of water, 50 c.c. of ammonium chloride solution and 30 c.c. of gallic acid solution. After standing two hours the solution was examined, and showed an absorption of 21·4 per cent. of gallic acid originally present in the solutions.

Experiment IV.—In this case alcohol was substituted for ammonium chloride solution, the quantities being: 30 c.c. of gallic acid, 30 c.c. of alcohol, 60 c.c. of water and 1·8 grms. of gelatin. After standing two hours an absorption of 5·8 per cent. was noted.

Experiment V.—1·8 grms. of gelatin, 30 c.c. of gallic acid, 3 c.c. of tannic acid water to make up 120 c.c. Allowed to stand two hours; 10·2 per cent. of gallic acid absorbed.

It will be observed that these results approximate to

those obtained when a soluble colloid (collin) was precipitated by tannic acid.

The presence of a salt distinctly increases the absorption, whilst the addition of alcohol reduces it. The presence of a small quantity of tannic acid also seems to increase the absorption, but the slightly higher value in this case may be due to the tannic acid preventing the solution of a corresponding proportion of the gelatin.

Albumin as a precipitating agent.—With a view to finding whether this absorption property of gelatin was shared with other colloids, experiments were carried out with albumin, using a standard solution of 60 grms. of purest egg albumin per litre throughout the series.

Albumin behaves like collin in that a precipitate is at once produced with tannic acid, whilst a mixture of albumin and gallic acid solutions remains quite clear after several hours' standing.

SERIES I.—A mixture of tannic and gallic acids was treated with albumin, the precipitate filtered off, and the free gallic acid estimated in 60 c.c. of the filtrate. The process was exactly the same as that adopted in the collin series, 30 c.c. of gallic acid being used and made up to 90 c.c. after adding the tannic acid; 30 c.c. of albumin solution was then added. The following results were obtained:—

No. of Expt.	Volume of tannic acid solution used.	Gallic acid carried down. as c.c. $CuSO_4$	Gallic acid carried down. percentage of amount present.
	c.c.		per cent.
1	2	29·2	70
2	5	31·2	75·7
3	10	36·4	88·3
4	20	Free tannic acid present	—

It is clear from the above table that the "tannin-albumin" compound absorbs gallic acid just as freely as the tannin-collin compound, and, therefore, there would be no advantage in using albumin as a precipitant in the valuation of tannins of which gallic acid was a constituent in the place of gelatin or "collin."

SERIES II.—In these experiments the tannic acid was omitted, the precipitation of the albumin being brought about by heat. *Experiment I.*—30 c.c. of gallic acid, 30 c.c. of albumin and 60 c.c. of water were used. The mixture was heated to 93° C., barium sulphate was added to aid separation and the whole filtered. Gallic acid absorbed = 68 per cent.

Experiment II.—The same quantities were again taken, but this time the solution was heated to 100° C. Gallic acid absorbed = 90 per cent.

These results show that the presence of tannic acid is not necessary for the absorption of gallic acid, the condition required being contact with an insoluble colloid.

The influence of salts on the absorption power of albumin is the same as was observed in the case of gelatin. The influence of ammonium chloride is shown in the following example:—A mixture of 30 c.c. of gallic acid, 10 c.c. of tannic acid, and 50 c.c. of N/10 ammonium chloride was treated with 30 c.c. albumin and filtered. Analysis of the filtrate showed that the whole of the gallic acid had been absorbed.

The effect of the precipitation of albumin by alcohol in the presence of gallic acid. The quantities taken were:—30 c.c. of gallic acid and 30 c.c. of albumin with varying amounts of alcohol: the solution was made up to 150 c.c. with water.

Three experiments were carried out in which the amounts of alcohol used were 30 c.c., 60 c.c., and 90 c.c. respectively. In each case practically the whole of the gallic acid remained in solution. The fact that no absorption takes place in the presence of alcohol is of interest.

In the fifth series the precipitation of albumin by alcohol and tannic acid was studied. The quantities taken were as in the last experiment. The tannic acid, alcohol and water were mixed together, and the albumin added last. The results obtained were:—

Expt.	Volume of Alcohol used.	Percentage of tannic acid absorbed.
	c.c.	per cent.
1	90	16
2	70	29
3	50	60
4	0	99

The amount of tannic acid precipitated decreasing with the increased addition of that reagent. The bearing of these figures on the dyeing and tannin actions is noticed later. The action of alcohol is specific; it reduces the absorption of tannic and gallic acids by the precipitated albumin.

The effect of the presence of gallic acid on the precipitation of the "tannin-albumin" compound.

To a solution containing 15 c.c. of albumin, and 40 c.c. of water, 15 c.c. of tannic acid were added.

The solution became cloudy, but no actual precipitate fell; on the further addition of 10 c.c. of gallic acid an almost complete separation of the albumin compound took place. This point would seem to be of interest in connection with the tanning of leather, indicating the probable action of gallic acid in the presence of tannic acid. It is even possible that with tannic acid of absolute purity, no precipitation would take place with such substances as albumin. An acid of such purity has never been prepared. It was, therefore, impossible to investigate this point.

It is interesting to note also that when the proportion of water present is reduced, the following results were obtained:—

1. 15 c.c. of albumen, 40 c.c. of water and 15 c.c. of tannic acid (see above).

2. 15 c.c. of albumin, 20 c.c. of water and 15 c.c. of tannic acid.

There was more precipitate than in 1, but the addition of 10 c.c. of gallic acid greatly increased it.

3. 15 c.c. of albumin, 10 c.c. of water and 15 c.c. of tannic acid.

There was more coagulation than in 2, but the addition of the gallic acid solution still increased it.

4. 15 c.c. of albumin and 15 c.c. of tannic acid.

A bulky precipitate was obtained which was not visibly increased by the addition of gallic acid.

Further consideration will be given to this matter.

The nature of the tannin albumin coagulum.—The following figures show the proportion of tannic acid absorbed by a precipitated tannic acid albumin coagulum. The amount of albumin taken was 1·2 grms. and the total volume of the solution being 120 c.c. in each case.

Expt. No.	Tannic acid used.	Tannic acid absorbed.
	grms.	grms.
1	0·375	0·375
2	0·5	0·45
3	0·75	0·49
4	1·25	0·60
5	1·75	1·0
6	2·5	1·27
7	3·5	1·45

The amount of tannic acid in Experiment I. was just sufficient to precipitate the albumen present. These figures indicate that the tannic acid is absorbed by the coagulum. There is no evidence of chemical action so far as these figures go.

In view of the above results it was considered important to test the action of different reagents (salts, acids, alcohol, &c.) on the power of absorption exerted by silk over tannic and gallic acids. At present it is only proposed to submit the figures obtained when alcohol was the reagent used.

Thirty c.c. of tannic acid were used with varying amounts of alcohol made up with water = 120 c.c. In each case 1·8 grms. of boiled-off silk were left in contact with the solution for 2½ hours, and the liquid was then examined for tannic acid.

Expt.	Alcohol used.	Tannic acid absorbed.
	c.c.	per cent.
1	0	15
2	70	4·6
3	90	1·2

It is interesting to note that with this colloid (fibroin) practically the same result was obtained as with gelatin and albumin respectively. The presence of alcohol diminishes the amount of tannic acid absorbed by the fibre.

This reaction seems parallel to the extraction of the colour from silk dyed with Night Blue by treatment with alcohol. Knecht claims that he has isolated the Night Blue amino acid compound from dyed silk, and states that the existence of this compound indicates that a chemical combination has taken place between silk and dye, and that this compound is soluble in alcohol or benzene. So far as our experiments go we find no indication that such an action takes place in the cases under review, but rather that the altered solubility of the two acids accounts for the reduced absorption by the organic colloids in presence of alcohol.

We hope to study this subject in greater detail.

Absorption of tannic and gallic acid by hide powder or leather.—Working on the lines adopted in the foregoing experiments, we found that the presence of alcohol prevents the absorption of tannic and gallic acids by hide powder.

Two examples illustrate this:—

Experiment I.—1·8 grms. of hide powder, 90 c.c. of water, and 30 c.c. of tannic acid were allowed to stand two hours, filtered and examined; 72 per cent. of the added tannic acid was absorbed.

Experiment II.—1·8 grms. of hide powder, 90 c.c. of alcohol, 30 c.c. of tannic acid were used. After standing two hours this also was filtered and examined, when it was found that only 10 per cent. of tannic acid had been absorbed.

So far as this goes, it indicates that the process of tanning is of the same nature as that of dyeing, and that both processes are similar in their effect to the absorption of these acids by gelatin or albumin.

The conclusions drawn from these experiments are as follows:—

1. That the tannin-gelatin coagulum readily absorbs gallic acid is confirmed.

2. The removal of the gallic acid is independent of the actual precipitating process of the tannin coagulum.

3. The degree of absorption of gallic acid is greatly influenced by the presence of other substances:

(*a*) Solutions of salts tend to increase the absorption factor.

(*b*) Acid solutions reduce the proportion of gallic acid absorbed.

(*c*) Alcohol in sufficient quantity altogether prevents the absorption of both tannic and gallic acids.

(4) Absorption takes place with solid gelatin, but at a reduced rate.

The effect of adding salt solutions, and alcohol, is the same as when a dissolved gelatin (collin) is used.

5. Albumin behaves like gelatin when used as a precipitant for tannins.

6. Albumin precipitated by heat absorbs gallic acid as readily as when the precipitation is brought about by tannic acid from aqueous solutions.

The presence of alcohol greatly modifies the reaction.

7. Acids and salts influence the rate of absorption as in the case of gelatin. The presence of gallic acid influences the precipitation of the tannic acid albumin coagulum.

8. Pure silk fibre (fibroin) seems to possess the properties of these other colloids in its behaviour towards tannic and gallic acids.

9. Hide powder behaves like other colloids in the above respects.

These results seem to throw light on the solution state of these substances. It is shown that coagulation may take place by stages. A tannic-acid-albumin complex, which is still in the pseudo-solution or hydrosol state, may be coagulated by the addition of gallic acid. The coagulum consists of the three reagents involved in the reaction. It is assumed that in this special case the addition of tannic acid increases the degree of aggregation of the solute, and, by degrading its solution state, brings it within the range of the action of the gallic acid, causing actual desolution with separation of a coagulum. When this substance which causes desolution is in a state of pseudo solution it may be carried down in large quantities.

One of us (Dreaper, this J., 1905, 233) recently advanced the hypothesis that the desolution effects obtained in dyeing seem to indicate that "within certain limits of concentration, and when once an equilibrium has been established, and when the action is a reversible one, the aggregates in any pseudo solution system are of equal size, this state being brought about by molecular migration." These results seem to confirm this view, which has already received the general support of Linden and Picton (Trans. Chem. Soc., 1905, 1933). With very concentrated solutions of gallic acid and albumin, where it is assumed the state of aggregation is correspondingly great, coagulation may even take place in the absence of tannic acid. The exact conditions of this reaction are being observed.

The influence of the ratio of solution/solute in these experiments indicates the close relationship existing between them even in these abnormal cases of pseudo-solution.

The influence of the presence of alcohol on the formation of a tannic acid coagulum indicates that the action is of the same order in the case of both tannic and gallic acids. Coagulation is induced under suitable conditions of solution by both acids depending on the state of aggregation of the colloid. As this increases, the action of these acids is correspondingly increased, until a point is reached when even gallic acid is able to coagulate the colloid either in the presence or absence of tannic acid. In the latter case, under conditions which would otherwise be outside the coagulating limit. The normal state of equilibrium may also be disturbed by the presence of a soluble salt or by the presence of another reacting colloid. In the presence of alcohol in which the tannic and gallic acids are more soluble if the reactions involved are due to absorption, the results obtained would be of the order indicated. In the presence of acids (hydrochloric acid) the reduced action is partly due to the gelatin and tannic acid, both being present in the soluble state as well as in the coagulum.

In any case an equilibrium is established which may or may not lead to actual coagulation. The results depend on the relative proportions of the substances present and the ratio of solution to solute.

Further work will be undertaken to determine the reactions, if any, with inorganic colloids and also the further study of this subject generally.

PROF. HENRY LOUIS IN THE CHAIR.

SCHEIBLER'S APPARATUS FOR THE DETERMINATION OF CARBONIC ACID IN CARBONATES; AN IMPROVED CONSTRUCTION AND USE FOR ACCURATE ANALYSIS.

BY S. H. COLLINS.

The estimation of the carbonic acid in those carbonates which are readily decomposed by hydrochloric acid is one of the commonest determinations that fall to the lot of the analyst. The relative simplicity and rapidity of gasometric methods causes the analyst to prefer such

methods over others, Scheibler's method being one of the best known modes of obtaining and measuring the gas.

As has been pointed out by other writers, some forms of Scheibler's apparatus are inaccurate. For example, Mr. A. D. Hall, in the *Journal of the Chemical Society*, 1902, Trans. 81, writes, "With small proportions of calcium carbonate, 0·5 per cent. and below, Scheibler's apparatus becomes unworkable, for all the gas produced remains in the reacting acid," and A. Amos, in the "Journal of Agricultural Science," 1905, 322, writes "The volumetric method of Scheibler also cannot be used for soil containing only 0·5 per cent. of lime because all the carbon dioxide remains in solution in the decomposing acid." But I find that 0·01 per cent. of carbon dioxide is well within the limits of the apparatus I use, and indeed 0·001 per cent. could be measured, if there were any use in doing so.

The errors in Scheibler's method are due to several causes:—

(1) *Temperature.*—In gas analysis having any pretensions to accuracy, the effect of temperature is most important. In Scheibler's method, the gas given off on adding acid to a carbonate is only a fraction of the total gas dealt with, there always being a comparatively large amount of air present; the effect of temperature is in consequence multiplied. For example, if the carbon dioxide evolved be 15 c.c. and the air in the apparatus be 150 c.c., then the error due to temperature is 10 times as much in Scheibler as in other gas analysis. The measurement of temperature must, therefore, be very exact, for which purpose a water-cooling arrangement is absolutely essential.

As a compromise of all the considerations in this paper, I think that for ordinary work a decomposing flask of 150 c.c. will prove to be the best size. If in such a flask the volume occupied by substance, acid, &c., be 14 c.c., then there will be 136 c.c. of air in the flask, on which a variation of 0·4° C. will cause a variation of 0·2 c.c., equal to an error of .1 per cent. on 20 c.c. of carbon dioxide. Owing to the heat of combination of reacting substances, change of temperature of room, presence of operator, &c., I find in practice that 2 litres of water are necessary to obtain a sufficient uniformity of temperature. The less surface exposed by the water-cooler to the air of the room the better; also much can be gained by making all parts of the apparatus contribute to this constancy of temperature. At once the simplest and most efficient means of obtaining these ends is to bodily sink the apparatus under water, and the improvement I propose in construction is principally obtained by that means.

The suggestion has been made by many other workers that the size of the decomposing vessel might be diminished but this solution of the difficulty only increases other errors, which I now propose to deal with.

(2) *Solubility of the carbon dioxide in the water and acid used to decompose the carbonate.*—The amount of carbon dioxide dissolved in the acid liquors can be calculated from the known laws of gases. At 15° C. water dissolves its own volume of gas measured at the partial pressure which it is exerting on the acid or water, the volume of gas dissolved being:—

$$\text{volume of water} \times \frac{\text{volume of carbon dioxide}}{\text{volume of total gas}}$$

Let—

f = the capacity of the decomposing flask in c.c.

a = the volume of acid used in c.c.

g = the volume of gas measured in the burette in c.c.

s = the number of c.c. of gas dissolved by 1 c.c. of water.

v = the true volume of gas in c.c.

Then the amount of gas dissolved is $\frac{asg}{f+g-a}$* and

$$v = g\left(1 + \frac{as}{f+g-a}\right)$$

Further let—

B = the height of the barometer in millimetors.

t = the temperature in degrees centigrade.

T = aqueous tension in millimeters.

w = the weight of substance taken in grms.

Then—

$$\frac{g\left(1 + \frac{as}{f+g-a}\right) \times (B-T) \times 0{\cdot}1964}{760(1+\delta t) \times w} = \text{the per cent. of } CO_2 \text{ in the substance.}$$

The expressions $760(1+\delta t)$, T and s being all functions of t are given together in Table I.

TABLE I.

For calculating $\frac{g\left(1 + \frac{as}{f+g-a}\right) \times (B-T) \times 0{\cdot}1964}{760(1+\delta t) \times w}$

t	760 (1+δt)	T	s
12	793	10	1·11
13	796	11	1·07
14	799	12	1·04
15	802	13	1·00
16	805	14	0·98
17	807	14	0·96
18	810	15	0·93
19	813	16	0·91
20	816	17	0·89
21	818	18	0·87
22	821	20	0·84
23	824	21	0·81
24	827	22	0·78
25	830	24	0·75
26	832	25	0·72
27	835	27	0·70
28	838	28	0·68
29	841	30	0·66
30	844	32	0·64
31	847	33	0·62
32	849	35	0·60
33	852	37	0·58
34	855	40	0·56
35	857	42	0·54
36	860	44	0·52
37	863	47	0·50
38	866	50	0·49
39	868	52	0·48
40	871	55	0·47

Some objections might be taken to this formula.

The solubility of carbon-dioxide in hydrochloric acid might be less than that in water. The acid used, however, cannot conveniently be stronger than one part of strong acid to three of water, and cannot be much weaker than 1 to 10; the experiments have somewhat exceeded this range and give no indication of any error due to this cause, and, as will be shown later, the much more serious effect of calcium chloride, though easy to show under experimental conditions, is too small to be of any practical consequence in actual work.

It might be argued that the formula would be only true if all the gas were given off before any passed into the burette, and that the true formulæ would be

$$v = g\left(1 + \frac{as}{f-a}\right)$$

Experiments show that this modified formula is wrong, for example:—

Expt.	B	t	f	a	g	Grms of carbon dioxide found: correct formula.	Grms of carbon dioxide found: incorrect formula.	Grms of carbon dioxide taken.
L	761	16·0	85	25	25·45	0·0596	0·0654	0·0594
M	757	29·0	145	40	26·52	0·0540	0·0563	0·0543
N	740	14·4	145	35	23·90	0·0541	0·0564	0·0543

All the other experiments confirm the formula,

$$v = g\left(1 + \frac{as}{f+g-a}\right)$$

* In a few special cases the volume occupied by the solid to be tested must be subtracted from the denominator, but, as a rule, this correction is needless.

Under certain limited conditions, the above formula can be simplified. For example: if, a, is less than one-tenth of, f; g, less than one-fifth of, f, and, t, between 13 and 19°C., then the error of the formula

$$v = g(1 + \frac{a}{f})$$

is less than 1 per cent.

Within the above limitations, if, $f = 215$ c.c., and $a = 15$ c.c., then $\frac{a}{f}$ is 7 per cent., which is the correction advocated by Prof. Warrington.* With a flask of that size, in the absence of any water-cooler, an error of 10 per cent. due to change of temperature must be of frequent occurrence.

The second improvement I suggest is in the method of working out the result. As the calculations involved in the above formula are lengthy, I include Table II., and have prepared a slide rule of fair range, which I trust will render the working simple. The fraction $\frac{as}{f+g-a}$ is rarely more than one-tenth, hence an error of 10 per cent. in measuring that fraction will only make an error of 1 per cent. in the final result.

(3) The above equation can only be correct if the acid CO_2 and air in the flask have reached equilibrium, which can only be achieved by violent shaking. Scheibler recognised this fact by providing a fair length of rubber tube and a gutta tube for holding the acid. Much of the trouble recorded with this instrument is due to neglect of the necessity for violent shaking.

The improvement I suggest under this head is to substitute a tube of transparent celluloid for the gutta tube, or, if glass be essential, the device shown in Fig. 1.

(4) *The disturbing influence of various salts.*—Substances such as calcium chloride may be present in varying amounts, and such substances will reduce the solubility of the carbonic acid in the water used. A simple means of correcting for this decrease in solubility is to deduct a certain amount from the amount of acid actually used, and to calculate the result as if less acid had been used than was actually the case. The amount to be deducted will depend upon the salt, as given in Table III., which is calculated from data given in Comey's "Dictionary of Solubilities."

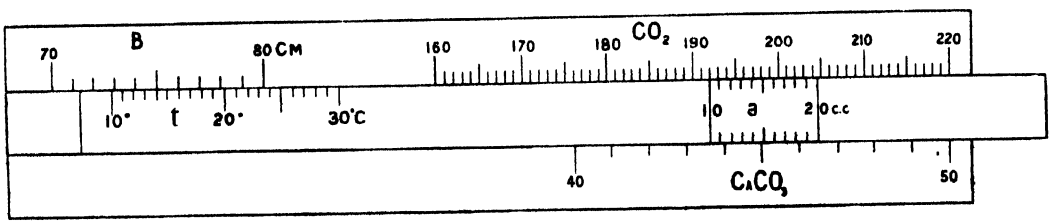

TABLE II.

Mgrms. of CO_2 corresponding to 1 c.c. of gas measured. Flask (f) 150 c.c.

	Bar = 760 mm. Gas measured (g) = 20 c.c. Acid (a) in c.c.							B (mm.) 750 770 — +	B (mm.) 740 780 — +
° C.	10	15	20	25	30	35	40		
12	1·98	2·06	2·14	2·22	2·30	2·39	2·49	0·03	0·06
14	1·96	2·03	2·10	2·18	2·26	2·34	2·44	0·03	0·05
16	1·93	2·00	2·06	2·13	2·21	2·29	2·38	0·03	0·05
18	1·91	1·97	2·03	2·09	2·16	2·24	2·33	0·03	0·05
20	1·88	1·94	2·00	2·06	2·12	2·20	2·28	0·03	0·05
22	1·86	1·91	1·96	2·02	2·08	2·15	2·23	0·03	0·05
24	1·83	1·89	1·93	1·99	2·04	2·10	2·18	0·03	0·05
26	1·81	1·86	1·90	1·95	2·00	2·06	2·13	0·03	0·05
28	1·78	1·83	1·87	1·92	1·96	2·01	2·08	0·03	0·05
30	1·76	1·81	1·84	1·89	1·92	1·97	2·03	0·03	0·05
32	1·73	1·78	1·81	1·85	1·89	1·93	1·98	0·02	0·05
34	1·71	1·75	1·78	1·82	1·85	1·89	1·94	0·02	0·05
36	1·68	1·72	1·75	1·79	1·82	1·85	1·90	0·02	0·05
38	1·66	1·69	1·72	1·76	1·79	1·82	1·86	0·02	0·05
g 0 +) 40 —)	0·01	0·02	0·03	0·04	0·05	0·06	0·08	corrections	
10 +) 30 —)	0·00	0·01	0·01	0·02	0·02	0·03	0·04		

Examples (α) $a = 20$, $t = 22$, Bar. = 750, $g = 10$
∴ 1 c.c. gas = 1·96 — 0·03 + 0·01 = 1·94 mgrms CO_2

(β) $a = 30$, $t = 32$, Bar. = 770, $a = 40$
∴ 1 c.c. gas = 1·89 + 0·02 — 0·05 = 1·86 mgrms CO_2.

Slide Rule Example.

Example (α) $t = 14°$ C., B = 750 mm., $a = 10$ c.c., then 1 c.c. gas measured = 1·92 mgrms. $CO_2 = 4·36$ mgrms. $CaCO_3$.

Example (β) $t = 20°$ C., B = 782 mm., $a = 20$ c.c., 1 c.c. of gas measured = 2·05 mgrms., $CO_2 = 4·64$ mgrms. $CaCO_3$.

* See Chem. News, 31, 253.

In order to test whether these figures worked true in practice, the following experiments were performed :—

Expt.	B	t	f	a	g	Carbon dioxide, grms. found uncorrected.	found corrected.	taken.	grms. $CaCl_2$.
O.	757	18·9	145	55	24·62	0·0629	0·0559	0·0543	10
P.	738	14·4	145	45	24·02	0·0583	0·0548	0·0543	5

The correction is therefore approximate.

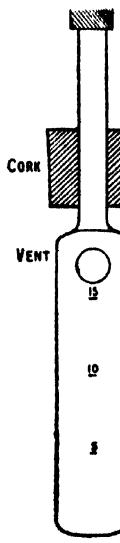
The above conditions are very severe; I do not know of any actual case that could arise in practice similar to it.

The following are actual cases that have occurred :—

Crude phosphate, uncorrected, 26·96 per cent.; corrected, 26·92 per cent. carbon dioxide.

Gypsum, uncorrected, 1·78 per cent.; corrected, 1·77 per cent. carbon dioxide.

Burnt lime, uncorrected, 1·03 per cent.; corrected, 1·02 per cent. carbon dioxide.



In actual practice the correction is not worth the trouble of making, it is too insignificant.

The effect of unknown amounts of calcium chloride and other salts has therefore been exaggerated by former writers, but in those rare cases, if there are any at all, where a correction is needed, Table III. may be used.

TABLE III.

For 1 grm. of	deduct c.c. acid.
Ammonium chloride	1
Potassium chloride	1
Gum	1
Sugar	1
Calcium chloride	2
Sodium chloride	2
Potassium nitrate	2
Sodium nitrate	2
Potassium sulphate	3
Sodium sulphate	3

(5) A subject, commonly referred to in connection with Scheibler's instrument, is the error due to absorption of carbon dioxide by the water in the burette. In Scheibler's original apparatus a flexible gas bag wa supplied in a separate bottle. Such an arrangement onl introduced much larger errors than it removed; th alteration in volume due to change of temperature i large, whilst the loss of gas by absorption is small. Wher the decomposing vessel is small the risk of absorption ma be important, but, for reasons given below, the instrumen shown in Fig. 2 permits no measurable loss.

GLASS TUBE FOR ACID

FIG. 1.

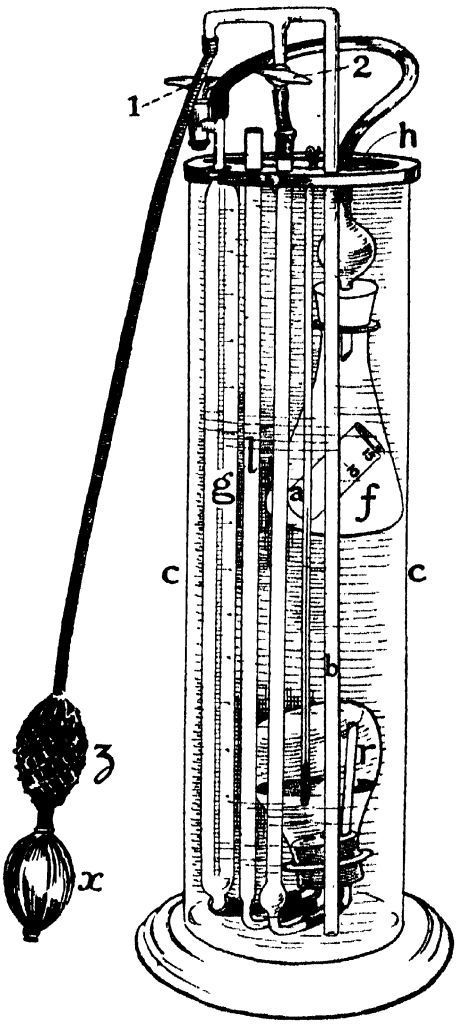


FIG 2.

Above the decomposing flask is placed a small bulb to prevent acid splashing up into the rubber tubes. This bulb, together with the rubber connecting tube, holds about 15 c.c. If 15 c.c. of gas pass into the burette, no carbon dioxide passes into the burette at all; the error by absorption is *nil*. If 30 c.c. of gas pass into the burette,

only 15 c.c. of this has come from the flask and that 15 c.c. is not pure carbon dioxide, but gas derived from a mixture of 30 c.c. of carbon dioxide and 140 c.c. of air. There is only $15 \times \frac{30}{170}$ c.c. carbon dioxide in the burette diluted to 30 c.c. with air, that is, 8·8 per cent. Gas of such concentration would need 3·4 c.c. of water to be saturated before 0·3 c.c. had been absorbed; hence an error of 1 per cent. is utterly impossible.

(6) *Alteration of volume by bending the rubber connections.*—The rubber connections should be of thick-walled, narrow bore rubber tube; thin tube is apt to "kink" and decrease the volume one to two-tenths of a c.c. So long as the rubber stopper does not exceed 3 cm. diameter no change of volume will occur from the bulging of the rubber stopper.

(7) *Occluded gas.*—Many finely-divided substances have the power of occluding gases on the surface; such occluded gas might interfere with the estimation of combined carbon dioxide. In the case of soils the amount of gas given off by decreasing the pressure or increasing the temperature is often greater than the amount of gas given off by adding acid. In the modification of Scheibler that I recommend the temperature is kept very constant, and the pressure only varies temporarily and to a small extent. Errors under this head are therefore unlikely, but I have tried several experiments to settle the question. I have placed several soils in the decomposing flask, and used water instead of acid in the celluloid tube. In no case have I observed any alteration of volume greater than 0·1 c.c.

In the experiments below I have used sand (25 grms.) and a heavy loam soil (10 grms.) with much humus, both previously extracted with hydrochloric acid, washed and air dried; to which have been added, in the case of the sand, a measured amount of a standard solution of sodium carbonate, and in the case of the soil, a weighed amount of calcium carbonate.

Expt.		B.	*t*	*f*	*a*	*g*	grms. of carbon dioxide. found	grms. of carbon dioxide. taken	per cent of carbon dioxide. found	per cent of carbon dioxide. taken
K	Sand	765	16·2	140	20	1·15	0·0024	0·0027	0·010	0·011
Q	Soil	750	15·4	150	20	1·00	0·0021	0·0025	0·021	0·025

As anticipated, no errors occur from occluded gas.

*Description of the instrument.**—The carbonate is weighed and placed in flask, *f*, the acid in tube, *a*, taps 1 and 2 opened, the flask connected up with the rubber stopper, plunged under the water in cooler, *c*, and kept there by means of the hook, *h*, engaging with a projection on the collar. Tap 2 is closed and air blown through the tube, *b*, so as to stir up the water in the glass cylinder, *c*, and obtain uniform temperature. Tap 2 is opened and the rubber bulb, *z*, gently squeezed till the water in the burette, *g*, stands at zero, tap 1 being closed with the other hand. On letting go the bulb, *z*, the level in tube 1 sinks to the bottom, when the flask, *f*, is removed from the water, the acid spilled, the flask shaken violently, returned to the water, the level adjusted by squeezing the bulb, *z*, shutting tap 2, and the volumes of gas, *g*, measured. The process of stirring, shaking and adjusting level should be continued till a constant reading has been obtained. The temperature of the water is taken by a thermometer, graduated 0° to 40° C. in fifths of a degree; the gas burette is graduated 0 to 50 c.c. in tenths of a c.c. If the temperature should vary one or two fifths of a degree during the process of the experiment, correction can easily be made, since a rise of one mark on the thermometer means that one mark on the burette must be subtracted; for 136 c.c. of air expand 0·1 c.c. for a rise of 0·2° C. With 14 c.c. of acid the amount of air left in a 150 c.c. flask would be 136 c.c.; the amount of acid used would never vary from this figure sufficiently to make any appreciable error in the correction used.

It is important to see that reservoir, *r*, is half full of water, and that the bulb, *z*, is half full of air before levelling.

* The instrument, slide rule, tables, &c., can be obtained from Messrs. Brady and Martin, Newcastle-upon-Tyne.

The tubes are held in place by an ebonite collar at the top of the cylinder and a piece of brass wire gauze ¼-inch mesh placed inside the jar (not shown).

A test occupies 10 minutes time.

Table IV. contains some additional experiments, which serve to show that the principle here worked out applies over a long range.

Table V. is useful in showing at a glance the degree of accuracy necessary in the various measurements needed. It will be seen that, so long as the decomposing flasks are picked, no exact measurement is necessary.

Where a direct reading instrument is required Table VI. may be used. By weighing 0·2 grm. of limestone, 2 grms. of burnt lime or 20 grms. of soil, and using the amount of acid indicated in Table VI., each c.c. of gas measured represents 1 per cent., 0·1 per cent., or 0·01 per cent. of carbon dioxide respectively.

This table is less accurate than Table II., but an error of 2 per cent. will be practically impossible. The difference between 10·0 per cent. and 10·2 per cent. and so on is often of little consequence, and is usually less than errors of sampling. By weighing 0·45 grm. or 4·5 grms. direct reading in per cent. of calcium carbonate can be obtained by Table VI.

My thanks are due to Mr. R. G. Hatton and Mr. H. R. Cullen for the drawings.

18° C	25	23	21	19	17	15	13
20° C	27	25	23	21	19	17	15
22° C	29	27	25	23	21	19	17

In order to test whether these figures worked true in practice, the following experiments were performed :—

Expt.	B	t	f	a	g	Carbon dioxide, grms. found uncorrected.	found corrected.	taken.	grms. $CaCl_2$.
O.	757	18·9	145	55	24·62	0·0629	0·0559	0·0543	10
P.	738	14·4	145	45	24·02	0·0583	0·0548	0·0543	5

The correction is therefore approximate.

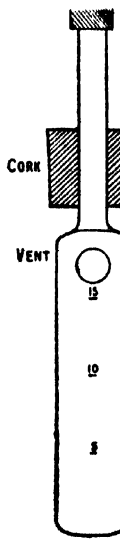
The above conditions are very severe; I do not know of any actual case that could arise in practice similar to it.

The following are actual cases that have occurred :—

Crude phosphate, uncorrected, 26·96 per cent.; corrected, 26·92 per cent. carbon dioxide.

Gypsum, uncorrected, 1·78 per cent.; corrected, 1·77 per cent. carbon dioxide.

Burnt lime, uncorrected, 1·03 per cent.; corrected, 1·02 per cent. carbon dioxide.



In actual practice the correction is not worth the trouble of making, it is too insignificant.

The effect of unknown amounts of calcium chloride and other salts has therefore been exaggerated by former writers, but in those rare cases, if there are any at all, where a correction is needed, Table III. may be used.

TABLE III.

For 1 grm. of	deduct c.c. acid.
Ammonium chloride	1
Potassium chloride	1
Gum	1
Sugar	1
Calcium chloride	2
Sodium chloride	2
Potassium nitrate	2
Sodium nitrate	2
Potassium sulphate	3
Sodium sulphate	3

(5) A subject, commonly referred to in connection with Scheibler's instrument, is the error due to absorption of carbon dioxide by the water in the burette. In Scheibler's original apparatus a flexible gas bag wa supplied in a separate bottle. Such an arrangement onl introduced much larger errors than it removed; th alteration in volume due to change of temperature i large, whilst the loss of gas by absorption is small. Wher the decomposing vessel is small the risk of absorption ma be important, but, for reasons given below, the instrumen shown in Fig. 2 permits no measurable loss.

GLASS TUBE FOR ACID

FIG. 1.

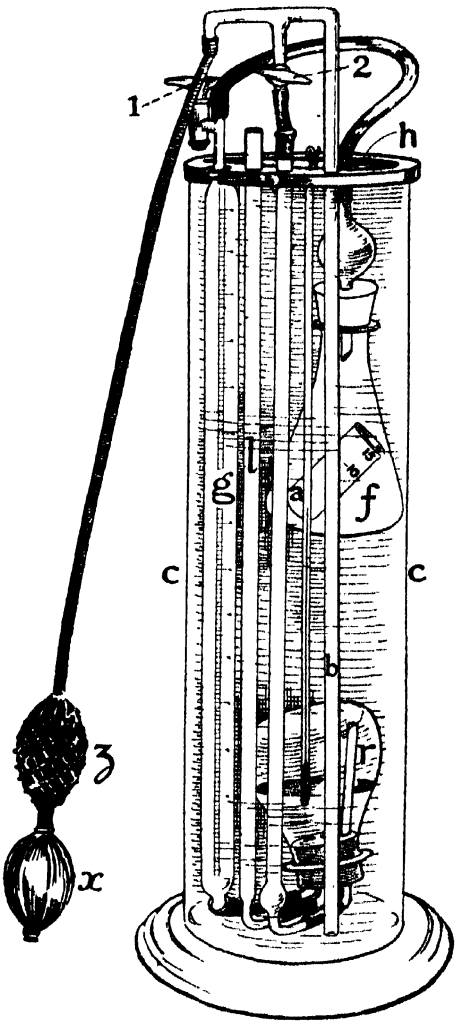


FIG 2.

Above the decomposing flask is placed a small bulb to prevent acid splashing up into the rubber tubes. This bulb, together with the rubber connecting tube, holds about 15 c.c. If 15 c.c. of gas pass into the burette, no carbon dioxide passes into the burette at all; the error by absorption is *nil*. If 30 c.c. of gas pass into the burette,

which the air is conducted away for use by the pipe, *m*. The tubes, *a* and *b*, are filled with water or other liquid, and *b*, communicates by a branch with the reservoir, *d*, and has two valves, *e*, *f*, which prevent the water and air from passing down the pipe, *b*. The water is made to flow down the tube, *a*, in the direction of the arrow by the propeller, *h*, and draws along with it the air which is injected through the pipe, *j*, by the blower, *i*. The mixture of water and air separates after entering the reservoir, *g*; the water passes up the pipe, *b*, to be used over again, any excess passing to the tank, *d*, and the air collects in, *g*, and is compressed by the weight of the liquid columns in *a* and *b*. Should too much air collect in the reservoir, *g*, the excess can escape through the small pipe, *l*, into the pipe, *b*. In modified forms of the apparatus, rotary blowers or turbines are used to move the liquid and to inject the air, and they may be placed near the bottom of the "upward" pipe. —W. H. C.

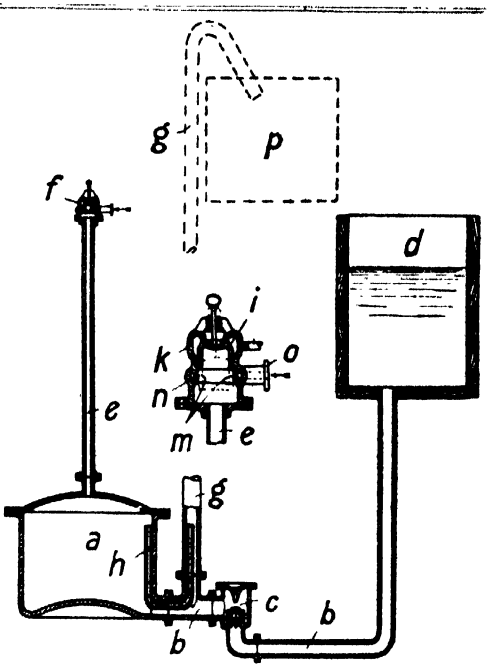
Vacuum pans and like evaporators. A. J. Boult, London. From Milwaukee Evaporator Co., Milwaukee, U.S.A. Eng. Pat. 14,379, July 12, 1905.

SEE U.S. Pat. 794,831 of 1905; this J., 1905, 880.—T. F. B.

Evaporating, distilling, concentrating and like purposes; Method of and apparatus for treating liquids and semi-liquids for —— with continuous re-utilisation of the heat employed. E. Theisen, Munich, Germany. Eng. Pat. 19,385, Sept. 25, 1905.

SEE Fr. Pat. 356,752 of 1905; this J., 1906, 8.—T. F. B.

Filters; Impts. in ——. A. J. Boult, London. From E. Goldman and Co., Chicago. Eng. Pat. 18,833, Sept. 18, 1905.

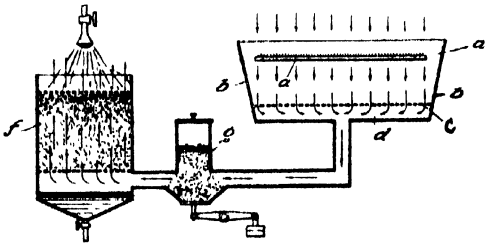


THE claim is for improvements in the filters described in Eng. Pat. 8984 of 1905 (this J., 1905, 1054), and consists in replacing the cloths on the distributor- and collector-plates by perforated metal screens.—W. H. C.

Furnaces; Impts. in the construction of regenerative ——. J. H. Brown, Nottingham. Eng. Pat. 20,318, Oct. 7, 1905.

THE control of the distribution of the waste gases to the regenerative flues, formed in the division walls of the furnace, is effected by damper tiles placed over the inlet ports to the flues and adjusted by an iron bar, introduced through doors in the furnace front. By similar means the gases coming from the regenerative flues are separated into two currents; one of which passes directly to the main flue, while the other passes first beneath the ash-pan and causes the evaporation of the water contained therein. The secondary air is distributed evenly over the air-heating flue by baffle-walls.—W. H. C.

Raising liquids by direct fluid pressure; Apparatus for ——. F. Girod, Berlin. Eng. Pat. 26,668, Dec. 21, 1905.



THE liquid enters the pressure chamber, *a*, from the store tank, *d*, through the tube, *b*, which is provided with a valve, *c*, driving out the air through the tube, *h*, into the delivery pipe, *g*. As soon as the level of the liquid covers the end of the tube, *h*, the escape of the air is stopped, and then the pressure exerted by the column of liquid in *g*, compresses the remainder of the air in *a*, and when a sufficient degree of compression is reached, the air inlet valve, *f*, at the top of the tube, *e*, is opened. This valve consists of a cup-shaped valve, *i*, contained in a casing, *k*, and is shown open in the figure; when closed, it occupies the position indicated by the dotted lines. The air from the compressor enters the valve by the pipe, *o*, passes into the annular passage, *n*, and, when the valve is open, through the narrow orifices, *m*, and the pipe, *e*, into the chamber, *a*, and causes the inlet valve, *c*, to close. The liquid is forced up the delivery pipe, *g*, into the overhead tank, *p*, and when *a*, is empty of liquid, the compressed air escapes also through *g*, the valve, *f*, closes, *c*, opens, and the whole process is repeated. A modification of the air inlet valve is claimed, in which the opening is effected by means of combination of a lever and diaphragm.—W. H. C.

UNITED STATES PATENTS.

Vapours of volatile solvents; Apparatus for recovering the ——. E. Bouchaud-Praceiq, Paris. U.S. Pat. 806,866, Dec. 12, 1905.

THE apparatus described is intended for recovering the vapours or volatile solvents, used for example in the manufacture of smokeless powder, artificial silk, &c. It consists of a frame, *a*, provided with openings, from

which the material to be treated passes, mounted in a vaporising chamber, *b*, which is open to the atmosphere. The chamber has a false bottom, *c*, through which the air, charged with vapours, descends into a drain, *d*, and passes to the air-purifying chamber, *f*, passing, on its way, through drying material contained in a vessel, *g*, provided with a cleaning-plug for the removal of saturated material. The chamber, *f*, contains pumice-stone saturated with fixing agents, by which the volatile vapours are removed from the air, so that on leaving the top of this chamber the air may be returned to the vaporising chamber to take up a fresh amount of vapour. The arrows show the circulation in the apparatus. The chambers are so arranged relatively to each other that the pressure of the column of fluid in the connecting passage is greater at the vaporising chamber end than at the other end, "whereby the fluid will be automatically and naturally propelled through the system by the force of gravity."

The claims also include an arrangement to prevent the loss of air, charged with vapours, over the edge of the vaporising chamber. This consists of an apron, or curtain, of flexible transparent material, which is hung, by means of elastic fastenings, from a frame, round the upper edges of the vaporising chamber, so as to extend upwards above the edge of the chamber, to prevent the escape of air laden with vapours over the edge, and, at the same time, owing to its flexibility, to allow of its being depressed easily at any point, where it is necessary to gain access to the chamber for any slight repair, &c. —W. C. H.

Furnace; Reverberatory ——. M. Cummings, Boston, Mass. U.S. Pat. 819,043, May 1, 1906.

THE bridge-wall of the furnace is made hollow and the air-space so formed communicates below with the ash-pit and, at the ends of the bridge-wall, with passages formed in the side walls of the furnace. Air passes from the ash-pit up through the hollow bridge-wall into the passages in the side walls of the furnace and from the latter, which extend above the level of the top of the bridge-wall, the air is delivered into the furnace-chamber through ports placed slightly to the rear of the bridge-wall.—W. H. C.

Furnaces; Application of heat in metallurgical and other ——. B. E. Eldred, Brooklyn, Mass., Assignor to Combustion Utilities Co., New York. U.S. Pat. 819,045, May 1, 1906.

A MIXTURE of air with products of combustion is passed through the ignited fuel on the grate of the furnace and the resulting "tardily-burning" gas is delivered into the heating-chamber above the material being heated, the combustion being completed by radiation from the furnace walls. The materials treated are passed continuously through the heating chamber.—W. H. C.

Furnaces; Means for controlling gas velocity in reverberatory — . B. E. Eldred, Bronxville, N.Y., Assignor to Combustion Utilities Co., New York. U.S. Pat. 819,046, May 1, 1906.

THE claim is for a reverberatory furnace with a long hearth-chamber, through which the materials to be treated are moved mechanically. A number of separate fire-boxes deliver the heating gases into the hearth-chamber, through ports spaced successively along its length. The cross-sectional area of the chamber is successively increased after each inlet by raising the roof-wall, and horizontal baffle-plates or "septa" are placed above each inlet. The fire-boxes are separately fed with a mixture of air and waste gas drawn from the stack for the purpose.—W. H. C.

Separating residues from liquids; Apparatus for ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 819,664, May 1, 1906.

A TANK containing the liquid has two series of partition walls, extending upwards and downwards respectively, and varying in height or depth according to their distance from the inlet and outlet. Scrapers, which move transversely or parallel with the partitions, remove the residues from the top of the liquid.—R. L.

Evaporating liquids; Method of ——. A. P. Geer, New London, Conn. U.S. Pat. 819,697, May 1, 1906.

THE liquid is strongly heated just below the level of the surface and less strongly at a lower level, in order that the liquid near the surface may be evaporated, and that the portion below may be concentrated. The concentrated liquid is drawn off from below, and the volume of liquid in the apparatus is maintained constant by feeding in fresh liquid near the surface in sufficient quantity to compensate both for that withdrawn, and for the water evaporated.—W. H. C.

Gases; Process and apparatus for separating mixed ——. C. Clamond, Paris. U.S. Pat. 820,283, May 8, 1906.

SEE Fr. Pat. 346,195 of 1904; this J., 1905, 78.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 467.)

Powdered coal firing for steam boilers. G. C. McFarlane. Eng. and Mining J., 1906, **81**, 901—902.

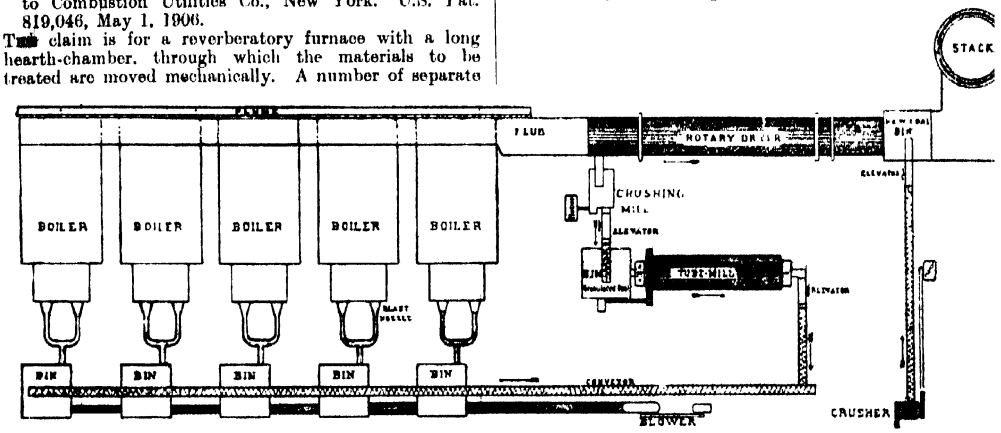


FIG. 1.

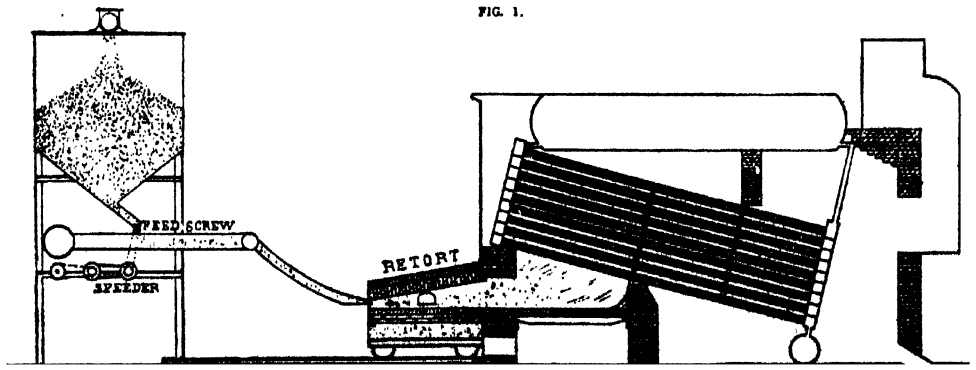

FIG. 1 shows the general arrangement of a fuel mill and boiler room where powdered coal is employed. The coal is first crushed by toothed rolls and then passes through a large rotary dryer heated by the chimney gases from the boilers, or, in the case of small plants, through a small hand-fired dryer. The dried coal is crushed to the size of granulated sugar in a suitable mill, and then further ground in a tube-mill until 95 per cent. will pass a 100-mesh sieve. The apparatus for burning the powdered coal is shown in Fig. 2. The coal-dust is fed into the blast-pipe by a 4-in. screw conveyor, and air is supplied by a Buffalo blower. The blast-pipe consists of a 10-in. rivetted sheet-iron pipe, which, at a distance of a few feet from the boiler, branches into two 7-in. pipes capped with nozzles having orifices 20 in. wide by 1½ in. deep. A fire-brick retort or combustion chamber, from 5 to 8 ft. long, is arranged in front of the boiler. About 145 cb. ft. of air are required to burn 1 lb. of coal, and the chimney gases contain from 1 to 1½ per cent. of free oxygen. It is stated that when coal is burnt in the form of dust, ½ lb. less is required per h.p. hour, than when it is burnt in the usual manner. The following comparison of the cost of hand firing and powdered coal firing is given:—

Hand firing.

Daily expense.	Dols.
65 tons of coal at 2.4 dols.	156.00
Labour	13.60
	169.60
Yearly expense, 320-day run	54,272.00

Powdered coal firing.

Daily expense.	Dols.
58 tons of coal at 2.4 dols.	139.20
Labour	8.32
	147.52
Yearly expense	47,206.40
Amortisation	2,500.00
Interest, 6 per cent. on 15,500 dols. ..	930.00
Repairs, oil, &c.	800.00
	51,436.40

—A. S

Coal-gas and air; Explosions of ——. B. Hopkinson. Roy. Soc., Proc., 1906, A. **77**, 387—413.

THE author has studied the phenomena occurring in a mixture of coal-gas and air, contained in a closed vessel and ignited at one point by an electric spark. The experiments were directed principally to settling the question of "after-burning," which has long been a matter of controversy in the theory of the gas-engine. The apparatus used consisted of a cylindrical vessel of a capacity of 6·2 cb. ft.; the gaseous mixture was ignited in the centre; the temperatures and rate of variation of temperature were ascertained by observing the variation of electrical resistance of fine platinum wires immersed in the gas at different points; and the pressures were observed simultaneously. The gaseous mixtures, which consisted of 9 vols. of air to 1 vol. of coal-gas, and 12 vols. of air to 1 vol. of coal-gas, were ignited at atmospheric pressure. From the results obtained, the author concludes that, even in the weakest mixtures, combustion, when once initiated at any point, is almost instantaneously complete. The specific heat of the products of combustion he finds to be very much greater at high temperatures than at low, the average value of γ (ratio of specific heats) being 1·25 between 1200° and 1900° C. This difference in specific heat is sufficient to account for the so-called "suppression of heat," which has been supposed to be due to the attainment of maximum pressure before the combustion of the gas was complete. No evidence of after-burning was obtained. An increase in specific heat has been observed in the case of carbon dioxide, which has been examined up to about 800° C. The author considers that in gas-engine practice, although the conditions prevailing are somewhat different from those in the apparatus employed, the working fluid may be regarded simply as a mixture of carbon dioxide, steam and inert gas, in chemical equilibrium, to which the heat of combustion, less a small percentage of loss, is added at the beginning of the stroke.—H. B.

Hydrocarbons and oxygen; Interaction of well-dried mixtures of ——. W. A. Bone and G. W. Andrew. Chem. Soc. Trans., 1906, **89**, 652—659.

Two similar tubes containing respectively, thoroughly dried, and undried, equimolecular mixtures of a hydrocarbon (acetylene, ethylene, ethane) and oxygen, were heated under similar conditions for the same length of time, comparative experiments being also made with electrolytic gas, dried and undried, in order to ensure that the degree of dryness attained was such as would practically inhibit the combustion of hydrogen. It was found that the exclusion of moisture had little, if any, influence on the rate of oxidation of the hydrocarbons.—A. S.

Hydrocarbons; Explosive combustion of ——. W. A. Bone and J. Drugman. Chem. Soc. Trans., 1906, **89**, 660—682.

THE authors have made a systematic study of the explosive combustion of a number of different gaseous hydrocarbons, including members of the saturated series, C_nH_{2n+2}, up to butane, olefines such as ethylene, propylene and the butylenes, and trimethylene and acetylene. The term "explosive combustion" is used to denote the propagation of a flame through a combustible mixture under ordinary conditions. In the case of mixtures containing sufficient oxygen to completely convert the hydrocarbon into carbon monoxide and hydrogen, there is a considerable difference between the behaviour of an unsaturated and a saturated hydrocarbon. The mixtures containing an olefine, or acetylene, or trimethylene, decompose chiefly into carbon monoxide and hydrogen, according to the empirical equation:

$$C_nH_{2n} + \frac{n}{2}O_2 = nCO + nH_2;$$

there is no separation of carbon, and very little, if any, formation of steam. With the mixtures containing a paraffin, on the other hand, there is always a considerable separation of carbon, and formation of steam, whilst the gaseous products contain, besides carbon monoxide and hydrogen, between 8 and 10 per cent. of methane, and appreciable quantities of unsaturated hydrocarbons and carbon dioxide. If the proportion of oxygen in the mixtures containing an olefine or trimethylene, be diminished, then on combustion, much water, as well as carbon is produced, the amount of water increasing as the supply of oxygen is reduced. When acetylene is burnt in the presence of a deficient supply of oxygen, however, no appreciable quantity of water is produced; part of the acetylene is burnt to carbon monoxide and hydrogen, and the remainder is decomposed into carbon and hydrogen, together with a small quantity of methane. Comparative experiments showed that mixtures of paraffin hydrocarbons and oxygen, and mixtures of corresponding olefines or acetylene with hydrogen and oxygen in proportions necessary to yield mixtures of the same ultimate composition as the paraffin mixtures, gave entirely different results on explosive combustion. As stated above, there is a considerable separation of carbon and formation of steam with the mixtures containing a paraffin, whereas with the mixtures containing an olefine or acetylene and hydrogen, no carbon separates and very little steam is formed.

The authors have succeeded in detecting the presence of aldehydes among the products of the explosive combustion of hydrocarbons, and also, in minute quantities, in the interconal gases obtained by means of a Smithell's flame-separator, in which either ethane or ethylene was being burnt, and among the products of an oxygen flame burning in an atmosphere of ethylene or of coal-gas.

The results of the present investigation are stated to show conclusively that the theory of the preferential

combustion of carbon must be discarded. There appears to be no essential difference between the mechanism of combustion below and above the ignition point, the first step in each case being the formation of an "oxygenated" molecule from the molecules of hydrocarbon and oxygen (see Chem. Soc. Trans., 1902, **81**, 536; 1903, **83**, 1074; 1904, **85**, 693, 1637; 1905, **87**, 1232; this J., 1901, 696; 1904, 601, 629; 1905, 792, 1005). Taking into consideration the results obtained in the previous paper (see preceding abstract), the authors consider that in the combustion of hydrocarbons, oxygen acts directly, rather than through the intervention of steam, as suggested by H. E. Armstrong (this J., 1905, 473). The explosive combustion of a typical olefine—propylene - may be represented as follows:—

$$CH_3.CH:CH_2 \xrightarrow{(1)} CH_3.CH:CH(OH) \xrightarrow{(2)} CH_2:CH_2 + CH_2O$$

$$CO + H_2$$

$$\xleftarrow{(3)} CH_2:CH(OH) \xrightarrow{(4)} CH(OH):CH(OH)$$

$$2CH_2O = 2CO + 2H_2$$

If the supply of oxygen be limited, the process might go as far as stage (3), and then the hydroxy compound, $CH_2:CH(OH)$, would break down into acetylene and water, or carbon, hydrogen and water. In the case of the paraffins, the decomposition may proceed according to the following scheme:—

$$CH_3.CH_2.CH_3 \rightarrow CH_3.CH_2.CH_2(OH) \rightarrow CH_3.CH_2.CH(OH)_2$$

$$CH_3.CH_2.CHO + H_2O$$

the aldehyde then being decomposed with production of carbon monoxide and a lower paraffin, which latter is, in turn, decomposed in a similar manner; or, the primary oxidation product, $C_nH_{2n+1}OH$ may decompose into steam and an olefine, the latter being then burnt in its own peculiar way. The end result would be the same in both cases.—A. S.

English Patents.

Gas for illuminating, heating or power purposes; Manufacture of —. H. S. Elworthy, St. Albans, and E. H. Williamson, London. Eng. Pat. 7713, April 11, 1905.

In the manufacture of gas rich in methane, according to the processes described in Eng. Pats. 12,461 of 1902, and 14,333 of 1904 (this J., 1903, 900; 1905, 1006), the gaseous mixture, either before or after treatment with metallic nickel, is mixed with a considerable excess of hydrogen or methane. The gas produced may be passed through retorts wherein coal is undergoing distillation, or may be mixed in any desired proportion with coal gas or other combustible gas.—H. B.

Gas producer. T. W. S. Hutchins, Blackpool. Eng. Pat. 11,657, June 3, 1905.

The producer, which is designed to be used as a suction apparatus with bituminous fuel, has a rectangular combustion chamber divided, up to a suitable height, into two chambers by means of a vertical mid-feather of refractory material. On the top of the latter rests an iron pipe, serving as vaporiser, which extends through the shell of the producer, water being admitted along with air at one end, whilst the other communicates with a valve, by means of which the mixture of air and steam may be admitted alternately to the lower regions of the two chambers. The gases thus pass up on one side of the mid-feather and descend on the other to the outlet at the base. The direction of the gases is reversed periodically by means of an automatic device, consisting of a two-chambered tilting tank, into which water flows continuously, the oscillations of the tank, as the chambers alternately fill with water, effecting the simultaneous reversal of the inlet and outlet valves.—H. B.

Gas from carbonaceous materials; Manufacture of —. G. Wilton, London. Eng. Pat. 25,275, Dec. 5, 1905.

The gas entering the hydraulic main, is caused to pass directly through a current of cooled gas-liquor kept constantly flowing through the main, for the purpose of increasing the cooling effect and the deposition of the tar.—H. B.

Gas analysis; Apparatus for use in —. C. A. Hartung. Eng. Pat. 17,708, Sept. 1, 1905. XXIII., page 561.

Filaments for electric incandescent lamps. E. L. Frenot, Paris. Eng. Pat. 8891, April 27, 1905. Under Int. Conv., May 7, 1904.

See Fr. Pat. 344,759 of 1904; this J., 1904, 1206.—T.F.B.

Incandescence lamp with filament of metallic tungsten; Electric —. W. P. Thompson, London. From Deutsche Gasglühlicht Akt.-Ges. (Auergas.), Berlin. Eng. Pat. 18,814, Sept. 18, 1905.

See Fr. Pat. 357,868 of 1905; this J., 1906, 116.—T. F. B.

United States Patents.

Fuel; Apparatus and process for the combustion of pulverulent —. A. Moore, Portland, Colo. U.S. Pat. 820,235 and 820,236, May 8, 1906.

The pulverulent fuel is supplied to the combustion-chamber through a tube, which is surrounded by an annular jacket. The annular space is divided by partitions into a number of passages through each of which a separately controlled supply of air or other fluid supporter of combustion is admitted under pressure. By varying the ratios of the pressures under which the air is supplied through the different air passages, the jet or current of pulverulent fuel may be directed towards any desired point in the combustion-chamber.—W. H. C.

Gas-producer. E. N. Trump, Syracuse, N.Y. U.S. Pat. 813,600, Feb. 27, 1906.

The producer, which is of the blast type, has a stationary base-plate, separated from the lower end of the combustion chamber by an interval sufficient to admit of the rotation, in a horizontal plane, of a radial scraper, or ash-deflector, which slowly sweeps over the surface of the base plate, expelling the ash at its circumference, and, on account of the subsidence of the fuel in the track of the scraper, causing a continual disturbance of the whole bed of fuel. In this way clinkering is prevented. The outer end of the scraper is supported by a ring which surrounds the lower end of the producer and is caused to rotate slowly by an electric motor. To ensure the uniform distribution of the fresh fuel, the feed hopper is provided at its lower end with a horizontal plate, separated from the hopper by an interval sufficient to admit of the rotation of a series of rotating arms, which sweep the fuel over the edge of the plate.—H. B.

Gas generating machine. O. V. Monroe, Assignor to General Patent Promoting Co., Portland, Oreg. U.S. Pat. 819,074, May 1, 1906.

The gas generator consists of a tank divided into three compartments. The upper compartment serves as a storage reservoir, the lower compartment as an air-chamber, and the intermediate compartment as a carburettor. The bottom of the carburettor has a central aperture over which a hood in the form of a truncated cone is secured. The air-inlet pipe passes through the opening in the upper part of the hood. A suitable valve controls the admission of air through this pipe. A gas outlet is provided on the carburettor, which is connected with the storage reservoir by a vent pipe and by a feed pipe. The reservoir end of this latter pipe is covered with a screen and protected by a dam in front of it. A vaporiser within the carburetting chamber consists of a disc with a central aperture over which a conical hood is fitted covering the air inlet. An inverted conical member within this hood holds a guide-rod in position which leads into the air inlet pipe. Channels are formed by partitions depending from the disc and baffle-plates are provided in these channels. An annular float surrounds the disc at its periphery, which is adjustably secured to the disc. The disc is covered by a roof fitted on the conical hood.

—R. L.

Gas producer. C. H. Morgan, Worcester, Mass. U.S. Pat. 819,075, May 1, 1906.

THE chamber of a gas producer has a cover and a tuyère depending from the cover, a rotating sleeve being fitted round the tuyère and moving concentrically with the axis of the chamber by means of an internal gear and pinion. The fuel is admitted through an opening in the cover, eccentric to the axis, and the top of the fuel is levelled by a scraping blade fixed tangentially to the sleeve and projecting beneath the opening in the cover. —R. L.

Hydrocarbon and combustible gas; Process of making ——. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 819,506, May 1, 1906.

HYDROCARBONS are produced by exposing a gaseous mixture of ketones and steam to the action of heat. Thus, methane is formed by the treatment of acetone or dimethyl-ketone. A combustible gas is produced by exposing a mixture of a ketone and superheated steam to the action of incandescent carbon.—R. L.

Gas; Method of manufacturing ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 819,661, May 1, 1906.

THE process consists in burning oil and passing the highly heated products of combustion successively through two chambers filled with loosely-piled refractory material, thus highly heating the same, then shutting off the air and fuel, and passing, in the opposite direction, steam through both chambers and hydrocarbonaceous material through the second chamber to make gas. The gas-making steam and hydrocarbons are then shut off, and air is admitted to burn off the coke deposited from the hydrocarbons. The gas resulting therefrom is used again in heating the refractory material. Or else, the gas produced in the coking operation may be used for heating, and the gas made in burning off the coke may be added to the gas produced from the oil. —R. L.

Gas-making apparatus. L. P. Lowe, San Francisco, Cal. U.S. Pat. 819,662, May 1, 1906.

IN this gas-making apparatus a gas generating chamber, furnished with loosely-piled refractory material, is combined with a coking and combustion chamber at the gas-outlet end, the outlet pipe leading from the top of the combustion chamber. Means are provided to admit oil and air to the combustion chamber and to admit steam and oil to the generating chamber, and to close each of these inlets independently, as well as a flue and auxiliary flue on the end of the generating chamber opposite the gas outlet. Carbonaceous material can be charged into the lower portion of the combustion chamber through a door independent of the oil inlet, the combustion chamber having a transverse wall, against which the flames of the burning oil impinge. (See preceding abstract.)—R. L.

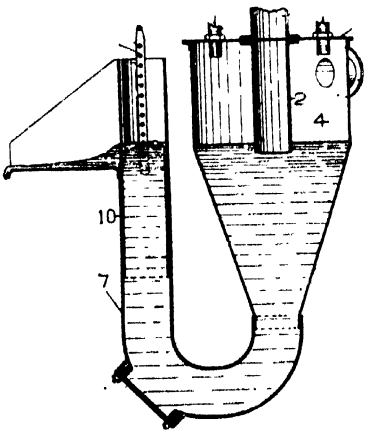
Coking and making gas; Method of ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 819,663, May 1, 1906.

THE method of simultaneously coking and making gas consists in charging hydrocarbonaceous material into a coking chamber, then admitting oil and air into this chamber, and burning the oil above the hydrocarbon, whilst at the same time a body of refractory material is heated and the carbonaceous material partly coked. The air supply is then shut off, but the admission of oil continued, and the vapours of the oil, together with the vapours produced from the hydrocarbons, are passed through the refractory material to make gas.—R. L.

Gas; Apparatus for generating ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 819,666, May 1, 1906.

A WALL extending from the top to a point near the bottom divides the gas generator centrally. An upper and a lower pile of regenerative material are placed on each side of this wall. The generator is furnished with a fluid-fuel inlet at each side above the lower pile, a gas outlet and fluid-fuel inlet below all the regenerative material, a steam inlet at each side above the upper pile, a flue for the products of combustion at each side of the top, and an air-blast conduit for conducting air to the top at each side, the flues and conduits being controlled by suitable valves.—R. L.

Furnace [Gas producer]. F. W. Burger, Assignor to Fort Wayne Foundry and Machine Co., Fort Wayne, Ind. U.S. Pat. 819,849, May 8, 1906.

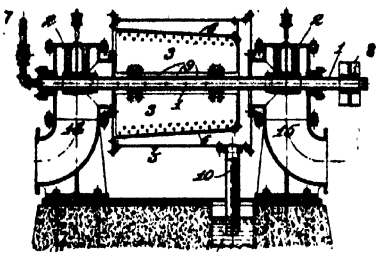


THE "fire-pot" of a gas-producing furnace is surrounded by a chamber into which moisture is introduced through a pipe, and which is connected by another pipe to the ash-pit. Air is introduced beneath the grate by a pipe or "air-duct" terminating in the ash-pit.—W. H. C.

Gas-purifying apparatus. A. M. Gow, Edgewood Park, Pa., Assignor to G. Westinghouse, Pittsburg, Pa. U.S. Pat. 815,812, March 20, 1906.

WITHIN a horizontal casing, the bottom of which is open and rests in a water tank, there extends a rotatable shaft carrying, at right angles to its axis, a number of dirt-collecting devices, which rotate with the shaft, and alternate with series of stationary, radially-fixed vanes. Each dirt-collector is built up of a number of blades, bent over along one edge. A stream of water, and the gas to be cleansed, are admitted at one end of the casing; the water is broken up into spray by the first revolving dirt-collector; the solid particles of dirt, becoming wet, are caught by the bent-over edges of the blades and impelled centrifugally to the periphery, finding their way to the water tank below; whilst the gas, on passing from the first collector, is guided by the stationary vanes in the proper direction against the second dirt-collector, and so on.—H. B.

Gas-washer. L. P. Lowe, San Francisco, Cal. U.S. Pat. 819,660, May 1, 1906.



THE gas-washer proper, 4, is provided with a water-inlet pipe, and has a conical lower portion. It is connected

at the bottom to a water-outlet pipe, 7, which has the form of an inverted siphon. In the rising limb of the water-outlet pipe is a pipe, 10, which can be moved up and down, and the position of which is so adjusted that the discharge of the water can take place only at a point above the level of the bottom of the gas-supply pipe, 2. —A. S.

Gas; Machine for cleaning —— *[from tar and solid matter].* C. O. Nordensson, Scane, Sweden, Assignor to J. A. Laird, St. Louis, Mo. U.S. Pat. 820,247, May 8, 1906.

A HOLLOW shaft, 1, having radial perforations, 9, and beater-blades, 3, is mounted in the journals, 2, and can be rotated by the pulley, 8. The blades are surrounded by a conical perforated casing, 6, and by an outer casing, 5. The hollow shaft has an inlet pipe, 7, and the outer casing,

5, has a sealed drain pipe, 10. The gas enters through the pipe, 14, into the interior of the perforated casing and escapes through the pipe, 15, at the other end.—W. H. C.

Carbide; Manufacture of ——, *also of superheating compound for use therein, and of a lining for the electric furnace.* H. L. Hartenstein, Assignor to Electro Chemical and Development Co. U.S. Pats. 819,218–819,223, May 1, 1906. XIA., page 544.

FRENCH PATENTS.

Gas for lighting, heating and power purposes; Manufacture and composition of ——. H. S. Elworthy. Fr. Pat. 360,902, March 17, 1905.

SEE Eng. Pat. 7713 of 1905; preceding these.—T. F. B.

Gas from heavy oils, for operating motors; Producer for production of permanent ——. J. E. M. Briest. Fr. Pat. 360,541, Dec. 16, 1905.

THE exhaust outlets from the cylinders of an explosion motor are connected to a common exhaust pipe, in the walls of which are cast or bored a series of channels. Into the latter the oil is fed, encountering a current of air which is drawn in simultaneously, permanent gas being produced from the mixture as it passes through the hot channels on its way to the cylinders. On starting the motor, the exhaust pipe may be heated beforehand by means of a burner, or the engine may first be driven by petrol until the channels in the exhaust pipe have become hot enough.—H. B.

Carburetting apparatus for the production of [*air-*] *gas for lighting or heating.* L. Robert. Fr. Pat. 360,677, Dec. 19, 1905.

AIR is driven by a meter-drum, the rotation of which is caused by a falling weight, into a floating-bell gas holder, and passes thence through zig-zag passages in a carburetting box containing volatile hydrocarbon. In order that the production of gas may not cease during the periodical winding up of the small drum, on which is wound the cord of the falling weight, a loose pinion wheel and spring catch device is provided, enabling the meter-drum to remain stationary during the re-winding, the floating bell maintaining the supply of air in the meanwhile.—H. B.

Gases; Apparatus for the [*automatic*] *analysis of* ——. "Monopol" Betriebs-kontroll-Apparate, K. Steinbock. First Addition, dated Nov. 28, 1905, to Fr. Pat. 359,352, Nov. 2, 1905 (this J., 1906, 394). Under Int. Conv., April 12, 1905.

IMPROVEMENTS in the constructional details of the apparatus referred to in the principal patent are here described.—H. B.

Purifier for [*blast furnace*] *gases.* E. Weisse and C. Kieselbach. Fr. Pat. 360,720, Dec. 20, 1905.

WITHIN a vertical casing, upwards through which the gases flow, is arranged a number of vertical pipes, each containing a helical blade, forming a helical passage for the gases throughout the length of the pipe. The gases, on flowing upwards through each pipe, are thus given a whirling motion, the particles of dust, &c., being impelled centrifugally against the perforated walls of the pipe, where they meet with currents of water, which trickles down the interior and exterior of the pipes, and carries the impurities off to the bottom of the casing. Two tiers of pipes may be arranged within the casing, the pipes in the lower tier, through which the gases first pass, being irrigated with water, for the removal of the dust, &c., whilst the upper pipes, serving merely to retain the water-spray carried off from the lower tier, are not irrigated, but have perforated walls through which the intercepted water may pass off.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 468.)

Petroleum industry of Texas. For. Off. Ann. Series, No. 3585.

THE petroleum industry of Texas has been of growing importance during the last few years. Texas produced 30,404,203 barrels of 42 galls. each of crude petroleum in 1905—the greatest yield of oil ever credited to a single State in a year. Texas was second in 1904 with 22,241,413 barrels. All but 595,306 barrels of the output came from the Gulf coast districts in the south-eastern part of the State. The production of the Corsicana and Clay County fields, 417,255 barrels, represents the total light oil output in Texas. All of the Corsicana product and 66,160 barrels of the Clay County oil went to the refineries. Oil testing 28° B. is found at Powell and at Batson, one of the south-east Texas districts. Most of the south-east Texas oil, however, tested 20° to 24° B.

The great increase in south-east Texas production resulted from the unprecedented output at Humble, the Harris County district, where a 7000-barrel gusher, brought in on January 7, started development on a big scale. Several wells have yielded nearly 1,000,000 barrels each. During the 12 months of 1905 the Humble field produced 18,066,428 barrels of oil, excluding 75,000 barrels of inferior product, making a total gross output of 18,141,428 barrels for the year. Batson, which produced 10,904,737 barrels in 1904, dropped to 3,790,628 barrels in 1905. Sour Lake made 3,369,012 in 1905, and Spindle Top, now five years old as an oil field, produced 1,600,378 barrels.

Rail consignments of south-east Texas oil in 1905, representing consumption as fuel by railroads, power plants and other industries in Texas, amounted to 7,881,550 barrels, as against 7,067,673 barrels in 1904.

Shipments of crude oil from Port Arthur and Sabine in 1905 amounted to 6,595,706 barrels, against 10,031,459 barrels in 1904. The south-east Texas refineries increased their runs very largely, handling 7,000,000 barrels.

[T.R.]

ENGLISH PATENT.

Wood tars and resin oils; Distillation and oxidation of ——. H. Noordlinger, Floersheim on the Maine, Germany. Eng. Pat. 8590A, Sept. 15, 1905.

THE process described in Ger. Pat. 166,350 of 1903 (this J., 1906, 367) for the oxidation of beech-wood tar, is applied to the oxidation of all kinds of wood tars and resin oils to form alkali-soluble products.—T. F. B.

UNITED STATES PATENT.

Ammonia from gas; Process of recovering ——. E. J. Duff, Liverpool. U.S. Pat. 820,039, May 8, 1906.

SEE Fr. Pat. 352,180 of 1905; this J., 1905, 884.—T. F. B.

FRENCH PATENT.

Ammonia derived from the carbonisation of coal; Uniform process for the recovery of ——. W. Feld. Fr. Pat. 360,528, Dec. 15, 1905. Under Int. Conv., Dec. 15, 1904.

IN order to recover ammonia from the gases in a purer

and more concentrated form, the tar and water are successively condensed out at a temperature exceeding 40° C., whereby they are eliminated without retaining an appreciable quantity of ammonia, and the gases are then scrubbed with appropriate quantities of water, at about 20° C., or with solutions of salts, such as magnesium chloride, at 40°—60° C. Preferably the hot crude gases are first treated, at 100°—200° C., with a spray of hot tar, and are then washed with a more liquid substance, such as tar oil, to remove the last traces of tarry mist. The gases, having a temperature which may be between 40° and 150° C., are next treated with a spray of hot water containing a little milk of lime. This condenses the water mist, without retaining an appreciable quantity of ammonia, any non-volatile ammonium salts being decomposed by the lime. The gases are then scrubbed directly with the salt solution, or, if they are to be scrubbed with pure water, they are first cooled to about 20° C.

—H. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 472.)

Nitrophenols; Constitution and colour of ——. G. v. Georgievics. Ber., 1906, **39**, 1536—1538.

Aqueous solutions of picric acid, when heated, become darker. On cooling, the original colour reappears Alcoholic solutions behave similarly, although the change is not so marked. The author concludes that picric acid is capable of existing in two modifications. Two dyebaths were prepared with equal quantities of wool, picric acid, water and sulphuric acid. In one case, dyeing was done in the cold. The other dyebath was heated in the usual way. Both were then allowed to stand for a few days, until the exhaust liquors were found to be equal in strength, and the wool was then examined in a Wolff's colorimeter. The wool which had been dyed cold was of a much lighter shade than that which had been first dyed at the boil. On boiling with water for some time, it became just as dark as the other sample. A portion of the picric acid, it is said, must have been taken up in a less deeply coloured modification, which is converted into the darker form by boiling with water.—H. L.

Anüline-sulphonic acids; Acylation of ——. G. Schroeter. Ber., 1906, **39**, 1559—1570.

The authors prepared acetylnaphthionic acid, acetyl-1.5-naphthylaminesulphonic acid, benzenesulphosulphanilic acid ($C_6H_5SO_2.NH.C_6H_5.SO_3H$) and benzenesulphonaphthionic acid ($C_6H_5SO_2.NH.C_{10}H_6.SO_3H$1:4). These substances do not in general combine with diazo compounds, to form true azo bodies, but yield coloured, well crystallised diazonium salts with diazotised nitranilines, benzidine, and α-naphthylamine. Diazotised *p*-nitraniline, however, behaves exceptionally, and may be combined with benzenesulphosulphanilic and benzenesulphonaphthionic acids to form true azo compounds which dye wool in yellow and orange shades respectively. The chlorides of the above acylamino-sulphonic acids can be prepared by triturating the sodium salts with phosphorus pentachloride; they are stable, well characterised substances. By condensing benzenesulphosulphanilic acid chloride and benzenesulphonaphthionic acid chloride with cellulose, and then coupling them on the fibre with *p*-nitrophenyldiazonium acetate, the authors endeavoured to produce cellulose esters of the corresponding azo dyestuffs. Thus cotton was treated for some time under a reflux condenser with a boiling chloroform solution of benzenesulphosulphanilic acid chloride, m. pt. 177° C., containing a little pyridine. After being thoroughly washed first with chloroform, then with water, the cotton was found to contain 2·77 per cent. of sulphur. It was dyed yellow after development with diazotised *p*-nitraniline. Similarly mercerised cotton treated with a chloroform solution of benzenesulphonaphthionic acid chloride, m. pt., 171° C., and developed with diazotised *p*-nitraniline was dyed orange brown.—H. L.

Methylene Azure; Chemical nature of ——. A Bernthsen. Ber., 1906, **39**, 1804—1809.

The author confirms the recently published work of Kehrmann (see Ber. **39**, 1403; this J., 1906, 469), who showed that "Methylene Azure" is a mixture of dimethyl- and trimethyl-thionine. Methylene Azure was first obtained by Bernthsen (see Annalen, **230**, 169) by heating Methylene Blue base with alkalis. A better yield may be obtained by oxidising Methylene Blue with potassium bichromate and dilute sulphuric acid.—H. L.

1.4-*Anthraquinone.* K. Lagodzinski. Ber., 1906, **39** 1717—1718.

The author claims priority with regard to the discovery of the above compound (compare Dienel, this J., 1906, 309). He found shortly after the discovery of α-anthrol by Schmidt (this J., 1904, 182) that the latter formed red azo dyestuffs with benzene-diazonium compounds, from which 1.4-aminoanthrol was obtained by reduction in alkaline or acid solution, and which, in its turn, was converted into 1.4-anthraquinone by oxidation with ferric chloride.—D. B.

α-Naphthoflavonol. G. Woker. Ber., 1906, **39**, 1649—1653.

α-Naphthoflavanone,

$$C_{10}H_6\!<\!\begin{matrix}O\text{—}CH.C_6H_5\\ CO.CH_2\end{matrix}$$

was obtained by boiling the chalkone,

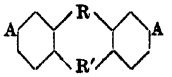
$$(HO)C_{10}H_6.CO.CH{:}CH.C_6H_5$$

in alcoholic solution with hydrochloric acid. It crystallises from alcohol in colourless needles, exhibiting a bluish-violet fluorescence and melting at 126° C. When treated with amyl nitrite and hydrochloric acid, it is converted into the isonitroso derivative, which forms yellow leaflets melting at 173°—174° C., and yields α-naphthoflavonol,

$$C_{10}H_6\!<\!\begin{matrix}O\ .\ C.C_6H_5\\ CO.C(OH)\end{matrix}$$

when boiled with a mixture of acetic and dilute sulphuric acids. The latter compound crystallises from alcohol in green leaflets, which melt at 210° C. The sodium salt is coloured intensely yellow and is only sparingly soluble in water; the acetyl derivative crystallises in lustrous laminæ, melting at 194°—195° C. The authors have effected a second synthesis of α-naphthflavone from the above flavanone by replacing a hydrogen atom in α-position by bromine, and treating the product in alcoholic solution with potassium hydroxide.—D. B.

Thio Indigo Red; a new synthetic dyestuff. E. Knecht. J. Soc. Dyers and Colourists, 1906, **22**, 156—159.



The author describes the preparation and method of using Thio Indigo Red (see this J., 1906, 367; also Fr. Pats. 359,398, 359,399 and 359,400; this J., 1906, 424, 426). This new dyestuff is more readily affected by reducing agents than indigo, but it and its leuco compound are more resistant to oxidising agents than Indigo and Indigo White. Cotton "bottomed" with Thio Indigo Red, and then treated in an Indigo vat containing a slight excess of hydrosulphite, is dyed an almost pure shade of indigo, practically all the red being "stripped." By "bottoming" first in the hydrosulphite vat with Thio Indigo Red, and then "topping" in the zinc vat with indigo, the author states that he obtained very promising effects. For instance, cotton "bottomed" with only a light shade of the new dyestuff, and then treated in an ordinary zinc indigo vat along with a piece of untreated white cotton, was dyed a blue of about (apparently) double the intensity of that shown by the plain cotton.

If cotton dyed a fairly heavy shade with Thio Indigo Red be immersed in concentrated nitric acid, the blue shade changes to a yellow shade of red, whilst the cotton is at the same time mercerised.—A. S.

Dyestuffs; Fluorescence of ——. J. Formánek. Z. Farben-Ind., 1906, **5**, 142—146; 164—169.

The author considers that, in most cases, fluorescence is shown in aqueous, alcoholic or amyl alcohol solution,

only by those dyestuffs which can be derived from the type:

where R represents oxygen, sulphur or nitrogen, and R′ carbon or nitrogen, whilst AA are auxochrome groups in the para position to the fundamental element or atomic group. If the auxochrome groups are amino groups, the hydrogen atoms of these may be replaced by alkyl or benzyl radicals without the fluorescence being destroyed. The benzene rings may be replaced by naphthalene or phenanthrene nuclei. The fluorescence is influenced by the nature of atoms or atomic groups connected directly to the benzene rings, and also by the solvent used.—A. S.

Indigo; Java ——. For. Off. Ann. Series, No. 3580.

The planting of indigo has still further diminished: in fact, many of the lands on which indigo has hitherto been cultivated have now been turned into sugar plantations. Japan and Russia, the two largest consumers of Java indigo, have not taken anything like the quantities which they did in previous years. There is still a considerable quantity used locally for the native dyeing industry, but the future is not looked forward to hopefully Exports for the past three years were:—1903, 1,297,274 lb.; 1904, 1,070,601 lb.; 1905, 540,452 lb. [T.R.]

Dyewood trade of Havre. For. Off. Ann. Ser., No. 3586.

The importations of dye woods in 1905 showed a further decrease from 1904 in logwood and yellow woods. The logwood import amounted to 33,143 tons, against 45,515 tons in 1904 and an average of 49,703 tons in the five years 1900—04. Of yellow woods only 2906 tons were imported, against 7640 tons in 1904 and an average of 8645 tons in the five years 1900—04, and of red woods 1191 tons were imported, against only 419 tons in 1904, and an average of 965 tons in the previous five years. Of the logwood 24,008 tons came from Haiti, 966 tons from San Domingo and 4,890 tons from Jamaica. The amount of quebracho wood imported was 10,044 tons, against 22,075 tons in 1904 and an average of 18,460 tons in the five years 1900—04. [T.R.]

Dyestuff and process of making same; Anthracene ——. O. Bally and M. H. Isler, Mannheim, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 820,379, May 8, 1906.

See Sixth Addition, of June 22, 1905, to Fr. Pat. 349,531 of 1904; this J., 1906, 14.—T. F. B.

Lakes from sulphide dyestuffs; Process for producing fast ——. L. Cassella und Co. Fr. Pat. 360,825, March 13, 1905. XIIIA., page 546.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 475.)

Cotton; Insects which attack ——. *in Egypt.* G. C. Dudgeon. Bull. Imp. Inst., 1906, **4**, 48—52.

The most destructive insect pest in Egypt is the boll worm, *Earias insulana*, which has reduced the yield of many plantations by as much as 75 per cent. It also feeds on varieties of *Hibiscus* and on "volunteer cotton." The elimination of the pest clearly lies in the destruction of all *Hibiscus* and "volunteer cotton" at a time when the cotton stalks have been uprooted and dried. The cotton worm does much harm, to cotton and "berseem," in many districts. Preventative measures against this worm consist in preparing the soil as long as possible before sowing, in order to starve out the worms, and the removal and destruction of all leaves on which eggs have been laid. Other insects which do much damage are the cut worm, *Agrotis ypsilon*, the asal fly, *Aphis sorghi*, and the Egyptian cotton stainer, *Oxycarenus hyalinipennis*, but the latter does not seem to attack healthy cotton plants. Locusts have also caused considerable damage during the last two years.—W. P. S.

Fibres from Madras. Bull. Imp. Inst., 1906, **4**, 23—29.

The chemical and physical properties, &c., of six samples of *Agave* and *Furcraea* fibres received from Madras were as follows:—

Paranitraniline Red lake for calico printing; Preparation of ——. P. P. Wicktoroff and N. W. Philippoff. Z. Farben-Ind., 1906, **5**, 182—184.

'A bright Paranitraniline Red lake is obtained by precipitating the dyestuff on a substratum of starch according to the following recipe:—1·5 kilos. of β-naphthol are dissolved in 2·9 kilos. of caustic soda of 20° B., 15 kilos. of castor oil soap, and 10 kilos. of boiling water. This solution is cooled to 6° C., and then poured into a mixture

of 19 kilos. of wheat-starch with 15 kilos. of water. The diazo solution contains 3 kilos. of *p*-nitraniline, 1·8 kilos. of nitrite, 9·2 kilos of hydrochloric acid of 20° B., 10 kilos. of water, 30 kilos. of ice, and 10 kilos. of acetic acid of 6° B. The acetic acid is added to decompose the soap, and precipitate the fatty acid. This solution is filtered and allowed to run slowly into the β-naphthol solution with good stirring. The yield of dry lake is 25·6 kilos., and the cost is stated to be low in comparison with that of competing products on the market. The printing colour consists of 6 kilos. of this lake, 1 kilo. of gum tragacanth solution 1:9, 4 kilos. of blood albumin 2:3, 2 kilos. of olive oil and turpentine mixed in equal proportions, and 600 grms. of formaldehyde-ammonia, prepared from 3 kilos. of 40 per cent. formaldehyde and 2 kilos. of 25 per cent. ammonia. A short steaming is sufficient to fix this colour, as formaldehyde is set free and rapidly coagulates the albumin. After "chloring" the shade is stated to be equal to that of Paranitraniline Red produced on the fibre, but the colour is very loose to rubbing. The authors recommend the lake prepared as above in particular for preparing a red discharge colour on an Indigo Blue ground.—H. L.

Paranitraniline; Red ——. H. Pomeranz. Z. Farben-Ind., 1906, **5**, 184—185.

The author states that the essential point in producing a bright Paranitraniline Red on cloth is that both components, in particular the sodium β-naphtholate, are in solution at the moment of combination. In actual practice, the goods are generally padded with a solution containing β-naphthol (20—25 grms. per litre), rather more than one equivalent of caustic soda, and a quantity of soap. They are then dried in the hot flue, which leaves in them a certain amount of moisture. An excess of alkali is necessary, because sodium β-naphtholate is dissociated in dilute aqueous solution, but a large excess is detrimental, according to the author, because caustic soda salts out sodium β-naphtholate, and thus tends to throw it out of solution at the moment of combination. The beneficial action of a soap is stated to be due to the solubility of β-naphthol in soap. Thus, 50 grms. of fatty acid neutralised with caustic lye and diluted to a litre, will dissolve 25 grms. of β-naphthol at 70°—80° C. On cooling, only about one-fifth to one-sixth of the β-naphthol crystallises out. The author states that a padding solution made up in this way, to which just sufficient caustic soda has been added, to prevent the β-naphthol crystallising out on cooling, yields the best results. Cloth prepared in this way is least affected by steaming. On the other hand, more than the above quantity of fatty acid is deterious to the shade. Castor oil soap is particularly suitable.—H. L.

Azo-dyestuffs; Production of —— in the fibre, and the influence of fats in the process. E. Justin-Müller. Sixth Internat. Congr. of Appl. Chem. Z. angew. Chem., 1906, **19**, 852.

The intensity of the colour depends greatly on whether the fabric, soaked in the naphthol-solution, is dried or not before combination with the diazo solution. The depth of tint depends firstly, on the penetration of the fibre by the β-naphthol derivative, and secondly, on the colloidal condition of the dyestuff. The impregnation of the fibre with soluble fats greatly favours the conversion of the dyestuff into the colloidal state.—J. T. D.

English Patents.

Dyeing and printing Aniline Black; Method of ——. W. Epstein, Frankfort a/Main, Germany (formerly of Shipley, Yorks.). Eng. Pat. 17,315, Aug. 26, 1905.

The fabric is impregnated or printed with a solution of a suitable oxidising agent, and is then exposed to the vapour of aniline or one of its homologues, alone, or diluted with a suitable gas. Cotton may be impregnated or printed with a solution of 2·2 lb. of potassium bichromate and 12 lb. of ferric sulphate in 20 galls. of water, and exposed in a chamber heated to about 130° F., to the action of aniline vapour; it is then passed through a bath made by diluting the first bath with 10 times its volume of water, rinsed, soured, rinsed again, and finally soaped and finished as usual.—T. F. B.

Dyeing fabric; Apparatus for ——. E. A. F. Zillessen, Passaic, U.S.A. Eng. Pat. 2220, Jan. 29, 1906.

Waterproofing composition. J. A. Shepherd, Pollokshields, Glasgow. Eng. Pat. 17,057, Aug. 23, 1905.

A waterproofing composition for fabrics is prepared by mixing together jelly soap, 36 parts; gum tragasol, 32 parts; wax, 7 parts; and water, 37 parts. The composition is "set" in the fabric by passing the latter through a bath containing aluminium sulphate.—T. F. B.

United States Patent.

Silk; Process of charging ——. G. Gianoli, Milan, Italy. U.S. Pat. 819,751, May 8, 1906.

See Eng. Pat. 25,728 of 1904; this J., 1905, 129.—T. F. B.

French Patents.

Silk; Process for the manufacture of artificial ——. P. Germain. Fr. Pat. 360,395, Feb. 22, 1905.

A homogeneous paste is prepared by dissolving nitrocellulose, celluloid and naphthalene in acetone, and adding to the solution powdered barium sulphate. The paste is then spun into threads which are at once immersed in dilute sulphuric acid. This removes the acetone which may be recovered for further use. The excess of acid remaining in the threads is neutralised by treatment with barium hydroxide solution. Other means, such as heating, &c., may be employed for the removal of the acetone. The threads are not denitrated; and they may be redissolved when desired.—W. P. S.

Hydrosulphites [Hyposulphites]; Rendering aqueous solutions of —— stable. Soc. Anon. Plaques et Papiers Photographiques A. Lumière et ses Fils. Fr. Pat. 360,980, March 21, 1905. VII., page 537.

Discharging on coloured grounds; Method of ——. Badische Anilin und Soda Fabrik. First Addition, dated Oct. 21, 1905, to Fr. Pat. 355,117, June 9, 1905.

See Eng. Pat. 15,524 of 1905; this J., 1906, 474.—T. F. B.

English Patents.

Dyeing hairs; Means for and process of ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 14,212, July 10, 1905.

Hairs are dyed fast shades by treatment with an alkaline solution of a sulphonic acid of *p*-phenylenediamine, *p*-toluylenediamine, *o*- or *p*-aminophenol, *p*-aminodiphenylamine, &c., with or without an oxidising agent. Fast reddish-brown shades may be produced by dyeing the hair with a solution of 4 parts of *p*-aminodiphenylaminesulphonic acid, 2 parts of calcined sodium carbonate, and 4 parts of a 25 per cent. solution of sodium hydrogen sulphite in 100 parts of water, to which is added 50 parts of 3 per cent. hydrogen peroxide solution.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 478.)

Nitrogen; Oxides of ——, *and the chamber process* [*sulphuric acid*]. G. Lunge and E. Berl, Z. angew. Chem., 1906, **19**, 807–819, 857—869, and 881—894.

The authors summarise their results as follows:—

1. Liquid nitrogen peroxide, as well as the gaseous mixtures of NO_2 and N_2O_4 which it furnishes, gives accurate analytical results, when absorbed by concentrated sulphuric acid in an appropriate apparatus, even when diluted with considerable volumes of oxygen, nitrogen, or air, the ratio of nitrogen to oxygen being exactly that required on the hypothesis of the formation from the peroxide of equimolecular quantities of a nitroso-derivative ($ONO.SO_3H$) and a nitro-derivative ($NO_2.OH$). (See Raschig, this J., 1905, 923.) 2. Sodium hydroxide also gives accurate results when it absorbs nitrogen peroxide, whether as liquid or gas, alone or diluted with an inert gas such as nitrogen, both as to the amount absorbed and the proportions of nitrate and nitrite formed. If, however, the gaseous peroxide be diluted with oxygen or air, some of the nitrite is, at the moment of formation, oxidised to nitrate; such mixtures therefore cannot be analysed by absorption in sodium hydroxide. The sensitiveness of sodium nitrite to oxidation at the moment of its production probably has an important bearing on the question of the production of nitric acid or nitrates from nitrous gases. 3. Gaseous mixtures of nitric oxide and nitric oxide are also absorbed completely by sulphuric acid, provided the molecular ratio of the former to the latter is not greater than unity; no doubt, the peroxide is first converted into nitrosylsulphuric acid and nitric acid, but the latter as formed, is instantaneously reduced by the nitric oxide to nitrosylsulphuric acid, so that an equimolecular mixture of nitric oxide and nitrogen peroxide behaves as though it were nitrogen trioxide. Any excess of nitric oxide beyond this proportion will escape unabsorbed. 4. The mixtures considered in 3 are not quantitatively absorbed by dilute solutions of sodium hydroxide; the peroxide gives nitrate and nitrite, but the nitric oxide cannot reduce the nitrate to nitrite sufficiently quickly and so escapes; thus there is a loss of nitrogen compound, and too high a ratio of nitrate to nitrite. In this respect (and no doubt in others), an equimolecular mixture of nitric oxide and nitrogen peroxide ($NO+NO_2$) is not equivalent to nitrogen trioxide (N_2O_3). 5. Not only is there no loss during the absorption of nitrogen peroxide by sulphuric acid, but the speed of absorption, even in 80 per cent. acid, is very great. Raschig's speculations based on the contrary propositions thus fall to the ground. 6. Rubber corks and connections must not be used where they will come into contact with nitrous gases. 7. When nitric oxide and excess of air are shaken with much water nitric acid is formed, no doubt through atmospheric oxidation of the first-formed nitrous acid. 8. Gaseous nitric oxide, mixed with excess of air, is oxidised directly to peroxide, *i.e.*, without passing through the intermediate stage of trioxide at all. The authors cannot discover, either in Raschig's observations or their own, the angle in the reaction-curve which, according to him, shows the completion of the rapid conversion into nitrogen trioxide and the beginning of the slow formation of nitrogen peroxide. 9. This argument for the existence of nitrogen trioxide having failed, and there being no other chemical argument in favour of its existence, and no physical one for temperatures above 50° C., there can be no justification for assuming the existence of nitrogen trioxide in any theory of the chamber process. 10. Chamber crystals are not nitrosulphonic acid, but nitrosylsulphuric acid; the nitrosyl formula must also be used for their solution in sulphuric acid. 11. Raschig's theory of the chamber process cannot be maintained: it ignores the existence of nitrosylsulphuric acid; it demands as intermediary an imaginary substance, nitrososulphonic acid, the assumption of which in no way simplifies our conceptions; it would involve the formation in the chamber of nitrous oxide, hydroxylamine and ammonia, none of which occurs; and it postulates the continual formation and reaction of nitrous acid, which also is not present. 13. Nitrosylsulphuric acid acts as carrier of oxygen. 14. Trautz' blue compound, SO_5NH_2 (called by Raschig nitrosisulphonic acid) is formed, though momentarily, in the reaction of nitrogen peroxide or nitrous acid on sulphurous acid, and in the reduction of nitrosylsulphuric acid. It is readily converted into nitrosylsulphuric acid, either by free oxygen or by nitrogen peroxide. The nitrosylsulphuric acid is then either hydrolysed into sulphuric acid and nitrous acid (which instantaneously resolves itself into nitric oxide, nitrogen peroxide, and water), or reacts, as in the Glover tower, with sulphurous acid, forming sulphuric and nitrosisulphonic acids. 15. The following are the reactions occurring in the chamber:—

1. $SO_2+NO_2+H_2O=O:N(OH)SO_3H$
2*a*. $2[ON(OH)SO_3H]+O=H_2O+2(O_2N.SO_3H)$.
$\downarrow$
$2(ONO.SO_3H)$
2*b*. $2[ON(OH)SO_3H]+NO_2=NO+H_2O+2(ONO.SO_3H)$
3*a*. $2(ONO.SO_3H)+H_2O=2SO_2(OH)_2+NO+NO_2$
3*b*. $2(ONO.SO_3H)+SO_2+2H_2O=H_2SO_4+2[ON(OH)SO_3H]$.
3*c*. $ON(OH)SO_3H=NO+H_2SO_4$
4. $2NO+O_2=N_2O_4$.

—J. T. D.

Nitric oxide; Formation of —— *at high temperatures.* W. Nernst. Z. anorg. Chem., 1906, **49**, 213—228.

The formation of nitric oxide from the air by the agency of electric sparks or the arc is known to be purely a heat phenomenon, and the author has experimentally investigated the reaction, $N_2+O_2=2NO$, at high temperatures, ascertaining the equilibrium concentration of the nitric oxide. Air was passed at known rates and in known quantities through electrically heated tubes of platinum or iridium, the temperature of which was measured by the thermo-electric junction or photometrically. It then passed on through concentrated sulphuric acid, from which the nitric oxide was afterwards liberated by mercury, and measured. The results obtained agreed well with those calculated. Equilibrium was found to be more rapidly established as the temperature increased. The following table illustrates how the equilibrium concentration (x) of nitric oxide, in volume per cent., varies with the temperature:—

Temp. °C.	x.
1227	0·10
1627	0·46
2027	1·23
2427	2·44
2827	4·39

When oxyhydrogen gas is exploded with air it has been shown by Bunsen and by Finckh (this J., 1905, 693) that nitric oxide is formed and that the amount varies with the pressure, *i.e.*, the time of reaction. The reason for this is now made clear, and by referring to the above table, the maximum amount of nitric oxide obtainable at the explosion temperature, about 2400° C., may be found.

—F. Sodn.

Nitric oxide; Decomposition velocity of ——. K. Jellinek. Z. anorg. Chem., 1906, **49**, 229—276. (Compare previous abstract.)

The reversible reaction $2NO \rightleftarrows N_2+O_2$ is found by the author to be bimolecular in either direction, between the temperatures 650° and 1750° C. Nitric oxide decomposes at a measurable rate even at 670°, the dependence of the decomposition constant k on temperature being expressed at high temperatures by the equation $\log k=AT+B$. The time required for the completion of half the decomposition of the gas at atmospheric pressure is calculated as $7{\cdot}35\times10^{3}$ minutes at 900° (absolute), and as $2{\cdot}25\times10^{-9}$ minutes at 3100° abs., about a billion times less. And,

starting with air, a still more marked variation is observed in the times necessary for the formation of one-half the possible quantity of nitric oxide. When oxyhydrogen gas is exploded with air, the actual heating time has been calculated from the above equation, assuming the temperature, and is of the order 10^{-4} seconds. In the decomposition of nitric oxide platinum proves to have a catalytic action, decreasing with rise of temperature, and iridium also acts as a catalyst.—F. Soddy.

Chromic acid; Constitution of ——. W. Manchot. Ber., 1906, **39**, 1352—1356.

When chromic acid oxidises ferrous, titanous, or uranyl salts in presence of potassium iodide, three equivalents of oxygen are liberated for each atom of iron (&c.), of which one goes to the iron (two to the uranium), while the rest liberate iodine. Chromic acid and anhydride, therefore, must have the constitutions,

$$(OH)_2Cr<^{O}_{O} \text{ and } O:Cr<^{O}_{O},$$

respectively. This accords with the old observation of Weltzien, confirmed by the author, that on heating potassium bichromate with sulphuric acid, ozone is evolved. Probably the first stage, in oxidations by chromic acid, is the attachment of the chromic acid molecule to the oxidisable substance.—J. T. D.

Barium carbonate; Dissociation of ——. A. Finkelstein. Ber., 1906, **39**, 1585—1592.

By passing air over barium carbonate heated in an electric furnace, and measuring the percentage of carbon dioxide in the issuing air, the relation between temperature and dissociation-pressure was studied.

The first step is the formation of a basic carbonate, probably $BaO,BaCO_3$, which melts at a lower temperature than the normal carbonate, and which, by coating the yet undecomposed carbonate, somewhat interferes with the progress of the reaction. The fused basic carbonate seems to dissolve both the oxide and the normal carbonate. Complete dissociation of the basic carbonate at the atmospheric pressure occurs about 1450° C. The basic carbonate is formed from its constituents with absorption of heat. The specific heat of barium carbonate appears to vary with the temperature in the same fashion as that of carbon dioxide. Incidentally, it was found that barium carbonate obstinately retains traces of moisture, which can only be completely removed by heating to 1000° C. in a stream of dry carbon dioxide.—J. T. D.

Sodium sulphates; Acid ——. J. D'Ans. Ber., 1906, **39**, 1534—1535.

If a solution containing sodium sulphate and sulphuric acid in equimolecular proportions be evaporated, needle-like crystals separate, which, after washing first with dilute sulphuric acid and alcohol, then with alcohol and ether, have the composition expressed by $Na_3H(SO_4)_2$.

To obtain the hydrate, $Na_3H(SO_4)_2.H_2O$, a solution containing 16·5 per cent. of sulphuric acid and 35 per cent. of sodium sulphate is heated to 30° C., and the two substances, in the proportions in which they exist in $Na_3H(SO_4)_2$ are gradually added, till, on cooling (and if necessary seeding with a crystal), the salt separates. It forms brilliant rhombic prisms.—J. T. D.

Fischer's salt [Potassium cobaltinitrite] and its decomposition by heat. P. C. Ray. Chem. Soc. Trans., 1906, **89**, 551—556.

Preparation.—On adding different quantities of a strong solution of potassium nitrite, acidified with acetic acid, to a fairly concentrated solution of cobalt chloride, the salt, $Co_2(NO_2)_6.6KNO_2.3H_2O$, is generally formed, but it invariably carries down with it traces of an oxide of cobalt, the figures for this metal being always too high, and those for potassium too low. In one or two cases results were obtained which appear to support Sadtler's statement (Amer. J. Science, 1870 [ii], **49**, 192) that the degree of hydration of the product depends upon the concentration of the solutions employed. Rosenheim and Koppel (Z. anorg. Chem., 1898, **17**, 35) state that by passing a current of nitrogen trioxide into a solution of potassium nitrite holding cobalt carbonate in suspension, a pure anhydrous salt is obtained. The author finds, however, by this method also, a trihydrated salt is obtained, and that it is contaminated with appreciable quantities of an oxide of cobalt.

Decomposition.—The author is unable to confirm Erdmann's statement (J. prakt. Chem., 1866, *7*, 401) that potassium cobaltinitrite evolves nitrous acid on heating. When heated without access of air, the salt begins to give off nitric oxide below 200° C., whilst at 210°—215° C., decomposition proceeds smoothly according to the equation:

$$Co_2(NO_2)_6.6KNO_2.3H_2O = Co_2O_3 + 6NO + 3KNO_3 + 3KNO_2 + 3H_2O.$$

If the salt be heated in an air-bath, the potassium nitrite is converted into nitrate, the nitric oxide acting as an oxygen-carrier.

Analysis.—A weighed quantity of the salt is heated in an air-bath for two hours at 215°—220° C., and the residue repeatedly washed by decantation with boiling water and collected on a filter. The cobalt is then determined by Rose's method, the analysis being carried out without the use of reagents. The potassium in the solution is determined as sulphate.—A. S.

Cupric oxide; Colloidal ——. C. Paal and W. Leuze. Ber., 1906, **39**, 1545—1549.

By the same process as for the corresponding silver and mercuric compounds (this J., 1902, 994) the authors have prepared blue-violet solutions of colloidal cupric hydroxide. On dialysis, traces of copper compound always pass through, for reasons not yet discovered. The solution in the dialyser gradually changes colour to dark brown, possibly through dehydration. The colloidal solution is extremely stable and yields on evaporation to dryness, a solid residue which after an indefinite lapse of time is still soluble in water, regenerating the original solution.—J. T. D.

Uranium ores; Treatment of Vanadiferous — —. M. Gin. Sixth Internat. Congr. of Appl. Chem., Rome. Z. angew. Chem., 1906, **19**, 896.

The ore is fused with potassium bisulphate, the acid vanadic sulphate converted into divanadyl sulphate, and the solution treated with a mixture of ammonia and ammonium carbonate, which forms an insoluble hypovanadate and a soluble ammonium uranium carbonate.

A second method depends on the property of ferric chloride of reacting on vanadic anhydride to form vanadium trichloride, which boils at 126° C., and can be distilled off and received in water, forming pure vanadic acid.—J. T. D.

Uranyl acetate; Action of light on ——. A. Bach. Ber., 1906, **39**, 1672—1673.

The author had shown formerly that on passing carbon dioxide through a solution of uranyl acetate, exposed to direct sunlight, reduction of the salt to a mixture of uranous and uranic hydroxides takes place. Euler showed subsequently that carbon dioxide is merely active in removing from the solution oxygen which hindered the reaction and that the reduction takes place also in sunlight alone. The author now finds that in his former experiments a chance equilibrium had existed between the reducing action of the light and the oxidising influence of the oxygen, thus confirming Euler's view. He shows that with constant illumination, uranyl acetate concentration, and diameter of the tube employed, the time required until a perceptible cloud is formed (marking the beginning of the reaction) is inversely proportional to the height of the liquid column. When the relation between the liquid surface exposed to the air and the height of the liquid has reached a certain value, reaction no longer takes place. If the illumination, diameter, and height of the liquid column are kept constant, the rate of change is inversely proportional to the concentration of the uranyl acetate. Hot saturated solutions become clouded almost at once when exposed to light. Preparations obtained by the fractional

eduction of uranyl acetate solutions in sunlight, re-oxidation of the washed precipitates exposed to the air and dissolution of these in acetic acid, show a similar behaviour owards light, and there are no grounds for assuming the resence of a photo-catalysator in uranyl acetate.
—E. F. A.

Nitrogen; Properties of liquid ——. H. Erdmann. Ber., 1906, **39**, 1207—1211.

By passing nitrogen from a cylinder through a cooling orm into a cylindrical copper vessel cooled by liquid air, he gas can be liquefied in large quantities at any pressure etween 0·7 and 2·5 atmospheres, and then, after filtration hrough an ordinary paper, forms a perfectly colourless obile liquid. Not only ice, but absolute alcohol, sinks n this liquid, so that Ramsay and Drugman's figure for ts density (0·7914) is probably nearer the truth than Dewar's (0·850). Liquid nitrogen forms an excellent ooling agent, its lower temperature rendering it more fficient than liquid air. It is a good solvent for liquids f low boiling point; is miscible in all proportions with iquid oxygen or liquid ozone; and seems well adapted s a solvent for determining the molecular weights of such ubstances. Liquid nitrogen is inert towards most ubstances, and even metals like calcium and magnesium lo not readily combine with it; but a mixture of calcium rillings and liquid nitrogen, if ignited by "thermite" gnition-mixture, continues to burn, and forms calcium itride. The author is investigating the molecular eight of liquid nitrogen, to ascertain the suitability of he gas as a material for standard thermometers.
—J. T. D.

Phosphorus; Constituent producing electrical conductivity in air which has passed over ——. R. Schenck, F. Mihr and H. Bauthien. Ber., 1906, **39**, 1506—1521.

The authors find that the phenomenon of ionisation of he air in the vicinity of white phosphorus is not directly onnected with the luminescence of the phosphorus, for nany other substances showing similar luminescence roduce no effect in discharging a charged electroscope. t is not due to ozone, but to phosphorus trioxide, for reviously prepared pure phosphorus trioxide, mixed in ninute proportion with air, produces the same effect as ir which has passed over white phosphorus. The authors ave determined the vapour pressure of the trioxide t temperatures from 22° to 91° C., the rate of its oxidation, ts molecular weight at 80° C. (at which temperature they ound the figure 218, so that no molecular dissociation had occurred), the electric conductivity (it is a good insulator), nd the dielectric constant. From none of the results ave they been able to get a clue to the cause of the onising action of the trioxide upon air.—J. T. D.

Phosphorus; Method of detecting minute quantities of white ——. R. Schenck and E. Scharff. Ber., 1906, **39**, 1522—1528. (See preceding abstract.)

The discharge of an electroscope by air which has remained n the vicinity of white phosphorus forms an exceedingly elicate test for the latter, and the authors have devised convenient and compact form of electroscope for the pplication of the test. The substance to be tested is laced in a U-tube connected with the cylindrical vessel urrounding the electroscope rod, and, after a short time, he air in the apparatus is blown by a small hand-bellows hrough into the cylinder. So small a quantity of phosphorus in the U-tube as 0·004 mgrm. increases quite ensibly the rate of discharge. The method will be of use for detecting small quantities of white phosphorus in phosphorus sulphide or red phosphorus, as also for detecting vapours of phosphorus trioxide in the air of rooms in match factories, &c.—J. T. D.

Phosphorus sulphides; Existence of ——. R. Boulouch. Comptes rend., 1906, **142**, 1045—1047.

The author doubts the existence of Giran's eutectic of the composition, P_4S (this J., 1906, 264), finding that the only eutectic point of mixtures containing more phosphorus than the sulphide, P_4S_3, occurs at —7° C., and has the composition corresponding to P_4S. These mixtures possess in a high degree the power of remaining as supercooled liquids, and unless they are seeded with the sesquisulphide, P_4S_3, they may be cooled far below their real freezing-point without solidifying. Moreover, the freezing-point curve of mixtures of the sesquisulphide (43·6 per cent. of sulphur) and phosphorus presents a sudden inflexion at 36 per cent. of sulphur (which mixture freezes exactly at the freezing-point of phosphorus), and declines much less steeply as the percentage of sulphur decreases further; and the eutectic point is at the intersection of this line with the line falling from pure phosphorus as sulphur increases, at —7°C., not at the intersection of the latter with the continuation of the first part of the line falling from the sesquisulphide as sulphur decreases, which would be about —40° C.—J. T. D.

Arsenical sulphur ores; Treatment of —— *for the obtainment of arsenious acid and of sulphuric acid deprived of arsenic.* J. Raschen, A. E. Wareing, and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 16,931, Aug. 21, 1905.

The gaseous products from the burning of arsenical sulphur ores are passed into a Glover tower, down which sulphuric acid flows. The sulphuric acid, thus charged with arsenious oxide, is subjected, at a temperature of about 100° C., to the action of dry hydrochloric acid gas, preferably in a suitably packed tower. The arsenious chloride formed is withdrawn, as an oily liquid, from the sulphuric acid thus treated, and is brought into contact with an alkali, alkali carbonate, earth carbonate, or the like, in the presence of a small proportion of water, to precipitate arsenious acid, which, if necessary, may be purified by sublimation. (See also Eng. Pats. 16,929, 16,930, and 17,887 of 1905, this J., 1906, 477; and 17,886 of 1905, following abstract.)—E. S.

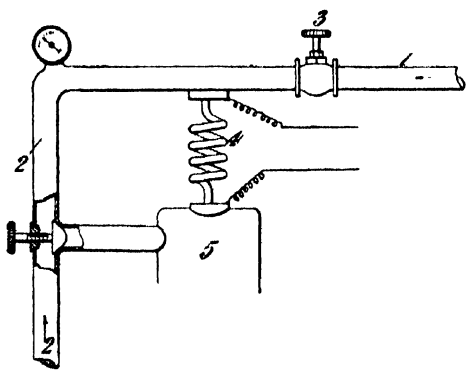
Sulphuric acid; Treatment of gases obtained from arsenical ——, *and other gases containing arsenious chloride, and the obtainment of arsenious acid therefrom.* J. Raschen, A. E. Wareing, and The United Alkali Co., Ltd., Liverpool. Eng. Pat. 17,886, Sept. 4, 1905.

The gases evolved on the treatment of arsenical sulphuric acid with hydrochloric acid, and blowing air through (as described in Eng. Pat. 7916, of 1905; this J., 1906, 477), are passed into a minimum quantity of water containing an alkali, or alkaline earth, or carbonate thereof; or certain oxides or carbonates of the heavy metals, such as zinc oxide or carbonate, manganese-mud, or iron hydroxide. The arsenic in the gases is stated to be precipitated "in the form of arsenious acid." The process may be applied generally to the treatment of gases containing arsenious chloride. (Compare Eng. Pats. 16,929, 16,930 and 17,887 of 1905, this J., 1906, 477.)—E. S.

Ammonia; Production of —— *[from the air].* H. C. Woltereck, London. Eng. Pat. 8358, April 19, 1905.

Carbonaceous material (other than peat) is heated, preferably in upright retorts, to a temperature not exceeding 500° C., and air and steam are passed through the mass, the production of combustible gases being, as far as is possible, prevented. The heating may, at the commencement, be effected by the incipient combustion of the lower portion of the charge, and afterwards, in some cases, water in the form of spray may be introduced for the production of the steam required. It is stated that the ammonia formed, owes its origin, partly or wholly, to the nitrogen of the air admitted. The effluent gases are scrubbed, passed through an "alkali tower, or its equivalent, to liberate all ammonia," and then through sulphuric acid absorption towers. (Compare Fr. Pat. 345,399 of 1904; this J., 1904, 1215.)—E. S.

Corrosive liquids; Apparatus for spreading or distributing —— specially applicable to the manufacture of copper sulphate and the like. H. E. Dolphin, Chester. Eng. Pat. 9239, May 2, 1905.



A TOWER, charged with, for instance, copper shot to be dissolved, having near its bottom an outlet pipe for flow of the solution into a receptacle, and receiving a jet of air or steam, is sprayed at the top with dilute sulphuric acid, delivered from a siphon into a shallow cup or saucer, over the edge of which the liquid splashes in an umbrella-shaped shower, with such force as to be further sprayed, on contact with the shot, over the entire surface. The saucer may be replaced by a disc or plate, or by an inclined surface attached to one side of the inside of the tower, from which the gushes of liquor from the siphon may be splashed over the charge.—E. S.

Sulphur dioxide and Glauber salts; Manufacture of pure ——. W. Garroway, Glasgow. Eng. Pat. 11,986, June 8, 1905.

SODIUM bisulphite solution, formed by acting upon sodium carbonate with sulphurous acid, and solution of nitre cake (sodium bisulphate) are separately admitted to a closed mixing vessel, supplied with a steam heating coil, from which vessel the sulphur dioxide set free is conducted through a tower and a pair of small vessels into a large vessel in which the gas is absorbed by water. (Reference is directed to Eng. Pats 2784 of 1880 and 1393 of 1888.)—E. S.

Catalytic apparatus. [*Manufacture of nitric oxide from ammonia.*] H. H. Lake, London. From Nordyke and Marmon Co., Indianapolis, U.S.A. Eng. Pat. 1204, Jan. 16, 1906

IN the figure shown, 4, is a helical coil, of small diameter relatively to its length, of a metal of the platinum group,

which is heated, at first to a temperature slightly below visible redness. Ammonia gas is admitted through the tube, 1, controlled by the cock, 3, and air enters by the tube, 2, the mixture passing through the helix and entering the receiver, 5, for the nitric oxide formed. The reaction is stated to be endothermic or exothermic, according to whether the air or the ammonia is admitted in excess, so that the temperature may be regulated without external heating after passing the initial stage of the process. The process may be conducted under pressure. The apparatus is generally applicable in catalytic processes. —E. S.

Cyanogen compounds; Process for the recovery of —— from crude gases and from bye-products in the manufacture of cyanides. W. E. Sims and H. Bowes, Manchester. Eng. Pat. 2929, Feb. 7, 1906.

IN the manufacture of cyanides from a ferrocyanide solution and sulphuric acid, the hydrocyanic acid distilled off is collected and neutralised in the usual way, and the insoluble compounds remaining in the still are removed, freed from excess of acid and soluble salts, and then mixed with caustic alkali or alkali carbonate. The alkaline mixture, with or without addition of ferrous hydroxide or carbonate, is subjected to the action of sulphuretted gases containing cyanogen compounds. By this treatment the insoluble cyanogen compounds are converted into ferrocyanide, the completion of the reaction being indicated by the disappearance of the fixed alkalinity of the mixture, which now contains ammonia compounds with ferrocyanides and ferrous sulphide. The ammonia is recovered from the product in a suitable still, and the solution of alkali ferrocyanides, after separation of insoluble matters, is purified when necessary, and distilled with sulphuric acid, as first described, to obtain hydrocyanic acid. The insoluble residues from the filtration residue, together with the insoluble distillation residue, are again used in the described cycle of operations.—E. S.

FRENCH PATENTS.

Endothermic compounds [*e.g., oxygen compounds of nitrogen*]; *Process and apparatus for producing ——.* R. Pawlikowski. Fr. Pat. 361,119, Dec. 26, 1905.

THE invention is described with reference to effecting the combustion of nitrogen in the oxygen of the air, and to compensate for the absorption of heat that ensues, the temperature is raised in the operating cylinder by the sudden compression of the contained air, by the movement of a piston, *k*. The compression takes place at intervals, the movements of the piston inducing, in succession, aspiration through the valve, *e*, of air already heated by passage through the heat exchanger, W. When the piston arrives at or near its highest point, either a combustible is introduced through the valve, *f*, and is ignited to increase the heat, or electric sparks are passed through. As the piston makes its downward movement, work is done by the expansion of the compressed air, and on the return, the gases are forced through the valve, *a*, through the heat exchanger, whence the air carrying the nitric oxide formed, is passed to an absorber. The inner surfaces of the cylinder, not coming into contact with the piston, may be lined with a carborundum mixture, or with spongy platinum, &c., intended to act catalytically in aid of the reaction.—E. S.

Hydrosulphites [*Hyposulphites*]; *Rendering aqueous solutions of —— stable.* Soc. Anon. Plaques et Papiers Photographiques A. Lumière et ses Fils. Fr. Pat. 360,980, March 21, 1905.

AQUEOUS solutions of alkali hydrosulphites, say, of 3 per cent. strength, are rendered, comparatively, stable in air, by addition of certain proportions of tribasic sodium phosphate, acetaldehyde, trioxymethylene in presence of sodium sulphite, benzaldehyde, or hexamethylenetetramine. The presence of sodium phosphate does not interfere with the reducing properties of the hydrosulphite at ordinary temperatures; but the other substances named allow reduction to take place only near 100° C. Or, the anhydrous sodium hydrosulphite of the Badische Anilin und Soda Fabrik may be mixed with tribasic sodium phosphate, or with trioxymethylene and sodium sulphite, to form a powder, which, when dissolved in water, gives a stable solution. (Reference is made to Fr. Pat. 338,385, of 1903.)—E. S.

Sulphite liquors; Preparation of strong —— and apparatus therefor. G. Türk. Fr. Pat. 361,071, Dec. 9, 1905.

SULPHUR dioxide gas is delivered under pressure, near to the bottom of the lower, and larger, compartment of a tank, containing a dilute solution of sodium carbonate, or water in which milk of lime is diffused, through a series of nozzles so curved as to cause the gas to issue with rotary motion, in the form of very minute bubbles. The excess of the gas passes from the upper portion of the compartment, by a tube leading outside the tank, and curved downwards into the upper compartment, on the floor of which it forms a horizontal perforated extension, through which the gas issues into water, or into a solution corresponding to that in the lower compartment of the tank. An aperture, ordinarily kept plugged, is provided in the floor of the upper compartment, through which, when desired, the liquor contained therein may be discharged into the lower compartment.
—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 478.)

Silicate-melts and silicate-glasses. C. Doelter. 6th Int. Cong. appl. Chem. Z. angew. Chem., 1906, **29**, 805—807.

SILICATES may be divided into two groups entirely different from each other, but which may be connected by a series of intermediate bodies. The first group comprises silicates with a sharply defined melting-point, small viscosity, high power of crystallising, and great rapidity of crystallisation; they are but little dissociated, and do not show supersaturation or supercooling. To this group belong the calcium- and magnesium—iron—manganese silicates, as well as those of the formulæ, $CaMgSi_2O_6$, $CaFeSi_2O_6$, $Na_2CaSi_2O_6$. They do not form glasses. To the second group belong those silicates which yield glasses. They possess properties opposite to those of the first group, the most marked being the indefinite melting point, a viscous state corresponding to an interval of temperature of 100° C. and more separating the liquid from the solid state; the solidifying point is always below the melting point; and practically no heat is absorbed during solidification. To this group belong most of the sodium, potassium and aluminium silicates. The silicates of the first group are sharply differentiated from alloys, by the fact that in those circumstances where the latter would form eutectic mixtures so closely mixed as to seem definite chemical compounds, the former show exactly the opposite tendency, different silicates separating out as far apart as possible. The members of the second group do not show this peculiarity, which may be seen in many rocks.
—A. G. L.

Emery; Naxos ——. For. Off. Ann. Ser., No. 3592.

THE export of Naxos emery stone from the Government depot at Syra was again very satisfactory last year, amounting to a total of 6395 metric tons, valued at 27,170*l.*, being 42 tons in excess of the export in 1904. It was shipped as follows:—3350 tons to Rotterdam, 1010 tons to Liverpool, 1000 tons to New York, 630 tons to Havre and 405 tons to Boston. Of the total, German steamers carried 2850 tons, British 2415 tons, French 630 tons and Austro-Hungarian 500 tons. [T.R.]

UNITED STATES PATENTS.

Glass; Apparatus for the manufacture of sheets of ——. F. L. O. Wadsworth, Morgantown, W. Va., Assignor to Pressed Prism Plate Glass Co., New York. U.S. Pat. 818,209, April 17, 1906.

THE apparatus consists of a combination of a rolling mechanism and a frame which receives the glass as it passes from the rolling mechanism and by which the sheet is held vertically, means whereby a wire mesh may be supported in the frame in position to be embedded in the glass sheets, and vertical pressure-plates adapted to press the glass.—A. G. L.

Glass sheets; Apparatus for the manufacture of ——. F. L. O. Wadsworth, Morgantown, W. Va., Assignor to Pressed Prism Plate Glass Co., New York. U.S. Pat. 818,210, April 17, 1906.

THE apparatus consists of a sheet-forming roll, a table, a series of figured dies elevated above the path of the roll, and mechanism by which the dies are moved successively against the sheet as the roll passes.—A. G. L.

(*Continued from page* 479.)

ENGLISH PATENT.

Marble and stone; Manufacture of artificial ——. T. M. Thorn, Cheshunt, Herts. Eng. Pat. 8804, April 26, 1905.

THIS invention relates to the production of artificial marble or stone, by submitting blocks or slabs of lime to the action of carbon dioxide in a closed vessel, in a special way. The vessel containing the slabs to be carbonated is exhausted by a pump, and carbon dioxide is then admitted, until the vacuum is largely reduced. As the gas is absorbed by the slabs and the pressure in the vessel consequently decreases, a further quantity of gas is admitted until the pressure rises again to its original amount, and the process is continued until the pressure remains constant, that is, until the slabs cease to absorb further quantities of gas.—W. C. H.

UNITED STATES PATENTS.

Clays containing gypsum; Treating ——. K. Sakurai, San Francisco, Cal. U.S. Pat. 818,124, April 17, 1906.

THE clay is heated to a temperature of about 200° C., so as to dehydrate the gypsum and render it "dead-burnt," without changing the clay, and is then mixed with a suitable binder, moulded whilst pasty, and dried.
—A. G. L.

Clay; Process of treating ——. E. S. Powers, Merchantville, N.J. U.S. Pat. 818,287, April 17, 1906.

CLAY and sand are mixed with a "liquid solution of silica," or similar inorganic substance; the mixture is moulded, exposed to the atmosphere and then heated, whereby a crust of crystallised silica is formed on the surface, which prevents shrinkage of the material.—A. G. L.

Bricks; Composition for the construction of ——. E. R. Stowell, Portland, Ind. U.S. Pat. 819,467, May 1, 1906.

THE composition is composed of amorphous carborundum and Portland cement.—A. G. L.

Cement-kilns ; Process of operating ——. H. L. Doherty, Madison, Wis. U.S. Pat. 818,018, April 17, 1906.

FROM 5 to 25 per cent. of the finished cement clinker is mixed with the raw materials, and again passed through the rotatory kiln.—A. G. L.

Combustion [in cement kilns] ; Process of conducting ——. H. L. Doherty, Assignor to Combustion Utilities Co., New York. U.S. Pat. 819,127, May 1, 1906.

A FLAME of producer gas opposite in direction to that of the cement raw material is produced in a rotatory kiln, and powdered coal and air is projected into this flame at a point close to the clinkering zone so as to give an intense local heating effect.—A. G. L.

X.—METALLURGY.

(*Continued from page* 482.)

Cast iron ; Volume and temperature changes during cooling of ——. T. Turner. Iron and Steel Inst., May, 1906.

A T-SHAPED bar was cast, the head of which was kept rigidly fixed by the sand of the mould and by a steel pin clamped to the iron box containing the mould. In the other end was inserted a wire nail, round the head of which the bar solidified, and the point of which was connected with a lever multiplying index, in order to record alterations in the length of the bar. A thermo-electric pyrometer, inserted at the middle of the bar, allowed of temperature-readings being made. From the shrinkage readings and the time and also from temperature-readings and time, curves were constructed. These curves group themselves into four classes :—1. Those showing no arrest in the shrinkage, illustrated by copper, aluminium, antimony, lead, tin, zinc, and zinc-aluminium alloys. 2. Those showing one retardation of shrinkage, which may amount to actual expansion ; illustrated by white iron and by high carbon steel, also by zinc-copper alloys. 3. Those showing two such arrests, illustrated by non-phosphoric grey iron ; and 4. Those showing three such arrests, illustrated by very grey phosphoric irons. In this class, the third arrest is by far the most considerable, while the second is small relatively to either of the other two.

The cooling curves show arrests, which may amount even to rises of temperature, corresponding to the arrests or expansions in the shrinkage curves.

The examination of four characteristic irons—1. Pure white cast iron ("American washed iron"), 2. non-phosphoric grey iron (No. 3 hæmatite pig), 3. Phosphoric grey iron (No. 1 Northampton), 4. Close-grained foundry iron, from a broken-up casting, gave results as follows :—

	1.	2.	3.	4.
Carbon, combined ...	2·73	0·86	0·15	0·79
graphitic ...	—	2·53	2·60	2·73
Silicon	0·01	3·47	3·98	1·41
Sulphur	tr.	0·03	0·03	0·07
Phosphorus	0·01	0·04	1·25	0·96
Manganese	tr.	0·55	0·50	0·43
First arrest.....	almost absent	1135° C.	1060° C.	1095° C.
Second „	absent	absent	900° C.	905° C.
Third „	665° C.	695° C.	730° C.	695° C.

The third expansion becomes more marked, and occurs at a higher temperature, as the silicon increases. The author considers it probable that the cause of this expansion is the separation of temper-carbon. He recommends tests on the lines of the experiments in the paper as a means of checking and controlling mixtures in the foundry. —J. T. D.

Cast iron ; Influence of the condition of the carbon on the strength of ——, *as cast, and heat-treated.* W. H. Hatfield. Iron and Steel Inst., May, 1906. Reports of Carnegie Research Scholars. [Advance proof.]

THE highest tensile tests were given by low-silicon irons in which the combined carbon was at a maximum. Grey irons gave the lowest tensile results, through the weakening action of the graphite plates. Pearlite was found to strengthen the grey irons. Annealing weakens grey irons and strengthens white irons. The strength of the heat-treated white irons is largely influenced by the condition of the free carbon, and by the amount of combined carbon present as pearlite ; when the annealing carbon is finely divided the iron is strongest. Silicon appears to affect the strength of the iron only indirectly, through its action on the carbon ; and the temperature of casting seems also to be without direct influence.—J. T. D.

Iron and mild steel ; Deformation and fracture of ——. W. Rosenhain. Iron and Steel Inst., May, 1906. Reports of Carnegie Research Scholars. [Advance proof.]

THE author confirms his view that deformation occurs only by slip and twinning, and shows that the material between adjacent "slip-bands" undergoes no distortion. He explains Osmond's observations on the behaviour of slip-bands under powerful oblique illumination, by supposing that the surfaces exposed by slip are not perfectly smooth, but rough enough to scatter light. Experiments of Osmond and Frémont, and of Stead, on isolated crystals of iron have no bearing on metallic masses composed of crystalline aggregates, where the stresses are practically uniform over the small area of a single crystal. The partial plasticity following overstrain is probably due to formation of a layer of mobile molecules on surfaces of slip ; this layer is again absorbed into the crystalline system surrounding it, when recovery takes place. The mobile molecules only retain permanently an "amorphous" condition, as Beilby's theory requires, if deformation has been extremely severe. The author applies his method of obtaining transverse sections of surfaces by the aid of electro-deposits of copper to the study of fractures. He finds that in tensile fractures the break runs through ferrite and pearlite almost alike, because of the previous weakening of the pearlite by the gradual extension ; but in shock fractures, the ferrite is fissured and the pearlite as a rule unaffected. This detailed study of fractures gives a mode of locating causes of weakness and strength in a given microstructure, and may allow of tracing the causes of fractures occurring in actual work.—J. T. D.

Iron and steel ; Hardness of constituents of ——. H. C. Boynton. Iron and Steel Inst., May, 1906. Reports of Carnegie Research Scholars. [Advance proof.]

THE author has applied Jaggar's micro-sclerometer, in which the hardness of minerals is measured by the number of revolutions required for a tetrahedral diamond point rotating at constant speed and with constant pressure, to drill to a constant depth, to determine the hardness of the constituents of iron and steel. The summarised results are as follows :—

Constituent.	Present in	Relative hardness.
Ferrite.....	Electrolytic iron	1
„	„ „ (quenched)	2·15
„	Average of all unhardened samples	1·03
„	Commercial wrought irons	1·5— 3·6
Pearlite ...	Series of 0·13 to 1·52 per cent. carbon	1·8—10·3
„ ...	„ „ 0·35 to 0·86 „ „	3·8— 4·2
Sorbite	0·48 to 0·58 per cent. carbon steel	5·2—53·6
Troostite ..	Steel, 0·58 per cent. carbon	88·2
Martensite .	„ 0·20—1·52 per cent. carbon	38·9—261·6
Austenite ..	White cast-iron, 3·24 „ „	103·4
Cementite .	„ „ „ „ „	272·8

—J. T. D.

Manganese ; Preliminary note on the influence of —— *on iron.* J. O. Arnold and F. K. Knowles. Iron and Steel Inst., May, 1906. [Advance proof.]

THE authors have succeeded in preparing a series of nearly pure iron-manganese alloys. Swedish bar iron of 99·8 per cent. purity was melted in a special "one-cross" crucible made of the following mixture :—Unburnt Stourbridge fire-clay, 45 ; unburnt Derby clay, 21 ; unburnt Stannington fire-clay, 21 ; unburnt Cornish

china clay, 10; and coke dust low in sulphur, 3 per cent. The crucible mixture must be trodden for five instead of the usual three hours. The manganese, obtained by Goldschmidt's "thermite" process, was melted separately in a special crucible made of the following mixture:—Crystalline magnesia, fused in an electric furnace, 15 lb.; unburnt Stourbridge fire-clay, 12 oz.; and water containing 12½ per cent. by volume of "fluid silicate of soda," 650 c.c. The melting crucible was fitted closely into a protective ordinary plumbago crucible. After mixing the molten metals, half a minute was allowed for transfusion, and the alloys were then cast into 2-inch square ingots weighing about 35 lb. each. It is of importance that the two metals be made fluid at almost the same moment. The total period of melting is about 5½ hours, and the manganese should be charged into its crucible about 4½ hours after the iron. If the iron is melted before the manganese is ready, it begins to oxidise; such iron, containing about 0·2 per cent. of oxygen, is so red-short that it cannot be forged. It is proposed to investigate the chemical, thermal, microscopical, mechanical, electric and magnetic characteristics of the alloys in their normal, quenched and annealed conditions. In the preliminary work it has been observed that remarkable liquation takes place in the manganese-iron alloys. This is clearly shown by the following table:—

Ingot No.	Percentage of manganese in rolled bars.		
	One end.	Middle.	Other end.
977	3·07	3·48	3·42
944	10·60	13·85	11·96
906	26·53	28·24	35·14

—A. S.

Ferromanganese; Preparation of carbon-free ——. E. G. Ll. Roberts and E. A. Wraight. Iron and Steel Inst., May, 1906. Reports of Carnegie Research Scholars. [Advance proof.]

Of the methods proposed for eliminating carbon from ferromanganese—replacement by silicon or aluminium, cementation, reaction of oxide on the carbide Mn_3C—the authors find that the last is the only hopeful one. By fusing with manganese peroxide they have reduced the carbon in a ferromanganese from 6·72 to 2·79 per cent., and see no reason why on the large scale this should not be carried further. For success, however, the basic lining must be as low in silica as possible (not above 10 per cent.), the slag must be as high in manganous oxide as is consistent with fluidity, and the temperature should be above 1600° C.—J. T. D.

Steels; Quaternary ——. L. Guillet. Iron and Steel Inst., May, 1906. Reports of Carnegie Research Scholars. [Advance proof.]

The structures met with in normal hypo-eutectoid quaternary steels are: Pearlite and ferrite, pearlite and carbide, pearlite and graphite, ferrite and graphite, martensite, martensite and carbide, martensite and graphite, sorbite and carbide, γ-iron, γ-iron and carbide, γ-iron and graphite. More complex structures sometimes occur. The only simple structures are martensite and γ-iron. Martensitic structure corresponds with: very high tensile strength and elastic limit, medium or sometimes very low elongation, great hardness and great difficulty in working or forging. γ-Iron structure corresponds with: fairly-high tensile strength, low elastic limit, good elongation and resistance to shock in most cases, ease in forging, but difficulty in machining.

The characters of steels of complex structure are as follows:—1. All graphitic steels are unserviceable—brittle, impossible to roll or hammer. 2. Steels containing carbide have the characters of the other constituent, but accentuated; in particular the brittleness is increased. 3. Pearlitic steels have characters depending chiefly on the amounts of elements other than carbon present, and not on the quantity of pearlite alone; the tensile strength and elastic limit are seldom very high, but nothing can be predicted as to brittleness or elongation.

Quenching usually transforms pearlite into martensite, save in steels containing a fairly high percentage of aluminium. It leaves martensite unchanged, or tends to form from it γ-iron. It transforms sorbite into martensite, but does not transform γ-iron, save in certain steels on the boundary line of martensitic steels. The effect of quenching carbide steels varies with the nature of the carbide; chromium carbide steels need a temperature of 1200° C. for solution, tungsten or molybdenum carbide steels 850° C.; vanadium carbide steels are not altered by quenching.

Annealing as a rule does not alter structure. Pearlite becomes finer, martensite-needles better defined, γ-iron polyhedra and carbide grains larger. But γ-iron steels bordering on martensitic steels are transformed with formation of martensite.

Cooling and hammering do not usually affect structure, save in certain nickel steels bordering on martensitic steels. In any transformations, the effects are similar to those obtaining in the case of normal steels: A γ-iron steel becoming martensitic, for example, gains in tensile strength and elastic limit, and acquires lower elongation and resistance to shock.

There is but a limited field for the commercial employment of these steels. All steels having a structure which contains either martensite or graphite should be rejected—graphite, because of the brittleness it produces, martensite because of the difficulty of working or forging. Carbide steels containing γ-iron are of no interest; when pearlitic or sorbitic they may be of use for tool steels and for bearings. γ-Iron steels which are not too readily affected by such processes as quenching, annealing and cooling, can only be obtained by using high percentages of nickel, manganese, or both, and are thus costly; moreover their elastic limit is low, and they are difficult to work, so that they are of limited availability. There remain only the pearlitic steels, and these should not contain much carbide; the most promising of these are the nickel-vanadium and nickel-tungsten steels, and possibly the chromium-vanadium steels.—J. T. D.

Wire (steel); Heat treatment of ——, *particularly of wire for ropes.* J. T. Brunton. Iron and Steel Inst., May, 1906. Reports of Carnegie Research Scholars. [Advance proof.]

Steel wires, Swedish and British, were compared, raw and annealed, as to their mechanical properties and specific gravity, after successive drawings. Besides the maximum stress, tension, and elongation, the number of bendings over pulleys requisite to break the wire, under conditions similar to those demanded of a rope in actual work, was determined.

The most useful work was done by these wires when the specific gravity was increased by drawing to between 7·885 and 7·910; at these points the Swedish steel, with 0·75 per cent. of carbon showed a maximum stress of 90—99, and the British steel, with 0·83 per cent. of carbon, a maximum stress of 101—110 tons per square inch. By this method of testing, the best condition for work in the case of any given steel can be determined. The annealing of the rod before the final annealing does not in any way produce better material, and is unnecessary. By cold drawing, the specific gravity of the steel was increased from 7·768 to 7·998, but could not be further increased. Annealing reduced both the carbon and phosphorus in the wire; the phosphorus was not found in the scale, and hence must have gone off in some volatile form—the carbon no doubt is removed as carbon monoxide.—J.T.D.

Iron; The rusting of ——. G. T. Moody. Chem. Soc. Trans., 1906, **89**, 720—730.

Dunstan, Jowett and Goulding (this J. 1903, 745; 1905, 1235) have stated that the rusting of iron depends mainly on the direct interaction of iron, water and oxygen, and that the part played by carbonic acid in the process is merely subsidiary. The author shows that if effective precautions be taken to exclude carbonic acid, no interaction takes place between oxygen and iron in the presence

of water, but as soon as air containing its normal quantity of carbon dioxide comes in contact with the iron, vigorous rusting results. In one experiment a piece of iron in contact with water, and subjected to the action of a current of air freed from carbon dioxide, remained bright and unacted upon for five weeks.

To determine the influence of carbonic acid on the absorption of atmospheric oxygen by iron, 10 grms. of clean iron wire were left in contact, on the one hand, with ordinary air and distilled water which had been exposed to the air, and, on the other, with air which had been treated with soda-lime for 24 hours, and water distilled from barium hydroxide solution. The following results were obtained :—

	Percentage of total oxygen in 100 c.c. of air absorbed by 10 grms. of iron.	
	Ordinary air and distilled water.	Air and water almost entirely freed from carbonic acid.
After 6 hours' exposure	5·7	none
,, 24 ,, ,,	20·1	none
,, 72 ,, ,,	61·3	0·9
,, 168 ,, ,,	94·3	3·8

Analyses of samples of rust from the unpainted interiors of iron flushing tanks in constant use gave results at variance with Dunstan, Jowett and Goulding's view that the formation of hydrogen peroxide is a necessary part of the process of rusting (compare Divers, this J., 1905, 1235) a considerable proportion of the iron being present in the ferrous state. In six samples of rust, from 51·12 to 68·89 per cent. of the total iron was present as ferric oxide, from 23·18 to 36·57 per cent. as ferrous oxide, and from 7·93 to 12·31 per cent. as ferrous carbonate. The first stage in the atmospheric corrosion of iron is probably the formation of ferrous carbonate, which gradually becomes basic in character through loss of carbonic acid. As showing the ease with which iron is dissolved by carbonic acid, it is stated that if distilled water which has been shaken with air be left in contact with a piece of bright iron, and tested after 40 seconds with potassium ferricyanide, a blue coloration is immediately produced. Iron dissolves to a clear liquid in a saturated solution of carbonic acid; on boiling, a green precipitate of ferrous carbonate is produced. It is stated that, in presence of air, a definite weight of carbonic acid will exert a greater corrosive influence on iron than will an equivalent quantity of hydrochloric acid or sulphuric acid.

The inhibiting effect of certain substances on the rusting of iron, cannot be due to the fact that they are capable of decomposing hydrogen peroxide as suggested by Dunstan, since some compounds, such as potassium iodide, which destroy hydrogen peroxide, do not prevent, but actually accelerate, rusting. The formation of hydrated ferric oxide, $Fe_2O_2(OH)_2$, by the action of hydrogen peroxide on iron, as observed by Dunstan, was probably due to the use of hydrogen peroxide containing some free acid. If a piece of bright iron be placed in distilled hydrogen peroxide (free from acid), diluted to 20-volume strength with distilled water, the surface of the metal becomes covered with bubbles of gas and a steady evolution of oxygen takes place, but no brown oxide of iron is formed, nor does the metal alter in weight.—A. S.

Brasses; Special ——. L. Guillet. Comptes rend., 1906, **142**, 1047—1049.

Brasses containing between 55 and 63 per cent. of copper can be forged hot; all those containing more than 60 per cent. of copper can be forged cold. Those containing more than 63 per cent. of copper contain but one solution (Shepherd's α), while those between 55 and 63 per cent. contain also a solution β; this latter is then characteristic of those brasses which can be forged hot.

When another metal is added to the copper and zinc, it alters the mechanical properties, always in such a way that a simple brass (containing only copper and zinc) can be found which resembles in mechanical properties the alloy in question. The percentage of copper or zinc in this simple brass is called by the author the "imaginary" percentage in the alloy; and for every metal there exists a "coefficient of equivalence," t, representing the percentage of zinc for which 1 per cent. of the metal will in this sense form a substitute. Thus if an alloy contain A per cent. of copper, B per cent. of zinc, and q per cent. of the third metal, and if A′ and B′ be the "imaginary" percentages of copper and zinc, then

$$B' = (B+tq).\frac{100}{A+B+tq}, \text{ and } A' = \frac{100\ A}{100+q\ (t-1)},$$

so that A′ and B′ can be calculated if t be known. It will be seen that the imaginary percentage of copper is greater or less than the real percentage according as t is less or greater than 1. The author has determined t for several metals as follows :—

Aluminium	6·0	Lead	1·0
Silicon	10·0	Iron	0·9
Tin	2·0	Cadmium	1·0
Manganese	0·5		

The resemblance of the alloy in mechanical qualities to the simple brass having the corresponding imaginary constitution holds in the case of each element only up to a certain limiting percentage—so long, in fact, as the new element enters into the solutions which would exist were it not present. As soon as its quantity is such that a new constituent appears in the metal, the mechanical qualities of the alloy at once deteriorate.—J. T. D.

Russian metal production. Eng. and Min. J., May 5, 1906.

The output of gold in Russia during 1905 was 30,365·7 kilos. valued at 20,179,232 dols., as compared with 37,700 kilos. valued at 25,075,358 dols. in 1904. The decrease of 24 per cent. is accounted for by the disturbed condition of the Empire during the past year.

The output of silver in 1905 was 3902·7 kilos. valued at 75,722 dols., as compared with 5379 kilos. worth 100,300 dols. in 1904.

The production of mercury in 1905 amounted to 317,800 kilos. equivalent to 9347 American flasks, as compared with 331,793 kilos. (9759 flasks) in 1904.

The platinum obtained in Russia during the last two years came from the following districts :—

	1904.	1905.
	kilos.	kilos.
Tcherdinsk	153·6	125·4
Perm	1107·1	1221·0
South Verkhotoorsk	3538·5	3586·9
North ,, ...	207·3	311·6
South Ekaterinburg	5·6	46·4
Total Russia	5012·1	5241·3

The 1905 output was equivalent to 168,508 troy oz., as compared with 161,131 troy oz. in the preceding year. [T.R.]

Gold Mining in Formosa. For. Off. Misc. Ser., No. 649.

The gold output of the Formosan quartz mines, for the past five years, compared with that of the gold mines, is shown in the following table :—

Year.	Quantity.		
	Quartz mining.	Placer mining.	Total.
	oz.	oz.	oz.
1901.....	18,735	15,409	34,144
1902.....	27,893	20,424	48,317
1903.....	29,605	9,239	38,844
1904.....	48,342	5,126	53,468
1905*.....	62,730	3,447	66,177

* Estimated.

The Formosa mines are three in number, namely, the Fujita Company's mine at Kyufun, the Tanaka mine at Kinkwaseki and the Kimura mine at Botanko; the area, in square miles, occupied by each of the mines is as follows:—Fujita 4, Tanaka 3 and Kimura 1. The Fujita mines are several hundred feet above sea-level. About 2,700 tons of ore are treated on an average per month, from which 2,150 oz. of alloy, 70 per cent. gold and 30 per cent. silver, are obtained. In other words, the gold varies from 1½ to 2 in 100,000, although in 1900, when it is true only 3 tons a day were dressed, the average was 5 in 100,000. The refining processes employed are amalgamation with mercury and the cyanide process. No stamps are used as the ore is of such a clayey nature as to render them unnecessary. The machinery is driven by a steam engine of 70 horse-power and a Pelton water wheel of 150 horse-power. Water is generally abundant, the Kelung district being one of the most rainy places in the world, with a rainfall of 150 inches, while coal is abundant and cheap.

The Tanaka mines are situated at Kinkwaseki to the eastward of the Fujita company's property; one lies on the seaward side of Kinkwaseki Mountain and the other on the Botanko side. These mines are connected with the mills by a double set of overhead conveyors, the longer one exceeding 7,200 feet in length. The treating process is conducted in five separate buildings, which have been erected from time to time to cope with the increased output, which at present is slightly over 2,000 oz. per month. More than three-fourths of this total is obtained from the amalgamation process, and contains 85 to 90 per cent. of gold, while the remainder, being the tailings treated with cyanide, yield 45 per cent. of gold and over 50 per cent. of silver. The slimes are not treated yet, but it is estimated that about 600 oz. could be obtained from them. The amount of ore dressed has increased considerably of late and is at present about 2,500 tons per month, the proportion of gold now being 5 in 100,000 whereas a few years ago it was as high as 2 in 10,000. Owing to the hard nature of the ore, stamps are used here, their number being 10 of 800 lb. each in one mill and 50 of 600 lb. each in another, while in addition there are two Huntington mills. The working expenses of the mine and mills are said to be about 4,500*l.* a month, and the figures regarding some of the necessary articles imported are as follows: Potassium cyanide, 2,000 to 3,000 lb. a month, costing 10½*d.* per lb. delivered at the mines; mercury costing 9*l.* a flask, about four flasks full a month are lost in treating the gold; while the monthly consumption of zinc is 825 lb.

To the south of the other two mines, in the angle formed by them, lies the Botanko mine, which, though far the smallest of the three, is said to contain the richest ore. At present the refining plant is nothing like large enough to cope with the amount of ore extracted. Of a monthly total of 1,800 tons extracted, 1,000 tons are dressed in the mill yielding 1,100 oz. of alloy, of which 90 per cent. is gold. The tailings are not treated yet but are deposited below the mill. A few months ago an exceptionally heavy fall of rain caused the retaining walls to break down and about 40,000*l.* worth of these tailings were swept away.

The new plant will consist of four crushers of 8 horse-power and eight of 2 horse-power, 12 Huntington mills, eight batteries of 5 stamps (800 lb. weight) with a proportionate amount of amalgamated copper plates, settlers, Wilfley concentrators, spitzkasten, storage tanks, leading vats (which will number 13, 5 feet in depth and 30 feet in diameter), gold solution tanks and zinc boxes. [T.R.]

Parting apparatus; New form of platinum ——. A. Jarman. XXIII., page 561.

Babbitt [anti-friction] metal; Rapid method for the analysis of ——. H. Yockey. XXIII., page 562.

English Patents.

Ores containing nickel; Treatment of ——. R. W. E. MacIvor and M. Fradd, London. Eng. Pat. 6255, March 24, 1905.

Sulphide ores containing arsenic, antimony or both are "dead" roasted in a suitable furnace, ground fine and mixed with from 25 to 50 per cent. of a sodium polysulphide and not more than 5 per cent. of carbon. The mixture is maintained at a strong red heat in a muffle, thus producing a matte which is subsequently converted by slow roasting to sulphates which are finally separated by known wet methods.—J. H. C.

Ores: Treatment of ——. H. H. Lake, London. From D. Baker and W. W. Hearne, Wayne, Pa., U.S.A. Eng. Pat. 9007, April 28, 1905.

See U.S. Pat. 788,813 of 1905; this J., 1905, 624.—T. F. B.

Kilns; Calcining ——. J. Prosser and D. Upton, Jarrow. Eng. Pat. 14,571, July 14, 1905.

The kilns arranged in continuous rows, and having a series of ore and fuel bins on each side, are built of square or rectangular form, with hopper bottoms supported clear of the ground, and provided with shoots closed by sliding doors operated by racks and pinions, whereby the calcined mineral may be discharged into cars or trucks running on straight tracks beneath the kilns.
—J. H. C.

Iron; Process of extracting —— from its ores. C. G. P. de Laval, Stockholm. Eng. Pat. 14,574, July 14, 1905.

See Fr. Pat. 356,098 of 1905; this J., 1905, 1311.—T.F.B.

Furnaces [for heating iron and steel]; Impts. in ——. A. Allen, Rotherham, Yorks. Eng. Pat. 15,024, July 21, 1905.

In reverberatory furnaces in which a portion of the waste gases is caused to return along a flue from the rear to the front end of the hearth, the opening into the return flue passes vertically upwards and has its rear wall built continuous with the plain end wall of the furnace above the entrance to the chimney flue. The object is to obtain a continuous circulation of a portion of the gases.
—W. H. C.

Roasting and desulphurising furnaces; Mechanical ——. H. Howard, Brookline, U.S.A. Eng. Pat. 21,762, Oct. 26, 1905.

See Fr. Pat. 358,977 of 1905; this J., 1906, 321.—T. F. B.

Slag; Process for disintegrating basic ——. T. Kalinowsky, Biebrich-on-Rhine, Germany. Eng. Pat. 24,655, Nov. 28, 1905. Under Int. Conv., Jan. 28, 1905.

See Fr. Pat. 360,806 of 1905; following these.—T. F. B.

Metal; Manufacture of a material for cleaning and protecting —— especially suitable for cleaning gun barrels and protecting them from rust. J. Y. Johnson, London. From Saponia-Werke Ferd. Boehm, Offenbach-on-Maine, Germany. Eng. Pat. 25,976, Dec. 13, 1905.

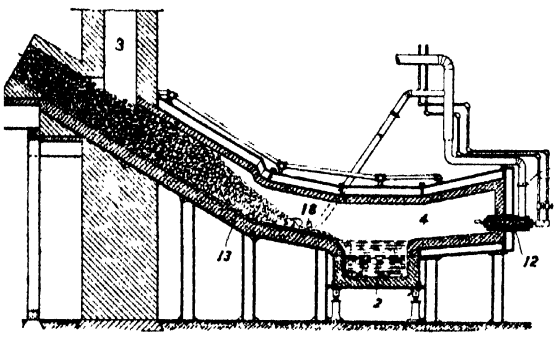
See Fr. Pat. 360,500 of 1905; this J., 1906, 482.—T. F. B.

United States Patents.

Smelting and refining process ——. E. C. Pollard, Seattle, Wash. U.S. Pat. 813,824, Feb. 27, 1906.

Copper ores containing sulphur are melted in presence of a suitable flux into a matte, which is subsequently bessemerised. During this process, a stream of silicious slag is made to pass over the molten matte so as to absorb the products of the blast, the still fluid slag is then brought into contact with silicious material and ferrous sulphide, whereby any copper present is reduced to subsulphide in a portion of the stream, which portion is then returned for use with a fresh portion of molten matte.—J. H. C.

Patterns; Process for applying powder to ——. F. Damhorst, A. Kemper and E. Utke, all of Berlin. U.S. Pat. 815,297, March 13, 1906.



A powder, such as calcium carbide or lime, capable of generating a gas or steam in contact with water in the moulding-sand, is mixed with an anhydrous liquid, such as petroleum, and the mixture is sprayed on to the pattern

The spray adheres better than the dry powder, and gives a smoother casting.—B. N.

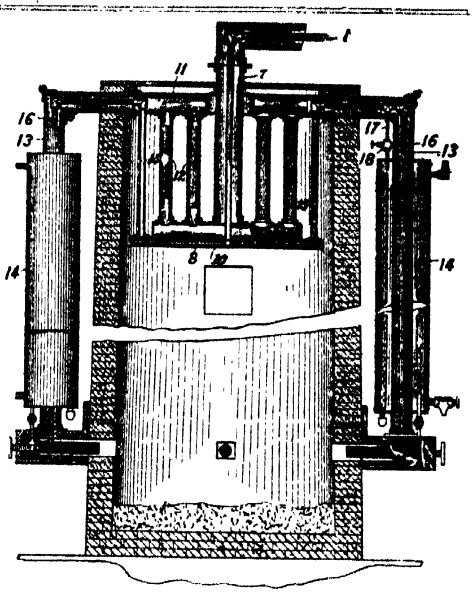
Ore-roaster. J. W. Boileau, Assignor to L. C. Sherwood, Detroit, Mich. U.S. Pat. 820,088, May 8, 1906.

A ROTARY tapering retort is mounted horizontally in a cylindrical casing, having a combustion chamber at one end, below the small end of the retort; the products of combustion pass through the annular space between the casing and the retort. Two rectangular gas-generators are arranged at opposite sides of the combustion chamber, one wall of each generator being constituted by a wall of the combustion chamber. The gas produced in the generators passes through pipes into a conduit extending centrally through the retort, and having openings through which the gas is discharged into the interior of the retort, for the purpose of "chemically treating" the material being roasted.—A. S.

Smelting ores; Furnace for and process of ——. E. Riveroll, Los Angeles, Cal. U.S. Pats. 820,133 and 820,134, May 8, 1906.

THE ore is fed into the upper end of the inclined shoot, 13, down which it travels by gravity until it reaches the lower and less inclined part, where its movement is arrested. At the lower end, the shoot communicates with the closed combustion chamber, 4, into which fuel and air under pressure are introduced through the burner, 12. The hot blast passes upwards through the body of ore, and the gases escape into the stack, 3; a supplementary blast of air is introduced through the pipe, 18. The fused ore flows into the well, 2, where separation of the metal and slag takes place.—A. S.

Ore roasting furnace. I. Sanfilippo, Casteltermini, Italy. U.S. Pat. 820,138, May 8, 1906.



SEE Fr. Pat. 334,444 of 1903; this J., 1904, 67.—T. F. B.

Cupola. W. S. Anderson, Cincinnati, Ohio. U.S. Pat. 820,167, May 8, 1906.

THE patent relates to a cupola heated by means of liquid fuel. The fuel-supply pipe passes round the cupola and is provided with communicating "pipe-spurs" which project inwards, and are embedded in the wall of the cupola, in order to derive heat therefrom and so preheat the fuel. The fuel passes from this heating pipe to burner-nozzles which discharge into the cupola.—A. S.

Cupola. J. H. Koons, Delphos, Ohio. U.S. Pat. 820,210, May 8, 1906.

THE patent relates to a heating apparatus for a cupola. A low-pressure air-pipe, 7 (see Fig.), passes through the top of the cupola and has upper and lower branch pipes, 11, and, 8, respectively, with connecting pipes, 12. From the upper branch pipes, low-pressure pipes, 13, pass through oil-tanks, 14, to the tuyère-boxes at the lower portion of the cupola. A high-pressure air-pipe, 1, passes through the low-pressure pipe, and has branch pipes, 10, from which vertical pipes, 15, rise and connect with high-pressure pipes, 16, which also pass through the oil-tanks to the tuyère-boxes. Air-supply pipes, 17, controlled by valves, 18,

lead from the high-pressure pipes into the upper portions of the oil-tanks. The oil in the tanks is heated by means of steam-pipes, and independent supplies of oil and of heated air under high and low pressure respectively pass to the burners.—A. S.

FRENCH PATENTS.

Ores; Apparatus for the concentration of ——. P. H. L. Combres. Fr. Pat. 360,401, Aug. 12, 1905.

THE invention relates to a jigging arrangement suitable for prospectors or small mines, and consisting of a peculiarly constructed sieve working in water, contained in a partitioned trough, and so suspended as to secure both vertical and horizontal motions, whereby concentration of the heavier material is obtained, the waste being discharged at intervals as desired.—J. H. C.

Ores; Concentration of poor —— with calcareous matrix. J. de Coppet. First Addition, dated Oct. 21, 1905, to Fr. Pat. 358,089, Oct. 6, 1905 (this J., 1906, 270).

THE lime is dissolved from a mixture of lime and finely pulverised metallic oxide, suspended in water, by means of dilute acid, used in such proportion that an alkaline reaction is constantly shown by means of a small quantity of an alcoholic solution of phenolphthalein which is added at the outset.—J. H. C.

Zinc; Furnaces or apparatus suitable for the manufacture of ——. J. Armstrong. Fr. Pat. 361,023, Sept. 15, 1905.

SEE Eng. Pat. 20,543 of 1904; this J., 1905, 1113.—T.F.B.

Metals and alloys; Process and apparatus for the refining of ——. Super-refining Metallurgists, Ltd. Fr. Pat. 360,408, Oct. 23, 1905.

THE apparatus comprises a closed crucible heated by a furnace which is mounted on trunnions so that it can be tilted. The crucible communicates by means of flexible tubing with two or more vacuum chambers and a suction pump, and the furnace is connected to a blower, also by means of flexible tubing. The metal or alloy to be refined is heated *in vacuo* in the closed crucible, and is kept agitated by the oscillation of the furnace. For the purpose of making alloys the crucible may be divided into compartments by partitions extending upwards to about one-third of the height of the crucible. The components of the alloy are melted in separate compartments and are then mixed by tilting the furnace. The cover of the crucible

may have (1) a mould attached to it, which on tilting the furnace becomes filled with the molten metal, and (2) may also be provided with valved receptacles containing substances (deoxidising or desulphurising agents) which it is desired to add to the molten metal.—A. S.

Autoclaves; Employment of —— in metallurgy for the treatment of minerals and the separation of metals. L. Rivière. Fr. Pat. 360,602, Nov. 18, 1905. Under Int. Conv., May 2, 1905.

THE powdered minerals are treated in an autoclave under pressure of steam greater than that of the atmosphere, with caustic alkali, alkali carbonate or alkali sulphide. The solutions thus obtained are afterwards similarly treated with lime whereby the dissolved metallic oxides or salts are separated and the alkaline solutions are regenerated.—J. H. C.

Slags from the Thomas process [Basic slag]; Pulverisation of ——. T. Kalinowski. Fr. Pat. 360,806, Nov. 27, 1905. Under Int. Conv., Jan. 28, 1905.

THE molten slag, while at a white heat, is received in a closed receptacle, provided with a safety valve, and is showered with water, the steam thus produced under high pressure effecting the desired pulverisation.—E. S.

Minerals; Treatment of —— for the extraction of metals or metallic oxides. M. A. Eybert and C. P. Eybert. Fr. Pat. 360,520, Dec. 15, 1905.

ALKALI sulphides or polysulphides are added to the finely crushed minerals in suitable proportions together with carbon. The mixture is heated in a crucible or a reverberatory or other furnace to a temperature which may vary from 600° up to 1000° C., according to the nature of the mineral, whereby the metals are separated, whilst certain oxides are volatilised. Part of the sulphur employed may be subsequently recovered by heating the residues with carbon, sodium carbonate and chalk.
—J. H. C.

Ores; Process for agglomerating friable or pulverulent ——. J. E. Goldschmid. Fr. Pat. 360,576, Dec. 18, 1905.

THE "fines" are placed in a revolving furnace and treated with jets of flame resulting from a mixture of gas and compressed air; a temperature of at least 1000° C. is thus obtained in a strictly limited zone of the furnace, whereby the ore is effectually agglomerated.
—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 485.)

(*A.*)—ELECTRO-CHEMISTRY.

Colloidal solutions; Electrical preparation of ——. T. Svedberg. Ber., 1906, **39**, 1705—1714.

By passing the discharge from a powerful induction coil between metallic electrodes in a suitable liquid, the disintegrated metal is obtained in the form of a colloidal solution. Normal propyl and isobutyl alcohols, anhydrous acetone and paraldehyde have so far proved the most suitable liquids for the purpose. Ether-alcohol gives very unstable solutions, but their stability can be greatly increased by either adding a few drops of a slightly dissociated electrolyte with heavy positive ion, such as monochlorobenzene, or working at a low temperature (—84° C.). A list of the colours of colloidal solutions of many metals and some metalloids, thus obtained, as well as experimental details, are given in the paper.—J. T. D.

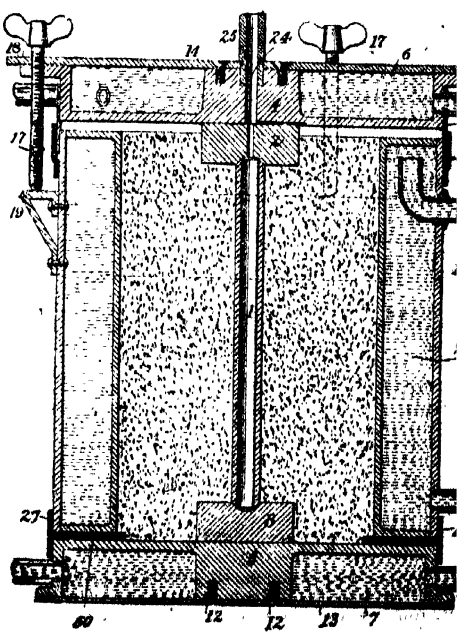
ENGLISH PATENTS.

Furnaces; Impts. in electric ——. T. Parker, London. Eng. Pat. 5721, March 18, 1905.

A CRUCIBLE of any desired shape is mounted or laid within a seating or receptacle of refractory non-conducting material, and around the inside of the receptacle is embedded a conductor, or the latter may be placed in suitable grooves, so that the exposed surface of the conductor is in contact with the crucible. The terminals of the conductor are connected to iron rings, which encircle the receptacle near its lower end. The receptacle is placed within a fire-clay base, the rings on the outside of the receptacle making contact with corresponding rings on the inside of the base, the latter rings being attached to the source of current. The base has a projecting seat for partially supporting the receptacle thus preventing the whole of the weight of the latter from falling upon the inclined contact rings. An air space is provided between the outer and inner surfaces of the receptacle and base.—B. N.

Nitrogen-oxygen compounds; Process of producing —— by means of electricity. Westdeutsche Thomasphosphatwerke, Berlin. Eng. Pat. 8721, April 25, 1905. Under Int. Conv., April 7, 1905.

SEE Fr. Pat. 353,548 of 1905; this J., 1905, 1013.—T.F.B



Ozonising apparatus; Impts. in [Electrical] ——. H. J. Wessels de Frise, Paris. Eng. Pat. 8836, April 26, 1905. Under Int. Conv., April 26, 1904.

THE object of this invention is to diminish or completely suppress the decomposition of ozone in the apparatus in which it is formed. The elements of a suitable shape forming one of the electrodes are alternately superposed with the elements forming the other electrode, and a central suction tube is provided at intervals with suitable openings so that the air is drawn out of the apparatus at different levels, thus avoiding the passage of the ozonised air through several electric discharges. A second form is described in which the air enters through slots between the elements of one electrode, and passes in a zig-zag manner to corresponding slots between the elements of the second electrode, the latter slots being in connection with a vacuous reservoir.—B. N.

UNITED STATES PATENTS.

Furnace; Vacuum electric ——. H. N. Potter, New Rochelle, N.Y., Assignor to G. Westinghouse, Pittsburg, Pa. U.S. Pat. 814,726, March 13, 1906.

A TUBE, 1, of graphite or carbon, constitutes the core of the furnace, and the material to be treated is placed

around it. At the ends of the core are arranged terminal blocks, 2 and 3, of graphite or other conducting refractory material, and these make contact with metallic terminals, 4 and 5. The core may be in the form of a rod with rounded ends fitting into corresponding depressions in 2 and 3, the surfaces being ground so as to make good contact; or, if in the form of a tube, the core may have solid rounded end portions, with suitable vent holes in the tube or in the solid end portions. The contacts, 4 and 5, are water-jacketed, and copper plates, 13, 14, are attached by the screws, 12, and also by soldering to the contacts. The upper terminal portion is supported by screws, 17, the latter passing through the extension, 18, and resting on brackets, 19, attached to the furnace body, 16. This prevents the atmospheric pressure on 14 from bending the heated core when the furnace is exhausted. A cylindrical metal tube, 15, with thin walls, slips over the furnace body, 16, and a rubber band 20, prevents entrance of air. The terminal, 4, may thus be adapted to cores of different lengths. The furnace body consists of a tube, 16, with double walls having an annular water-jacket, 21, provided with inlet, 22, and outlet, 23, and the furnace body rests on an insulating ring, 60, of asbestos or mica, a rubber band, 27, making an air-tight joint. A tube, 25, connected to the vacuum pump, is screwed into the block, 4, the bore of the tube being the same as the opening, 24. At the bottom of the block, 4, a groove or channel is cut to connect the tube, 24, with the interior of the furnace, or, in the case of a tubular core, the block, 2, may be perforated. The water-jackets, 6 and 21, may be connected in series, but the jacket, 7, is supplied from a separate source, in order to avoid electrolysis.—B. N.

Liquids; Apparatus for treating —— [electrically]. L. Dion, New York, Assignor to the Americus Electro-Hermatic Co., New York. U.S. Pat. 819,209, May 1, 1906.

A VESSEL or reservoir is constructed with an enlarged globular portion and a lower contracted portion, a group of positive and negative electrodes being arranged within the latter. The electrodes are constructed in "prismoidal form angularly bent transversely of their axes," and are arranged in vertical rows forming vertical and horizontal portions, the longitudinal section of each being rectangular, and the cross-section in the form of an equilateral triangle. One end of each electrode is connected to a base plate, means being provided for supplying a current of electricity to the electrodes. Means are also provided for supplying a liquid through the bottom of the vessel, and between the electrodes.—B. N.

"Super-heating compound" [for use in the manufacture of carbide]. H. L. Hartenstein, Chicago, Ill., Assignor to Electro Chemical and Development Co., Pierre, South Dakota. U.S. Pat. 819,218, May 1, 1906.

A MIXTURE is made of the following substances in a pulverised or granulated condition: calcium carbide, carbon such as bituminous coal, substances producing oxygen such as manganese dioxide and potassium chlorate, and a metallic element such as aluminium. (See U.S. Pat. 819,222, below.)—B. N.

Carbide; Manufacture of —— [electrically]. H. L. Hartenstein, Chicago, Ill., Assignor to Electro Chemical and Development Co., Pierre, South Dakota. U.S. Pat. 819,219, May 1, 1906.

THE material containing lime is mixed with a small quantity of carbon, and fused, the molten mass being then run into a heated mould coated with powdered carbon, the latter completing the conversion of any metallic particles into carbide.—B. N.

Carbide; Method of producing —— [electrically]. H. L. Hartenstein, Chicago, Ill., Assignor to Electro Chemical and Development Co., Pierre, South Dakota. U.S. Pat. 819,220, May 1, 1906.

LIME and carbon, containing elements to reduce the mass to a molten condition, are first fused, and the molten mass run off into thin sheets so as to chill it.—B. N.

Carbide; Process in the production of ——. H. L. Hartenstein, Chicago, Ill., Assignor to Electro Chemical and Development Co., Pierre, South Dakota. U.S. Pat. 819,221, May 1, 1906.

THE molten mass of carbide is allowed to flow directly from the furnace into a heated mould, the internal surface of which has been coated with a material impervious to water, such as tar mixed with powdered coke. The carbide is thus uniformly coated with a protective layer, and superficially impregnated with the tar whilst in a fluid and incandescent state.—B. N.

Carbide; Manufacture of —— [electrically]. H. L. Hartenstein, Chicago, Ill., Assignor to Electro Chemical and Development Co., Pierre, South Dakota. U.S. Pat. 819,222, May 1, 1906.

PULVERISED limestone, in the presence of carbonaceous material, such as powdered coke, is calcined, the mass being agitated during the operation in order to intimately mix the substances. The mass is then superheated to incandescence by the addition to the calcined heated mass of a super-heating mixture or flux, such as is described in U.S. Pat. 819,218 (see abstract above), in order to drive off any phosphorus in the heated mass. The latter is finally fused whilst still in a highly-heated condition.
—B. N.

Lining for electric or other furnaces and method of preparing the same. H. L. Hartenstein, Chicago, Ill., Assignor to Electro Chemical and Development Co., Pierre, South Dakota. U.S. Pat. 819,223, May 1, 1906.

CREAM of lime and powdered coke are mixed together, and asbestos, together with a powdered hydrocarbon, is then added. The mass is formed into non-combustible bricks, blocks or slabs, which are finally pressed and dried.
—B. N.

Furnace; Electric ——. H. L. Hartenstein, Chicago, Ill., Assignor to Electro Chemical and Development Co., Pierre, South Dakota. U.S. Pat. 819,224, May 1, 1906.

THIS invention relates to an electric furnace comprising an upper hopper or casing, carrying a smoke-stack and a pair of electrodes, and a lower member or furnace chamber located beneath the casing. The furnace chamber may be moved laterally by a truck, a pressure device elevating the chamber against the upper casing. The electrodes project into, but out of contact with, the furnace chamber, each electrode being provided with a support which passes through a slot in the hopper or casing. The support passes loosely through a "slide-guide" which is arranged to move along the slot, and a flexible cover is connected with the "slide-guide" for closing the slot in whatever position the support is adjusted. Mechanism is provided within the upper casing for tilting and adjusting the electrodes in a longitudinal, lateral or rotary direction, and also a means for adjusting the extent of projection of the electrodes into the furnace chamber in order to facilitate the removal of the latter.—B. N.

Carbon [for electrical purposes]; Apparatus for producing ——. T. P. Sharts, Readsboro, Vt., Assignor to C. J. Howe, Jamaica, Vt., W. C. Davis and J. H. Cole, Readsboro, Vt. U.S. Pat. 819,606, May 1, 1906.

THIS invention relates to an apparatus for producing charcoal carbon for electrical purposes, and comprises a combustion chamber having a lateral outlet opening directly into the atmosphere for the escape of some of the products of combustion. A burner is mounted in one wall of the furnace for blowing a jet of hydrocarbon oil, such as petroleum, and air into the chamber, and a movable wall, with a plastic sealing material for holding it in position, is fixed opposite the burner. The sealing material ensures the closing of all crevices, and permits of the collection of the carbonaceous products of the combustion in a hard homogeneous mass upon the inner face of the wall. The latter may be set back from the burner from time to time, in order to thicken the collection of carbon on the wall in successive layers.—B. N.

may have (1) a mould attached to it, which on tilting the furnace becomes filled with the molten metal, and (2) may also be provided with valved receptacles containing substances (deoxidising or desulphurising agents) which it is desired to add to the molten metal.—A. S.

Autoclaves; Employment of —— in metallurgy for the treatment of minerals and the separation of metals. L. Rivière. Fr. Pat. 360,602, Nov. 18, 1905. Under Int. Conv., May 2, 1905.

THE powdered minerals are treated in an autoclave under pressure of steam greater than that of the atmosphere, with caustic alkali, alkali carbonate or alkali sulphide. The solutions thus obtained are afterwards similarly treated with lime whereby the dissolved metallic oxides or salts are separated and the alkaline solutions are regenerated.—J. H. C.

Slags from the Thomas process [Basic slag]; Pulverisation of ——. T. Kalinowski. Fr. Pat. 360,806, Nov. 27, 1905. Under Int. Conv., Jan. 28, 1905.

THE molten slag, while at a white heat, is received in a closed receptacle, provided with a safety valve, and is showered with water, the steam thus produced under high pressure effecting the desired pulverisation.—E. S.

Minerals; Treatment of —— for the extraction of metals or metallic oxides. M. A. Eybert and C. P. Eybert. Fr. Pat. 360,520, Dec. 15, 1905.

ALKALI sulphides or polysulphides are added to the finely crushed minerals in suitable proportions together with carbon. The mixture is heated in a crucible or a reverberatory or other furnace to a temperature which may vary from 600° up to 1000° C., according to the nature of the mineral, whereby the metals are separated, whilst certain oxides are volatilised. Part of the sulphur employed may be subsequently recovered by heating the residues with carbon, sodium carbonate and chalk.
—J. H. C.

Ores; Process for agglomerating friable or pulverulent ——. J. E. Goldschmid. Fr. Pat. 360,576, Dec. 18, 1905.

THE "fines" are placed in a revolving furnace and treated with jets of flame resulting from a mixture of gas and compressed air; a temperature of at least 1000° C. is thus obtained in a strictly limited zone of the furnace, whereby the ore is effectually agglomerated.
—J. H. C.

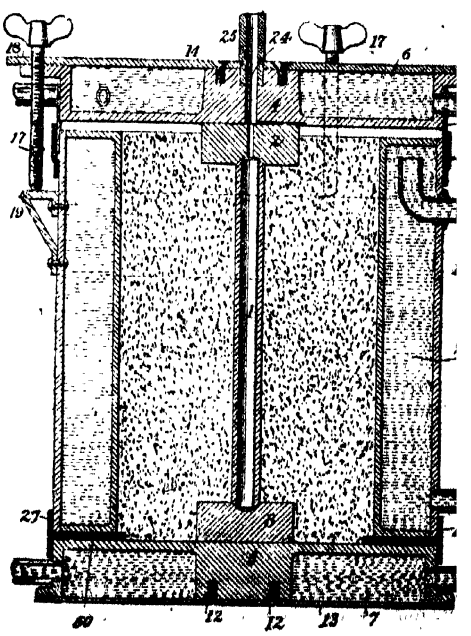
ENGLISH PATENTS.

Furnaces; Impts. in electric ——. T. Parker, London. Eng. Pat. 5721, March 18, 1905.

A CRUCIBLE of any desired shape is mounted or laid within a seating or receptacle of refractory non-conducting material, and around the inside of the receptacle is embedded a conductor, or the latter may be placed in suitable grooves, so that the exposed surface of the conductor is in contact with the crucible. The terminals of the conductor are connected to iron rings, which encircle the receptacle near its lower end. The receptacle is placed within a fire-clay base, the rings on the outside of the receptacle making contact with corresponding rings on the inside of the base, the latter rings being attached to the source of current. The base has a projecting seat for partially supporting the receptacle thus preventing the whole of the weight of the latter from falling upon the inclined contact rings. An air space is provided between the outer and inner surfaces of the receptacle and base.—B. N.

Nitrogen-oxygen compounds; Process of producing —— by means of electricity. Westdeutsche Thomasphosphatwerke, Berlin. Eng. Pat. 8721, April 25, 1905. Under Int. Conv., April 7, 1905.

SEE Fr. Pat. 353,548 of 1905; this J., 1905, 1013.—T.F.B



Ozonising apparatus; Impts. in [Electrical] ——. H. J. Wessels de Frise, Paris. Eng. Pat. 8836, April 26, 1905. Under Int. Conv., April 26, 1904.

THE object of this invention is to diminish or completely suppress the decomposition of ozone in the apparatus in which it is formed. The elements of a suitable shape forming one of the electrodes are alternately superposed with the elements forming the other electrode, and a central suction tube is provided at intervals with suitable openings so that the air is drawn out of the apparatus at different levels, thus avoiding the passage of the ozonised air through several electric discharges. A second form is described in which the air enters through slots between the elements of one electrode, and passes in a zig-zag manner to corresponding slots between the elements of the second electrode, the latter slots being in connection with a vacuous reservoir.—B. N.

UNITED STATES PATENTS.

Furnace; Vacuum electric ——. H. N. Potter, New Rochelle, N.Y., Assignor to G. Westinghouse, Pittsburg, Pa. U.S. Pat. 814,726, March 13, 1906.

A TUBE, 1, of graphite or carbon, constitutes the core of the furnace, and the material to be treated is placed

ENGLISH PATENT.

Furnaces; Electric ——. Soc. Anon. Electrometallurgique (Procédés P. Girod), Ugine, Switzerland. Eng. Pat. 25,174, Dec. 4, 1905. Under Int. Conv., Jan. 4, 1905.

Matte; Treating molten ——. W. E. Koch, Pittsburg, Pa. U.S. Pat. 808,849, Jan. 2, 1906.

THE stream of molten matte is passed between electrodes, preferably of graphitised carbon, gases being simultaneously forced through it, whereby the iron and copper present are separated from each other and diverted by means of a "splitter."—J. H. C.

FRENCH PATENTS.

Furnace; Electric ——. P. Girod. Fourth Addition, dated Nov. 28, 1905, to Fr. Pat. 329,822, Feb. 28, 1903 (this J., 1903, 1054; 1904, 740 and 1179).

To insure uniform heating in the annular layer of resistance material surrounding the crucible, the conducting] material leading the current to it from the

terminals of the furnace has a special disposition. This is made clear in the figure, showing a plan of the furnace. The annular layer of resistance material, *c*, surrounding the crucible, *a*, is of uniform section, the connection to the electrodes, *d*, being made by similar material, *e*, arranged so that its cross-section gradually decreases from the electrodes to the annular layer. The cross-section also diminishes from the base to the top of the crucible which further assists in obtaining uniformity of heating.

The modification described is specially suitable for heating small crucibles containing metals or other electrically conducting materials.—R. S. H.

Ores and metals; Treatment of —— in the electric induction furnace. P. Gredt. Fr. Pat. 360,404, Aug. 31, 1905.

MOLTEN pig iron or other crude metal is heated in an induction furnace with slags containing oxide of iron, intimate admixture of the two being brought about by the pulsations due to the current. These pulsations are stronger the lower the periodicity of the alternating current. It is further advantageous to provide the induction furnace with side chambers in which the reactions can more readily take place.—R. S. H.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

(*Continued from page* 486.)

ENGLISH PATENT.

Oil and fatty matters from substances; Extraction of ——. E. Ridgill, Sheffield. Eng. Pat. 15,231, July 25, 1905.

THE substances to be extracted are packed in a vessel provided with a central vertical perforated pipe and a perforated coil through which steam can be blown. The solvent is passed through the material into another vessel provided with steam pipes. To recover the solvent, steam is passed into both the vessels, which are connected to concentric coils cooled by water. The steam distillate is collected in a well, where the solvent separates out.

—F. SHDN.

UNITED STATES PATENT.

Candle materials; Process for manufacture of ——. J. Glatz, Brooklyn. U.S. Pat. 819,646, May 1, 1906.

FATS or fatty acids are treated with ammonia under a pressure of 10—50 atmospheres for a period of 2—20 hours at temperatures ranging between 150° and 250° C.

—J. F. B.

Wood tars and resin oils; Distillation and oxidation of ——. H. Noerdlinger. Eng. Pat. 8590A, Sept. 15, 1905. III., page 529.

(*C.*)—INDIA RUBBER, &c.

Rubbers from Sierra Leone. Bull. Imp. Inst., 1906, **4**, 29—31.

THE three varieties of rubber examined had been collected in the Panguma district of the Protectorate and are known to the natives as Jenje, Gbogboi and Njawa respectively. The vine yielding Jenje rubber is closely related to *Landolphia ovariensis*, though its identity could not be definitely ascertained from the specimens received. Gbogboi rubber is derived from the tree *Funtumia elastica*, the West African rubber tree, the existence of which in Sierra Leone is a point of considerable importance. The plant yielding Njawa rubber is described as a vine, known as Sagba, but its identity is uncertain. The rubbers gave the following results on analysis, the figures expressing percentages on the dry material:—

	Jenje Rubber.	Gbogboi Rubber.	Njawa Rubber.
Caoutchouc	88·6	82·0	73·8
Resin	6·0	4·4	22·1
Albuminoid matter	2·1	2·5	3·0
Vegetable impurity	3·3	11·1	1·1
Ash	2·04	2·40	0·42
Moisture in original sample	3·2	2·1	3·6
Elasticity	good	good	poor

—W. P. S.

Carbon dioxide; Diffusion of —— through caoutchouc. Grunmach. Woch. f. Brau., 1906, **23**, 226—227.

THE author has studied the rate of diffusion of carbon dioxide through membranes of caoutchouc, ranging from 0·15 to 2·4 mm. in thickness. He found that the rate of diffusion decreased considerably in the course of several days. For instance, a plate of caoutchouc 44 sq. cm. in area and 0·6 mm. in thickness, which passed on the first day 0·021 c.c. of carbon dioxide per hour, passed only 0·003 c.c. per hour on the seventh day. With membranes of different thicknesses the rate of diffusion does not decrease in proportion to the increase of the thickness. The quality of the rubber, whether grey or red vulcanised, does not appear to have any appreciable influence. The diffusion of carbon dioxide through rubber tubes and joints, when small quantities of the gas have to be determined, is not negligible. Apparatus used for the study of the respiration of grain should have glass connections. The flasks in which the grain is stored for the subsequent determination of the carbon dioxide produced by respiration should not be closed by rubber corks, but should be sealed by fusion.—J. F. B.

UNITED STATES PATENTS.

Vulcanised material and process for making same. F. Ephraim, San Francisco. U.S. Pat. 819,529, May 1, 1906.

PLANTS containing rubber or similar gum are crushed and pulverised without separating the fibrous portions of the plants; a vulcanising substance is mixed with the powdered plant and the mixture is then vulcanised.

—J. F. B.

Whalebone or rubber substitutes; Process for producing ——. W. Polatsik, Assignor to J. L. Bloom. U.S. Pat. 820,315, May 8, 1906. XIV., page 548.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page* 488.)

Barbatimao bark; Notes on ——. J. Paessler. Collegium, 1906, 135—140; 142—145.

THE Barbatimao tree grows in Brazil and other parts of South America. The oldest trees attain a height of from 18 to 30 ft. with a diameter of from 8 to 12 ins. The bark is rich in tannin, yielding about 27 per cent. of tannin-substances and only 4 per cent. of soluble non-tannins. It has about the same tanning strength as valonia (28 per cent. of tannin) and a much higher one than quebracho (19 per cent. of tannin). The leaves and fruit are also rich in tannin, the former containing about 7 per cent. of tannin and 8 per cent. of non-tannins.

Calf skins tanned with this bark show a very bright colour, are soft and smooth-grained and take fat with ease. A very bright and even colour is also produced on sole leather, and the tanned material has a fine grain and is firm and pliable.—H. Bn.

Eutannin. H. Thoms. Sixth Int. Cong. appl. Chem. Z. angew. Chem., 1906, **19**, 804.

THE author has examined a preparation brought on the market, in admixture with milk sugar, under the name of "eutannin." The purified substance melts at about 234° C. with decomposition; it is readily soluble in alcohol and in hot water, sparingly soluble in ether and cold water, it crystallises in small needles, reddens litmus and is dextro-rotatory. The manufacturers claim that "eutannin," when heated with water at 100° C. in closed vessels, is resolved almost quantitatively into tannic acid. The author, however, fails to confirm this statement and finds that "eutannin," $C_{28}H_{22}O_{19}$, is merely converted into its hydrate, $C_{26}H_{24}O_{20}$, on heating with water. He also finds that "eutannin" is hydrolysed by caustic soda with the production mainly of gallic acid, together with dextrose and other bodies. Judging from the behaviour of the body, the author does not think that the dextrose is present in "eutannin" in the form of a glucoside. He suggests that the "eutannin" molecule is formed by the condensation of three gallic acid residues with one another, one of them being also condensed with the anhydride of hexahydroxyhexahydrobenzenecarboxylic acid. On treatment with water the anhydride is hydrated, and when the eutannin is hydrolysed by sodium hydroxide solution it is split up into 3 mols. of gallic acid, 1 mol. of hexahydroxyhexahydrobenzene and carbon dioxide. The hydro-aromatic product then undergoes isomerisation into dextrose. According to the author, "eutannin" is identical with the chebulic acid obtained from myrobolans.—J. F. B.

Tanning effect of various tanning materials; Comparative tests of the ——. V. Bögh. Collegium, 1906, 126—132; 134—135.

THIS work is an extension of that of Youl and Griffith, who investigated the tanning effect given by single tanning materials, whereas the author deals with mixtures as well as with single materials.

An unfiltered quebracho-wood infusion was found to have a much higher "weight-giving" property than that of one which had been filtered. The order in which various individual tanning materials may be arranged as regards weight-giving capacity is as follows, starting with the best:—Quebracho, birch bark (*Betula alba*), oak bark and finally pine bark (*Picea excelsa*).—H. Bn.

Sole leather; Adulteration of American ——. J. Gordon Parker, A. Turnbull and Committee, Manchester, Liverpool and District Tanners' Federation Year Book, 1906, 24—27.

A SERIES of analyses was made with the object of ascer-

taining the cause of deterioration in the wearing and water-resisting properties of American sole leather. The 18 samples taken represent the general run of American imported leather, and not specially selected cases. After making allowance for natural saccharine matter which is present to a small and varying extent in all tanning materials, it was found that the leathers contained from 3·21—30·10 per cent. of weighting matters, consisting of magnesium sulphate, glucose, and in one case of sodium sulphate.

The best specimen of leather contained 3·21 per cent. of crude glucose only, whilst the worst contained 21·99 per cent. of crude glucose, 2·99 per cent of magnesium sulphate, 4·42 per cent. of sodium sulphate, and 0·70 per cent. of sodium chloride.

The average total weighting matter amounted to 10·16 per cent. consisting of 2·03 per cent. of magnesium sulphate, and 7·84 per cent. of crude glucose. The amount of soluble matter washed out by cold water ranged from 18·42 per cent. to 33·20 per cent.—H. Br.

Leather; Water-resisting qualities of modern sole ——. J. Gordon Parker. Manchester, Liverpool and District Tanners' Federation Year Book, 1906, 62.

A number of samples of sole leather, of various qualities, were subjected to the pressure of a column of water 12 ins. high and 2 ins. in diameter, and the time noted when the water penetrated through the leather, damping it evenly throughout. Another test was that of hanging strips of leather of equal lengths with one end dipping into water, and noting how much of the leather above the water was made damp at the end of 12 hours. It was found in these experiments, that leather produced by the old method of oak bark tanning, wherein longer time was given than at present, was far more water-resisting than that tanned by more rapid methods.—H. Br.

Blackwattle bark trade of Natal. Board of Tr. J., May 24, 1906.

The quantity of blackwattle bark exported in 1905 was 17,513 tons, of a declared value of 102,666*l*., as against 15,819 tons of a declared value of 92,911*l* for the year 1904. At the beginning of the year 1905, the mallet bark competition practically upset the European markets. About 20,000 tons of this article, which is derived from the *eucalyptus occidentalis*, a tree growing in the virgin forests of Western Australia, were imported into Hamburg the chief centre of the European markets, for tanning material in general and wattle bark in particular. As the Natal wattle industry is dependent upon the Hamburg market to the extent of about four-fifths of the export, it is not surprising that, in consequence of the mallet bark competition, prices for Natal blackwattle bark receded. [T.R.]

Valonia; Determination of extraneous matter in ——. A. Turnbull. XXIII., page 563.

English Patents.

Hides; Process of treating ——. F. J. Oakes, New York. Eng. Pat. 24,488, Nov. 27, 1905. Under Int. Conv., Dec. 12, 1904.

See U.S. Pat. 798,293 of 1905; this J., 1905, 1023.—T. F. B.

Glue; Process for the purification of ——. W. Sadikoff, St. Petersburg. Eng. Pat. 24,984, Dec. 1, 1905.

United States Patent.

Whalebone or rubber substitutes; Process for producing ——. W. Polatsik, Assignor to J. L. Bloom, Chicago, Ill. U.S. Pat. 820,315, May 8, 1906.

"Animal waste" (100 parts) is immersed for about 48 hours in a bath composed of 80 parts of water and 4 parts of acetate of lime, in order to remove fatty matters. It is then treated for a further 48 hours in a bath of 80 parts of water, 2 parts of strontium chloride, and 1 part of iron sulphate, and is afterwards stretched over boards, and dried whilst under compression.—A. S.

French Patent.

Keratin [horn, hair, &c.]; Treatment of ——. [*Rendering soluble.*] J. Hofmeier. Fr. Pat. 360,895, Dec. 23, 1905.

One hundred kilos. of horn scraps, hair, &c., are treated for 10 days at the ordinary temperature with 200 kilos. of 15 per cent. hydrochloric acid. The acid is then drawn off, and the residue, after washing with water, treated with 100 kilos. of 6 per cent. sodium hydroxide solution. At the end of 24 hours, an aqueous solution of 2 kilos. of potassium permanganate is added, and the mixture allowed to stand for a further 12 hours. The residue is then washed and subjected to a pressure of 400 atmospheres. An alternative method is to pass carbon dioxide into the alkali solution, decant and evaporate the solution. The product is finally clarified by means of hydrogen peroxide or permanganate, and may be used in place of casein for a variety of purposes.—W. P. S.

XV.—MANURES, Etc.

(*Continued from page* 488.)

Beetroots; Manuring of ——. A. Kausek. Z. f. Zuckerind. Böhmen, 1906, **30**, 339—351.

A great advantage is to be derived by manuring the growing beet crop in the field during the vegetative period by the suitable application of stable drainings and similar liquid sewage. The liquid should be brought to the fields in large tanks and distributed in a special manner by sprinkling evenly between the rows of beets, but not on the plants themselves. This is done by a small iron tank mounted on a pair of wheels and provided with a valve, a main pipe and three distributing pipes, each of which can be adjusted to give three different speeds of discharge. The tank holds about 100 galls., and when drawn by an ox it can cover about 5 acres of beetroots in a day's work, allowing for 50 refillings at 5 minutes each. The drainings from an average dung heap contain 0·2 per cent. of soluble nitrogen, 0·46 per cent. of potash, and 0·08 per cent. of chlorine; according to requirements, the liquid may be fortified by nitrate or by potash. Proper measures must be taken to collect all the drainage of the farm in underground pits, solid fæcal matters can be liquefied by the addition of quicklime and dilute sulphuric acid. Manuring with liquid sewage of this kind is equivalent to the application of nitrate; the beets absorb the whole of the fertilising matters rapidly, and yield an immediate return in the form of improved quality and quantity. The utilisation of these liquids is very important for European agriculture, since the available mineral supplies of nitrates are rapidly becoming exhausted.—J. F. B.

Nitrogen; Assimilation of elementary —— by azotobacter and radiobacter. J. Stoklasa. 6th Int. Cong. Appl. Chem.; Z. angew. Chem., 1906, **19**, 803.

Azotobacter chroococcum has a greater power of assimilating atmospheric nitrogen than any species yet studied. The culture media may contain either mannitol or dextrose. In the latter case, it is always necessary to add a little chalk. The author is unable to confirm Beijerinck's statements that *radiobacter* has any appreciable power of assimilating atmospheric nitrogen, and that *azotobacter* in co-operation with *radiobacter* has a greater assimilating power than in pure cultures; in fact, the fixation of nitrogen was less in the mixed cultures. *Radiobacter* is a powerful denitrating organism; it reduced 70—79 per cent. of the total nitrogen offered to it in the form of nitric acid to the state of free nitrogen, nitrous acid being an intermediate stage, and it fixed 10—18 per cent. of the total nitrogen (as nitric acid) in the form of organic bodies, chiefly nucleo-proteids. The author has studied the quantities of carbon dioxide evolved by the respiration of *azotobacter* during the assimilatory process. The

greatest intensity of respiration took place between the 4th and the 10th days. The average quantity of carbon dioxide produced by 1 grm. of *azotobacter* dry substance in 24 hours was 1·27 grms., which is a higher proportion than with any of the other species; *B. Hartlebi* gave only 0·6 grm. of carbon dioxide per grm., and *Clostridium gelatinosum* only 0·48 grm. under the same conditions. *Azotobacter*, when grown in mannitol or dextrose media, produces alcohol, lactic, acetic, butyric and formic acids, the gaseous products being carbon dioxide and hydrogen; a large portion of the latter gas is oxidised in the nascent state. The process of assimilation of elementary nitrogen by *azotobacter* appears to be related to the respiratory process, and, in all probability, to the production of hydrogen by the bacterium.—J. F. B.

German Patents.

Manure from peat and the like; Process for the manufacture of a ——. H. S. Gerdes, jun. Ger. Pat. 165,976, Jan. 17, 1902.

Humus substances, such as peat and the like, are treated with alkali according to known methods, then mixed in the moist condition with alkali silicates or phosphates, or both, and the mixture dried and ground.—A. S.

Humus substances; Process for rendering —— soluble. H. S. Gerdes, jun. Ger. Pat. 165,228, Feb. 12, 1904.

The humus substances without addition of organic nitrogenous matter, are treated in the moist condition with alkalis or alkali carbonates or with secondary alkali phosphates, especially disodium phosphate. The mass is formed into heaps, after mixing, if desired, with silicates or phosphates, or both, and the heaps are turned over several times and allowed to remain until putrefaction takes place. The material is finally dried and ground.

—A. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Maple sugar industry; The ——. U.S.A. Dept. of Agric., Bull. 59; through Bull. Imp. Inst., 1906, **4**, 52—55.

The demand for maple sugar, as an article of luxury, is said to be increasing every year, but the competition of cane and beet sugar, bad seasons, attacks on the trees by the maple worm, and destruction of the forests by lumbermen, have caused a great shrinkage in the producing area. Considerable adulteration with glucose is also said to have been perpetrated by the mixers. The output in the year 1900 was 11,928,770 lbs., almost one-third less than in the year 1850. The sugar maple (*Acer saccharum*) and the black maple (*A. saccharum nigrum*) furnish the best sugar; a similar saccharine sap is yielded by three other American maples of less importance, the red, silver and Oregon species (*A. rubrum*, *A. saccharinum* and *A. macrophyllum*).—W. P. S.

Sugar-beet; The enzymes of the ——. J. Stoklasa. 6th Int. Congr. appl. Chem. Chem.-Zeit., 1906, **30**, 422.

The author has isolated from the beetroot enzymes characterised as oxydases, invertase and glycolytic enzymes. The glycolytic enzymes are to be regarded as respiration enzymes and they are secreted by the living protoplasm both in the normal and in the anaërobic respiration of the beetroot. They set up alcoholic fermentation in dextrose solutions, in presence of salicylic acid as an antiseptic; the fermentation frequently starts immediately and reaches its maximum intensity in 6—8 hours. The products of fermentation consist of considerable quantities of alcohol and carbon dioxide together with smaller quantities of lactic and acetic acids. After 24 hours an evolution of hydrogen is observed, even with free access of air. The breakdown of the carbohydrates probably takes place with the production of lactic acid, alcohol and carbon dioxide, but in presence of air, acetic acid is always produced. The formation of formic acid has also been observed; this acid is probably the source of the hydrogen, which is evolved together with carbon dioxide. The hydrogen, which is the end product of the breakdown of the carbohydrates is, to a large extent, oxidised in the nascent condition with formation of water. It is possible that this nascent hydrogen in the chlorophyll-bearing cells plays a part in the assimilation of carbon dioxide with production of formaldehyde and water. The enzymes of a glycolytic character present in the sugar-beet are enumerated as follows:—Lactolase (Buchner's lactacidase), which splits up the hexoses into lactic acid; alcoholase, which brings about alcoholic fermentation; acetolase (Buchner's glucacetase) which causes the formation of acetic acid, and formilase which produces formic acid.—J. F. B.

Dextrose and levulose; Influence of dilution and the presence of other sugars on the osazone test for ——. H. C. Sherman and R. H. Williams. J. Amer. Chem. Soc., 1906, **28**, 629—632.

It is shown that in pure dextrose solutions, when tested at constant volume with fixed amounts of phenylhydrazine hydrochloride and sodium acetate, the time required for the precipitation of the osazone varies with the quantity of dextrose present, and is nearly constant for any given dilution. Pure levulose solutions exhibit similar variations with concentration, but always yield a precipitate of osazone in about one-third the time required by the same amount of dextrose. From invert sugar solutions the osazone precipitates almost as rapidly as from levulose solutions of the same concentration. The presence of 1 per cent. of sucrose considerably shortens the time required for the precipitation of osazone from dilute (about 0·1 per cent.) dextrose solutions, but its effect is scarcely noticeable in levulose solutions. The precipitation is affected only slightly by the presence of raffinose. Maltose retards the precipitation of the osazone from dextrose solutions, and interferes less seriously in the case of levulose solutions; lactose influences the test in a similar manner to maltose, but to a greater degree. In every test, the same quantities of reagents were employed, *viz.*, 0·4 grm. of phenylhydrazine, 0·6 grm. of sodium acetate and 4 c.c. of water, the only variable factor being the amount of sugar or sugars present.

—W. P. S.

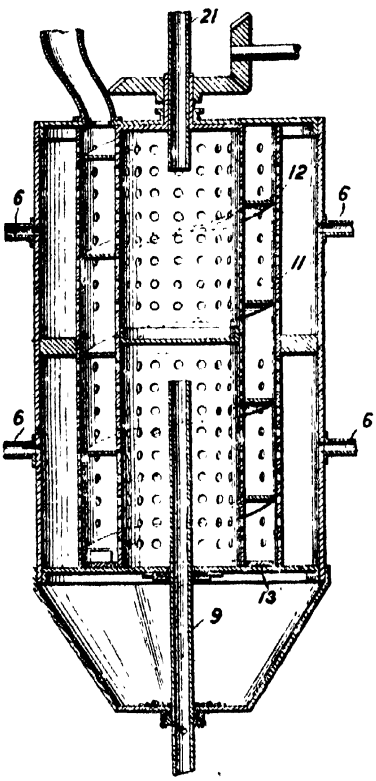
Rhodeitol. E. Votoček and J. Bulir. Z. f. Zuckerind. Böhmen, 1906, **33**, 332—339.

The methyl-pentose "rhodeose" is obtained from the glucoside convolvulin, or by the less expensive method of digesting jalap resin with warm baryta water and hydrolysing the extract by sulphuric acid. Rhodeose is reduced very slowly by sodium amalgam in acid liquids, but the reduction may be accelerated by maintaining an alkaline reaction not exceeding 0·5 per cent. of caustic soda. The product, rhodeitol, crystallises from alcohol in white plates with a silky lustre melting at 153·5° C. In aqueous solution it has a specific rotatory power of $[\alpha]_D = -1·45°$; or in a 10 per cent. borax solution, $[\alpha]_D = -4·6°$. Its solubility in 96 per cent. alcohol at 18·5° C. is 0·391 grm. per 100 c.c. When oxidised by bromine in presence of sodium carbonate or by nitric acid, rhodeitol yields rhodeoketose, no aldose sugar being formed. Rhodeitol is not oxidised by the sorbose bacterium (compare Bertrand, this J., 1905, 144); consequently, since this bacterium oxidises only those polyhydric alcohols of a certain stereochemical type, it is concluded that the configuration of rhodeose may be represented by the formula,

$$CHO.HCOH.OHCH.(CHOH)_2.CH_3$$

or its image. Rhodeose is the optical antipodes of fucose; when a mixture of the two sugars is reduced by sodium amalgam, an inactive alcohol, *r*-rhodeitol (= *r*-fucitol) is produced which melts at 168° C., and is therefore a true racemic compound.—J. F. B.

Trehalose; Determination of —— in trehala. P. Harang. J. Pharm. Chim., 1906, **23**, 471—473.



The biochemical method for the determination of trehalose by means of the ferment trehalase obtained from cultivations of *Aspergillus niger* (this J., 1906, 93) has been applied to the determination of that hexose in its original

source, trehala, the cocoons of *Larinus nidificans* (a species of beetle). Three authentic samples gave respectively 30·48, 27·16 and 23·48 per cent. of trehalose calculated on the dry material, a larger amount than that found by other investigators employing different methods. —J. O. B.

UNITED STATES PATENT.

Sugar machine. O. B. Barth, Loveland, Col. U.S. Pat. 810,250, Jan. 16, 1906.

THE apparatus consists of a cylindrical drum placed in a vertical position, and having an inner perforated cylindrical wall at a short distance from the outer solid wall. The annular jacket thus formed around the inner perforated cylinder is divided by a horizontal partition into upper and lower compartments. At the centre of the drum there is a revolving, hollow, perforated drum, 11 (see Fig.), which carries on its outer surface a spiral wing, 12, which scrapes the inner perforated wall of the containing drum. The sugar is fed into the annular space between the two perforated walls, and is carried downwards by the spiral wing. The central perforated drum is also divided horizontally into two compartments. Steam is fed into the upper compartment of this drum through the pipe, 21, and "blue water" is fed into the lower compartment through the pipe, 9. The outermost jacket of the drum is connected in both compartments with vacuum pipes, 6. The syrup is sucked into the jacketed space under the action of the vacuum, whilst the purified sugar is discharged at the bottom through a valve plate, 13.—J. F. B.

Hydrogen peroxide in malt analysis; The diastatic catalysis of ——. H. van Laer. J. Inst. Brewing, 1906, **12**, 313—338.

IN order to determine the catalytic power of malt, 3 grms. of the very finely ground sample are placed in an Erlenmeyer flask fitted with a lateral tube. The flask is clamped in an inclined position with the meal in the upper part of the bottom, and 25 c.c. of a solution containing 3·4 per cent. of hydrogen peroxide are introduced in such a manner that contact with the malt is avoided. The flask is then closed, the side-tube is connected with a Hempel burette, and the zero is adjusted. The time is noted, the contents of the flask are mixed by agitation for 10 seconds, and the volume of gas liberated in five minutes is noted. This volume is taken as a measure of the catalytic power of the malt. The hydrogen peroxide solution must be free from acid, and should be freshly prepared every day, being standardised by permanganate. The fineness of grinding and the temperature have a great influence on the results; the apparatus containing the reagents should be warmed to 20° C. in a water-bath before mixing. The catalytic activity of barley differs from that of malt in the fact that the volumes of oxygen evolved in the periods after the first five minutes, decrease far more rapidly in the case of malt than in that of barley, i.e., the malt catalase is more rapidly destroyed by the hydrogen peroxide than barley-catalase. The catalytic activity of barley increases during germination and decreases during the kilning of the malt. During kilning it undergoes two sudden falls, one during the drying of the green malt, in the first 24 hours, and another during the final curing. There is a continued production of catalase during the first 24 hours of kilning, but the net result is a loss during that stage. The catalytic activity of an infusion follows the same variations as that of the grain, except in the case of raw barley and kilned malt, which only yield a small proportion of their catalase to an infusion. Catalytic activity generally runs parallel to diastatic activity; certain divergencies, however, occur, some of which are referable to the fact that diastatic activity is determined in infusions and catalytic activity in the powdered grain; thus steeliness would lower the diastatic activity of an infusion owing to imperfect extraction of the diastase present. In very old malt the catalytic activity may have disappeared whilst a certain amount of diastatic activity is retained; the two are not identical. Catalytic activities, as determined in the above manner, may be divided into: Low, 1—38; medium, 39—72; and high, above 72. If the rotatory powers of the standard wort be classified as: Low, $[\alpha]_D$ below 115°, and high, $[\alpha]_D$ above 120°, the malts can be classified according to the indications of their catalytic activities and the rotatory powers. Generally, in normal cases, a high catalytic activity corresponds with a low rotatory power of the wort and with highly attenuated beers. When the results of both determinations are reconcilable, the conclusion as to the probable attenuation of the beer is confirmed. When the results are contradictory, it is best to trust to that for the catalytic activity, except in those cases where the rotatory power is too high in comparison with the catalytic activity. A high catalytic activity and a high specific rotatory power would indicate inferior modification of the malt, since the diastase would be present in large quantities, but not readily available in an ordinary infusion. A low catalytic activity occurring with a low specific rotatory power would indicate a large percentage of ready formed sugars or great friability of the malt.—J. F. B.

Yeasts; Top-fermentation and bottom-fermentation ——. *Studies on variation and heredity.* E. C. Hansen. Cent. Bakt. (Abth. 2). 1905, **15**; Woch. f. Brau. 1906, **28**, 220—221.

THE question of the change of type from bottom-fermentation to top-fermentation yeast and *vice-versa* has frequently been raised, and various isolated cases have been recorded, but without any satisfactory explanation. The author has made experiments with

a bottom-fermentation yeast, *Saccharomyces turbidans (S. ellipsoideus II.)*, by sowing a trace of yeast in a thin layer of beer wort and storing the cultures at a temperature of 0·5° C. for three to five months. At the end of that time sowings were made from the product, with the result that both the first and all the subsequent sub-cultures were found to have a pronounced top-fermentation character. This circumstance was explained in the following experiments. It was found on analysis that the original yeast could be split up into two portions, one consisting wholly of cells of bottom-fermentation type, and the other wholly of cells of top-fermentation type. When the cells of both types were treated separately at a low temperature, as described above, the bottom-fermentation cells did not multiply at 0·5° C., whereas the top-fermentation cells showed a considerable reproduction at that temperature. In sub-cultivations of the treated cells, it was found that the type had been preserved absolutely unchanged both in the treated cells themselves and in their descendants. Thus in the original experiment, the action of the low temperature had not really brought about a change of type, but had only caused a selective multiplication of the top-fermentation cells originally present. The wine yeast *S. Johannisberg II.*, generally regarded as a bottom-fermentation yeast, gave similar results. In the same way, on analysis, the top-fermentation yeast, *S. validus (S. Pastorianus III.)*, was found to contain 3 per cent. of cells with a bottom-fermentation character. These cells were separated and treated under various conditions favourable to top-fermentation for a period extending over two years, but neither the original cells nor their descendants could be induced to show any variation in type.—J. F. B.

Yeasts; The ash contents of certain ——. G. Heinzelmann. Jahrb. Ver. Spiritus-Fab. Deutsch., **6**, 21—22; Woch. f. Brau., 1906, **23**, 228.

THE author has obtained the following results from the analysis of the two varieties of distillery yeast, race II. and race XII., cultivated in wort from the same brewing:

	Race II.	Race XII.
	per cent.	per cent.
Water	76·7	73·7
Dry substance	23·3	26·3
Ash (on the dry substance)	9·90	8·13
Nitrogenous matter, as albumin (on the dry substance)	43·34	50·28
Non-nitrogenous matter (on the dry substance)	41·59	46·76
Composition of the ash—		
Phosphoric acid	54·41	52·72
Lime	0·95	0·80
Magnesia	4·86	4·79

Analyses are also given of a "Lufthefe" (yeast propagated by aëration) and of the yeast crop obtained from a vat fermented with it. The "Lufthefe" showed a very high albumin-content, 60·20 per cent. on the dry substance, but in spite of this its fermentative power, as indicated by the volume of carbon dioxide evolved under standard conditions, was very much lower than that of the skimmed yeast-crop which contained only 50·20 per cent. of albumin.—J. F. B.

Yeast; Relations of oxygen, and of movement of the nutrient solution to the increase and fermenting power of ——. L. Nathan and W. Fuchs. Z. ges. Brauw., 1906, **29**, 226—234, 243—252, 282—289, 299—304, 312—320.

THE authors give a critical account of previous publications dealing with the influence of oxygen on the growth of, and fermentation by, yeast. From the results of their own experiments, which are very comprehensive in character, the following conclusions are drawn: (1) As was found by Buchner, an abundant supply of oxygen exerts no appreciable favourable influence on the fermentative activity of yeast, but only stimulates the budding of the cells. (2) In a nutrient solution free from oxygen, a small amount of the latter endows the yeast with fresh fermentative power, but does not cause budding. (3) Regular motion of the liquid accelerates the fermentation by producing large surfaces of contact between the wort and the yeast, and causes the growth of an increased quantity of well-nourished, active yeast. (4) The amount of oxygen absorbed by a nutritive solution is far in excess of that necessary for the fermentation. (5) By diminishing the aëration or the oxygen content of the liquid, the increase in the amount of yeast produced by agitation of the solution can be annulled. The fermentation is then effected in a shorter time and without any considerable amount of extract being given up to the yeast. (6) The carbon dioxide produced during fermentation is capable of diminishing, to a slight extent, the budding power of the yeast, but it has no influence on the fermentative activity of the cells, provided the latter are sufficiently well supplied with food. (7) If the shaking be continued beyond a certain limited time, the fermentative and budding powers cease, and the yeast dies.

The paper is accompanied by a chronological list of publications on the subject.—T. H. P.

Alcoholic fermentation without cells; Action of peroxydase on ——. A. Bach. Ber., 1906, **39**, 1664—1668.

SUGAR solutions were submitted to the simultaneous action of zymase, peroxydase and hydrogen peroxide to ascertain whether under these conditions an oxidation of the carbohydrate or any of its degredation products takes place. It was found that the hydrogen peroxide is quantitatively converted into oxygen by the catalase in the yeast; further that active peroxydase markedly retards the alcoholic fermentation, whereas peroxydase solution which has been rendered inactive by boiling, as also hydrogen peroxide in the absence of peroxydase, are without any action on the fermentation. The presence of peroxydase and hydrogen peroxide has no effect on the acidity of the fermented liquid. The retarding action of peroxydase as measured by the production of carbon dioxide during fermentation varies with different preparations, but is always very marked; in some experiments the reduction in the amount of carbon dioxide produced is of the same order as the decrease in the power of the zymase to liberate oxygen from hydrogen peroxide, but when more active peroxydase preparations are used, the yeast zymase is much more affected than the catalase. Bearing in mind that yeast is one of the few organisms which do not contain a peroxydase, the retarding action of peroxydase on the phenomenon of alcoholic fermentation without cells is of particular interest, and it would appear that the splitting up of sugar into carbon dioxide and alcohol and the presence of a peroxydase, are incompatible.—E. F. A.

Alcoholic fermentation without cells; Fate of yeast catalase in ——. A. Bach. Ber., 1906, **39**, 1669—1670.

PARALLEL experiments were carried out in which zymase, prepared by the acetone method, was allowed either to ferment a sugar solution or to undergo autolysis, and the activity of the catalase remaining in each solution was tested from time to time. It was found that the amount slowly diminished as autolysis proceeded, whilst during the sugar fermentation the process of decomposition was much more rapid. Dilution of the zymase increased the rate of destruction of the catalase in either case. No definite relationship could be established between the amount of catalase in the yeast and its fermentative activity.—E. F. A.

Catalase; Influence of peroxydase on the action of ——. A. Bach. Ber., 1906, **39**, 1670—1672.

ALTHOUGH in sugar solutions, during fermentation with zymase, the activity of yeast catalase falls off more rapidly in presence of active peroxydase than in that of the boiled enzyme, it is shown that at 30° C. vegetable (yeast) catalase is not harmed by prolonged contact with active peroxydase. In the case, however, of animal catalase from ox liver an increase in the activity was at first observed on adding active peroxydase, though after 48 hours' contact there was no difference in the activity of the catalase preparations to which fresh and boiled peroxydase solutions had been added respectively. No explanation is at present offered for the difference observed in the case of sugar solutions.—E. F. A.

Fermentation industries; The present position of the British ——. J. L. Baker. Pharm. J., 1906, 76, 439—442; 465—467; 496—498.

THE author describes the fermentation processes of the beer, spirit and cider industries of this country, discussing more particularly the question of pure yeast cultivated from a single cell in relation to these industries. The processes of isolating single cells from mixtures of yeast and of cultivating the isolated colonies in the Hansen-Kühle aseptic propagating apparatus are described in detail. This process has been successfully carried out in practical brewing by the author for a considerable time. He finds that the stock of single-cell yeast tends to become contaminated in brewery work after three to five successive runs. This difficulty is surmounted by taking regularly fresh cultures from the Hansen apparatus, propagating these cultures in a small tun of 250 galls. capacity and fortifying the slightly contaminated stock of pitching yeast with the contents of this tun. In this way the predominance of the pure culture yeast is assured. The pure yeast system has been applied chiefly for the fermentation of mild ale worts. The obstacle which has stood in the way of the general adoption of pure-culture yeast for the preparation of top-fermentation beers in this country has been the difficulty of obtaining natural conditioning by secondary fermentation. This, however, does not apply to running ales destined for quick consumption. In the author's opinion there is no sharply-defined line between primary and secondary fermentation requiring the activity of two different types of yeast; the process is more probably a continuous one. With single-cell yeast, after the violent primary fermentation ends, the residual yeast becomes for the most part quiescent. During the resting period the hydrolytic enzymes in the yeast cell undergo some modification and become active, since it has been observed that the fermentative energy, as measured by the evolution of carbon dioxide and the loss of gravity, becomes once more apparent. This recurrence of activity is more marked in some races of yeast than in others.

In the whisky industry, practically nothing has been done in the way of applying pure single-cell yeast for the fermentation of the worts, although the system is fully established in Continental distilleries. In view of the intimate dependence of the quality of the spirit on the volatile by-products of fermentation, attention to the selection of the most suitable races of yeast for the production of the more valuable amongst these by-products ought to yield profitable results. At present most pot-still distillers obtain their yeast from a neighbouring brewery.

Lastly, the author refers to the successful use on the Continent of pure cultures of fine-vintage wine yeasts for the fermentation of cider musts.—J. F. B.

Hops; Extraction of —— by solutions of various mineral salts. J. Heron. J. Inst. Brewing, 1906, 12, 300—301.

IN these experiments 10 grms. of hops were digested at the boiling temperature with 900 c.c. of solutions of the various salts containing 21 grains per gallon for one hour. The liquids were then made up to 1005 c.c. and filtered, and the extracts were examined. The following results are recorded:—

Salt.	Extract per cent.	Colour in 4 in. cell total units	Analysis of colour.		
			Red.	Yellow	Flavour.
Sodium chloride ..	18	7·2	1·2	6·0	Pleasant
Calcium chloride ..	17	5·7	1·2	4·5	,,
Sodium sulphate ..	16	6·8	1·3	5·5	Rank
Potassium sulphate	16	—	—	—	Harsh
Magnesium sulphate	16	6·2	1·2	5·0	Pleasant
Calcium sulphate..	17	6·5	1·5	5·0	,,
Sodium carbonate	19	10·9	1·9	9·0	Nauseous
Potassium carbonate	18	11·6	2·6	9·0	,,
Calcium carbonate	18	11·2	2·8	8·4	,,
Distilled water ...	20	4·7	1·1	3·6	Pleasant

—J. F. B.

Tintometer; The use of Lovibond's ——. J. L. Baker and H. F. E. Hulton. J. Inst. Brewing, 1906, 12, 302—304.

THE authors have observed that when Lovibond's tintometer is employed for the determination of the colour of worts, the results are liable to vary according to the position of the instrument and the manner in which the light falls upon it. When the readings are taken with the opal glass reflector directly facing a window (north light), the results are very much lower than when the illumination is from behind or from the side. The readings with a back or side illumination correspond well with those taken with a front illumination when the top light is cut off by covering over the space between the cell and the reflector. The above discrepancies, so noticeable in the case of malt worts, are not observed when the liquid in the cell is a mild or pale ale. The authors have observed that, in the case of malt worts with a front light, the readings are about half a degree higher when the malt extract is on the left-hand side of the standard field than when it is on the right-hand side. Caramels and black malt extracts are very difficult to match with the "52" series glasses. When a liquid cannot be matched with a single glass, it is desirable that one of the compound glasses should be as near as possible to the intensity required.—J. F. B.

Beer; Nitrogenous substances in ——. O. Miskovsky. Z. ges. Brauw., 1906, 29, 309—312.

THE author describes the methods he adopts to determine the various nitrogen compounds in beer and gives the following results obtained:—

	1 litre of beer contains.	100 grms. of dry matter of beer contain.
	grms.	grms.
Total nitrogen	0·308	0·833
Albuminoid nitrogen (according to Rümpler)	0·188	0·509
Albuminoid nitrogen (according to Stutzer)	0·112	0·303
Ammonia-nitrogen	0·010	0·027
Nitrogen coagulated by magnesia	0·045	0·122
Amide-nitrogen	0·015	0·041
Amino-acid nitrogen (according to Stanĕk)	0·036	0·097
Xanthine-nitrogen	0·013	0·035
Choline-nitrogen	0·009	0·024

—T. H. P.

Beers; Darkening of pale ——. *C.* Bleisch and K. Runck. Z. ges. Brauw., 1906, 29, 277—282.

ONE of the fundamental factors to which the darkening of pale beers is due is the presence of a large amount of calcium carbonate in the brewing water. Calcium sulphate, on the other hand, favours the formation of a pleasant greenish-yellow colour in the beer. Alkali carbonates also cause darkening, but these compounds seldom occur in brewing waters. The darkening of pale beers may hence be obviated by the use of gypsum, by thoroughly boiling the brewing and sparge liquors, and also by employing a thin mash. Badly coloured and, especially, old hops should be avoided. The darkening is strongly aided by aërating the wort and maintaining it at a high temperature, particularly in presence of calcium carbonate. Long standing of the wort and pumping, especially with centrifugal or capsule pumps, also increase the colour owing to the aëration they effect. The employment of deep coppers is also detrimental. Iron coppers

have, in general, no influence on the colour of the beer, nor, in all probability, have copper ones, and no difference in this respect can be observed between fire and steam heating.—T. H. P.

Brandy fermented by beer-yeast and cask-lees; Improvement of the flavour of ——. G. Heinzelmann. Jahrb. ver. Spirit. Fabr. Deutsch., 6, 22; Woch. f. Brau., 1906, 23, 227.

THE brandy obtained had an alcoholic strength of 47 per cent., a turbid appearance and a sharp, irritating flavour, and was not suitable for drinking purposes. Filtration through charcoal or distillation from alkali did not bring about the desired improvement in quality. On the other hand, when the brandy was treated with oxidising agents, such as hydrogen peroxide and subsequently distilled with alkali, the flavour was much improved.—J. F. B.

Cloudy beer; Bacteriological investigation of ——. M. Ogawa. Eisec Saikingaku Jiho, 1904, 1, No. 2; Z. ges. Brauw., 1906, 29, 308.

THE author has examined 27 bottles of beer of six different kinds on the appearance of turbidity. Along with yeast, he found generally very common bacteria, such as the potato bacillus, hay bacillus, brown potato bacillus, &c. In only 7·4 per cent. of the beers investigated was a thread fungus found as the cause of the turbidity.—T. H. P

Distillery washes; Analysis of fermented ——. H. Hanow. Z. Spiritusind., 1906, 29, 180—181.

THE analysis of a fermented wash should include a microscopic examination, and determinations of the attenuation, acidity, presence or absence of diastase, alcoholic contents and the presence of fermentable carbohydrates (see also this J., 1904, 263). The author tabulates the results of the analysis of 18 samples of fermented washes (potato) and discusses their bearing as regards the detection of the causes of defects. If the density of the filtered wash exceeds 1° Balling, the attenuation may be regarded as poor. The process of examination consists in removing the alcohol by evaporation, neutralising any excessive acidity, adding diastase if the original wash was defective in this respect, and fermenting under favourable conditions with pure yeast. Poor attenuations due to bad fermentations will be accompanied by high acidities (above 0·8°); the excessive acidity may also cause a destruction of the diastase. Diastase may be absent even from well attenuated washes, but it is generally present in such cases. Under the conditions described above, even well attenuated washes will yield a further quantity of about 0·3 per cent. of alcohol. If a larger quantity be obtained, the original attenuation will have been poor and the fault will be traced either to bad fermentation, indicated by high acidity, or to insufficiency of diastase in the original wash. If a further yield of alcohol cannot be obtained, and if the original attenuation was poor, the cause may be attributed to the presence of unfermentable matters in the potatoes or to the formation of such substances by over-steaming.

Vinasses should not contain more than 0·1 per cent. of alcohol; their acidity ranges from 0·5° to 0·9°, and their solid extract from 5·0 to 5·6 per cent. A high acidity indicates souring of the vinasses after cooling, owing to bacterial action. Sour or imperfectly fermented or distilled vinasses cause diseases in cattle. It is recommended that vinasses for fodder should be boiled under pressure after distillation.—J. F. B.

Sugar-beet; The enzymes of the ——. J. Stoklasa. XVI., page 549.

Carbon dioxide; Diffusion of —— through caoutchouc. Grunmach. XIIIC., page 547.

ENGLISH PATENT.

Lactic acid; Method for manufacturing —— for technical purposes. E. A. Mislin, Prague, and L. Lewin, Vienna. Eng. Pat. 10,436, May 18, 1905.

FRENCH PATENT.

Amylaceous materials; Treatment and fermentation of —— by mucedinae and other ferments. E. Deleurance. Fr. Pat. 361,030, August 10, 1905.

THE grain is sterilised and steeped by heating with water and a little acid for an hour at the boiling temperature, agitation being effected by the injection of filtered air. The mixture is then boiled under a pressure of 3—4 atmospheres in a convertor for a short time until the starch is rendered soluble. The mash is then pumped through a sterilised refrigerator, and when it is sufficiently cool, it passes into the saccharifying vessel where it is treated in the usual aseptic manner with the mucedinae ferment. The saccharifying vessel is capable of holding several charges from the convertor which are admitted in succession. This vessel only requires sterilising when it is first started; it is never emptied completely, the residue from one charge serving to inoculate the next. The development of the yeast is effected in a similar manner in another vessel under aseptic conditions, and when violent fermentation has begun, the mash is discharged into wooden tuns where fermentation is completed under ordinary conditions.
—J. F. B.

GERMAN PATENT.

Grains, e.g., of maize, which have not been subjected to a preliminary treatment; Process for the rapid steaming of —— for use in the spirit and pressed yeast industries. H. A. Hübner. Ger. Pat. 166,628, May 19, 1904.

THE grains are charged as rapidly as possible into a steamer containing boiling water, and provided with two steam-pipes; the steamer is then hermetically closed, and a strong current of steam is introduced through the lower steam-pipe in order to raise the pressure directly to 2—3 atmospheres, after which the steaming is completed by gradually further raising the pressure to four atmospheres. According to another claim, steam under pressure is introduced at first, and then, after some time, the upper steam-pipe is closed, and the steam which has collected in the upper part of the steamer is allowed to escape, the lower steam-pipe being kept open throughout the process.

(A.)—FOODS.

Gliadin; Optical rotation and density of alcoholic solutions of ——. W. E. Mathewson. J. Amer. Chem. Soc., 1906, 28, 624—628.

THE results given show that the specific rotation of gliadin in 70 per cent. to 75 per cent. alcohol is practically independent of the gliadin concentration, but with 70 per cent. to 80 per cent. alcohol it decreases with the increase of the alcohol concentration. Increase of temperature between the limits 20°—45° C. produces a slight increase in the specific rotation; a sample of gliadin had a specific lævo-rotation at 20° C. of 91·3° which at 45° C. rose to 93·6°. The change in specific gravity of gliadin solutions for such differences as would be met with in flour analysis is not large, and determinations of gliadin in flour from the density of the alcoholic extract, as recommended by Fleurent (this J., 1901, 941), cannot be made with any approach to accuracy.—W. P. S.

[Milk] Separators; Centrifugal liquid ——. G. de Laval, and E. E. F. Fagerström, Stockholm, Sweden. Eng. Pat. 5859, March 10, 1906.

The claim is for the introduction of a horizontal plate, *e*, disposed below the conical division plate, *b*, but not extending as far as the latter, for the purpose of preventing the milk which is fed down the central pipe, *a*, and flows out of the openings, *d*, under the cone *b*, into the drum *c*, from mixing with the cream which tends to collect under the plate, *e*. Tubes, *f*, passing through both the plates, *e*, and *b*, are provided to allow the cream to pass from beneath the plate *e*, to the upper part of the drum *c*, where it flows away through the cream outlet.—W. H. C.

French Patents.

Vegetables; Preservation of ——. L. Fontaine. Fr. Pat. 360,806, March 15, 1905.

The vegetables, such as peas, beans, &c., are immersed for from five to ten minutes in boiling water containing from ½ to 3 thousandths of their weight of sodium aluminate. The latter forms a stable green lake with the chlorophyll contained in the vegetables.—W. P. S.

Milk, cream, and analogous substances; Process of treating ——. A. T. Pfeiff. Fr. Pat. 360,654, Dec. 19, 1905.

The fat of milk, it is stated, consists partly of large, soft globules and partly of smaller, waxy globules, the latter tending to reduce the quality of the butter obtained from the milk or cream. In order to soften the waxy globules and remove dissolved gases from the milk or cream, with a view to obtaining an improved quality of butter, the liquid is alternately heated to near its boiling point and then cooled, while kept in continuous movement, in a current of purified air. The liquid is preferably treated in thin layers, to expedite the heating and cooling, and thus obviate deterioration in the flavour owing to prolonged treatment.—H. B.

Milk; Process for the preservation of ——, for a short time. P. Bretsau. Fr. Pat. 360,679, Dec. 19, 1905.

The fresh milk is placed in suitable receptacles and a slow current of an inert gas, such as carbon dioxide, passed through it. The supply of gas is then cut off, and the milk subjected to as low a pressure as possible. After repeating these operations a second time, the milk is heated to a temperature of about 40° C., under reduced pressure. Carbon dioxide is then again admitted, the receptacles are hermetically closed and cooled. Milk preserved in this manner will, it is claimed, remain fresh for about 15 days.—W. P. S.

Milk powder and milk products. G. A. Kammermann. Fr. Pat. 360,764, Dec. 21, 1905.

Milk, either alone or mixed with cocoa, sugar, coffee, &c., is evaporated at a temperature below 100° C. The condensed product obtained is then further dried on hot rollers heated to a temperature below 100° C., the rollers being so worked that when they have made a half revolution, the film of dry milk is removed by a scraper.—W.P.S.

Wheat; Process for cleaning ——. W. R. Reid. Fr. Pat. 360,659, Dec. 19, 1905.

The grains are intimately mixed with finely powdered slaked lime or other substance before being subjected to the action of a winnowing machine, the object being to destroy sticky substances which cause dirt, &c., to adhere tenaciously to the grains. About 1 part by volume of lime to 400 parts of grain is a suitable quantity to employ. —W. P. S.

Eggs and egg-containing substances; Process of drying ——. J. R. Hatmaker. Fr. Pat. 361,117, Dec. 26, 1905. Under Int. Conv., Jan. 2, 1905.

See Eng. Pat. 28 of 1905; this J., 1905, 1319.—T.F.B.

Albuminoid rich in nitrogen and phosphorus; Extraction of an ——, from the marc of grapes. G. E. Jacquemin. Fr. Pat. 361,125, Dec. 28, 1905.

The waste substance, such as the marc, stones, &c., of grapes, is ground, dried, freed from oil, and then macerated with soft water for some days. The liquid portion is decanted, heated to a temperature of 50° C., and allowed to settle. The precipitate formed is collected and dried under reduced pressure. The residue left after the maceration is pressed, mixed with its own weight of sand and 2 per cent. of its weight of sodium carbonate, and then treated with boiling water acidulated with hydrochloric acid. Sufficient acid must be used to make the solution feebly acid in reaction. The solution is concentrated, treated with lime water and sodium acetate until practically neutral, and the precipitate which forms collected, dissolved in water and purified by recrystallisation. The precipitate is finally dissolved in water and added to the filtrate from the first precipitate. The resulting turbid liquid is dialysed and the residue mixed with the first precipitate.—W. P. S.

(*B.*)—SANITATION; WATER PURIFICATION.

Air which extinguishes flame; Analysis of a sample of ——. B. Blount. Analyst, 1906, 31, 144—145.

The air in a large cold storage was found to be incapable of supporting combustion as it contained only 17·5 per cent. of oxygen by volume. At one part of the room was the shaft of a disused well up which passed a strong current of air, evidently coming from some neighbouring tunnels where compressed air was in use. The escaping air from these tunnels passed through ground containing pyrites, which removed some oxygen, before finding a vent up the well-shaft. Ordinary air when kept in contact with the mud obtained from the bottom of the shaft was completely deprived of its oxygen.—W. P. S.

ENGLISH PATENT.

Smoke issuing from smoke funnels, chimneys and the like; Improved process for laying ——. P. Kestner, Lille, France. Eng. Pat. 9549, May 5, 1905.

WATER or steam according to the temperature, is injected into the smoke gases which are then passed through a mixing fan. As the smoke cools, the steam condenses on the solid particles of soot, &c., and causes them to become heavier, so that they are said to be deposited almost immediately after leaving the funnel.—W. H. C.

UNITED STATES PATENTS.

Air for respiration purposes; Apparatus for re-oxygenating exhaled ——. M. Bamberger, F. Böck and F. Wanz, Vienna. U.S. Pat. 819,704, May 1, 1906.

SEE Eng. Pat. 9185 of 1905; this J., 1905, 1027.—T. F. B.

Sewage or the like; Screen for ——. F. Brunotte, Hamburg, Germany. U.S. Pat. 819,720, May 8, 1906.

SEE Eng. Pat. 11,231 of 1905; this J., 1905, 1250.—T. F. B.

FRENCH PATENT.

Water; Process and apparatus for introducing reagents for the purification of ——. J. Overhoff. Fr. Pat. 360,397, Feb. 22, 1905.

THE water to be purified flows from a reservoir, placed some height above the other parts of the apparatus, through a pipe into the lower part of a vessel containing milk of lime. This vessel is closed and has the shape of an inverted cone. The water is thus saturated with calcium hydroxide, and arrives at the top or wider part of the vessel as a clear solution, which is conducted downwards through a pipe to the bottom of a cylindrical vessel, where it receives the addition of dilute sodium carbonate solution. The latter is contained in a separate narrow cylinder, from which it is forced into the main cylinder by the pressure of water derived from the reservoir. When required, the milk of lime may be renewed in the conical vessel by cutting off the water supply and opening a tap at the bottom of the vessel. Part of the contents flow out, reducing the pressure in the vessel. The tap is then closed and a fresh supply of milk of lime drawn in at the top of the vessel through a tapped pipe from a lime tank. Similar means are provided for re-filling the sodium carbonate cylinder. The supply of sodium carbonate solution is regulated by a tap on the pipe conveying it to the main cylinder. The treated and settled water passes from the top of the main cylinder into a collecting tank.—W. P. S.

(*C.*)—DISINFECTANTS.

Disinfecting action; Relations between chemical constitution and ——. H. Bechhold and P. Ehrlich. Z. physiol. Chem., 1906, **47**, 173—199. Chem. Centr., 1906, **1**, 1444—1445.

THE experiments were confined to phenol and its derivatives and allied substances, and the disinfecting action was studied chiefly on diphtheria bacilli, but also on other pathogenic bacteria (B. coli, pyocyanaeus, typhi, Streptococci and Staphylococci). It was found that the introduction of halogens (chlorine and bromine) into the phenol molecule, increases the disinfecting effect of the latter; 1 mol. of monobromophenol has the same effect on diphtheria bacilli as 500 mols. of phenol. The disinfecting power is also increased by the introduction of alkyl groups into phenol or its halogen derivatives, and also by the union of two phenol residues, either directly or by a connecting group such as CH_2, CHOH, $CHOCH_3$, $CHOC_2H_5$. The union of two phenol residues by a CO or SO_2 group, or the introduction of a COOH group into the phenol molecule has an injurious effect on the disinfecting power. The following new disinfectants are described:—Tetrabromo-*o*-cresol prevents the development of diphtheria bacilli at a dilution of 1:200,000, and kills the organisms in less than two minutes when used as a 1 per cent. solution. It has little toxic effect at the dilutions mentioned. Tetrachloro- and tetrabromo-*o*-diphenol also destroy diphtheria bacilli in less than two minutes in 1 per cent. solution, and prevent their development at a dilution of 1:640,000. Hexabromodihydroxydiphenylcarbinol is practically non-poisonous; in 1 per cent. solution it destroys diphtheria bacilli in from two to more than 10 minutes, and prevents development of the bacilli at a dilution of 1:200,000. It has little effect on water bacteria.—A. S.

Disinfectants; Influence of organic matter on the efficacy of certain ——. M. W. Blyth. Analyst, 1906, **31**, 150—155.

THE experiments here recorded have particular regard to the influence which even small quantities of organic matter have on the comparative germicidal values of disinfectants of the phenol class. The disinfectants dealt with are phenol, cresols, "Izal," "Cyllin," resorcinol and pyrogallol. From the results given, it is seen that the higher phenols suffer a great loss of efficacy when mixed with fat, albumin or fæces and urine, but that the influence is much less in the case of phenol itself. The germicidal value of a disinfectant, acting on a "naked" organism gives little, if any, indication of its value in the presence of organic matter. In some experiments with worms of equal weight, it was found that the time taken to kill them by means of 5 per cent. solutions was:—Phenol, half a minute; cresols (ortho, meta and para), three-quarters of a minute; resorcinol, 3 minutes; pyrogallol, 5 minutes; "Izal" and "Cyllin" over 10 minutes. The poisonous nature of phenol, resorcinol and pyrogallol seems to be decreased as hydroxyl groups are introduced, and is directly proportional to the germicidal value. Taking phenol, cresols, "Izal" and "Cyllin," the germicidal value appears to be in inverse proportion to the poisonous nature; but phenol and cresols, which lose but little germicidal value when mixed with milk, are highly toxic, whilst "Izal" and "Cyllin" which lose about 80 per cent. of their germicidal value when mixed with milk, are but little toxic. The supposition that a poisonous albumin-phenol is formed, the act of union killing the organism, is supported by the fact that, although resorcinol gives a copious precipitate with albumin, it suffers but little loss of germicidal value. It appears impossible in the phenol class to combine a low toxic value with a high germicidal value in the presence of much organic matter.—W. P. S.

FRENCH PATENT.

Disinfection, &c.; Process and apparatus for ——, *and for the production of formaldehyde [from burnt sugar].* E. Rouquier. Fr. Pat. 360,476, Feb. 24, 1905.

SUGAR or other carbohydrate is heated in a metallic dish above which is placed a dome-shaped cover containing several horizontal sheets of wide-meshed copper gauze, fitted one above the other to a central rod. The gases produced by the combustion of the sugar pass through the metallic sheets, which have a catalytic action, and are then allowed to enter the room, &c., to be disinfected, or are passed through water to form an antiseptic solution. Formaldehyde may be separated from the latter. Several forms of apparatus constructed on the above principle are described.—W. P. S.

XIX.—PAPER, PASTEBOARD, Etc.

(*Continued from page 494.*)

Paper and pulp mill effluents. J. H. Vogel. Papier-Zeit., 1906, **31**, 1278—1280, 1314—1316 and 1355.

THE author expresses the opinion that the effluents from paper mills may as a rule be quite suitably discharged into a river of moderate size, provided the suspended matters be previously removed. The organic matters dissolved in these effluents are derived from the washing of rags or straw and similar pulps; they are considerably diluted by the purer waters from the paper machine and

are favourably influenced from a hygienic point of view by the residues of bleaching materials they contain. The effluents are not highly putrescible, but the discharge of any considerable quantity of fibrous matter into the streams is injurious to fishes and vegetation. The effluents from sulphite wood-pulp mills, on the other hand, are very objectionable, and no satisfactory process exists for their purification. These liquors contain, in addition to the sulphur derivatives, considerable quantities of sugars which afford nutriment for the growth of a fungus, *Sphærotilus natans*, in the streams. Hofer has shown that it is the fermentable hexose sugars, principally, which give rise to this growth. Numerous attempts have been made to treat the liquors by the same process as is employed for the bacterial purification of sewage, but the sulphur compounds have such an inhibitive action on the bacteria that no purification is effected in the beds. The author thinks, however, that if the liquors were first treated for the precipitation of sulphites, and were then subjected to putrefaction in a septic tank with the addition of sewage, something might be effected by this process. Some mills dilute their liquors and run the effluent continuously day and night into the stream; but Hofer considers that less harm is done by discharging the whole of the liquors at once, intermittently, provided the stream is a large one, since the fungus growths are thereby nourished for a shorter time. The so-called continuous settling arrangements do not remove the suspended matters so efficiently as sedimentation in tanks; in these, after 12—15 hours, the liquors only contain 10—12 mgrms. of suspended matter per litre. In soda-pulp mills, only the more dilute washings, containing 10 per cent. of the total wastes, have to be discharged. In small streams these liquors give rise to the accumulation of algæ. They should, however, be quite amenable to treatment on the bacterial system after a preliminary putrefaction in a septic tank, which would also serve for the removal of the fibrous matters by sedimentation.—J. F. B.

United States Patent.

Strawboard; Process of making ——. P. Prins, Minneapolis, Minn. U.S. Pat. 819,595, May 1, 1906.

Straw is chopped into short lengths and placed in a closed boiler with quicklime in the proportion of 0·06 lb. per lb. of straw. Steam under a pressure of about five atmospheres is then introduced and the mixture of straw and lime is kept in agitation for about 3½ hours. The pulp is then ground up into a homogeneous mass and is beaten, filtered and made into sheets in the usual way.—J. F. B.

French Patents.

Sulphite liquors; Preparation of strong —— and apparatus therefor. G. Türk. Fr. Pat. 361,071, Dec. 9, 1905. VII., page 537.

Paper pulp; Process and apparatus for preparing ——. P. Couper. Fr. Pat. 361,005, Dec. 29, 1905. Under Int. Conv., Feb. 10, 1905.

See Eng. Pat. 2774 of 1905; this J., 1905, 1251.—T. F. B.

Silk; Process for the manufacture of artificial ——. P. Germain. Fr. Pat. 360,395, Feb. 22, 1905. V., page 532.

Celluloid; Non-inflammable ——. H. Lagneau, E J. Nebel and M. E. Vignes. Fr. Pat. 360,912, March 18, 1905.

Four parts of a supersaturated solution of magnesium sulphate are treated with 2·5 parts of amyl acetate, containing 1 part of camphor, and 1 part of nitrocellulose is added. The nitrocellulose dissolves and the solution floats on the top of the aqueous layer. The whole is then thoroughly incorporated together and the celluloid is produced in sheets under the action of heated rolls. A large number of other salts, capable of resisting heat and extremely soluble in water, can be employed instead of the magnesium sulphate. The celluloid obtained is stated to be transparent and non-inflammable.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 496.)

Cocaine hydrochloride; Decomposition of —— on keeping. P. Breteau. J. Pharm. Chim., 1906, **23**, 474—476.

A specimen of cocaine hydrochloride 15 years old was found to have decomposed into methyl benzoate, free benzoic acid, and ecgonine hydrochloride. This decomposition is attributed to the presence of a trace of water in the lamellar form of crystals characterising the salt in the earlier years of its commercial production. The granular crystalline hydrochloride of the present day is perfectly anhydrous; but it should be carefully preserved from contact with any trace of moisture to obviate decomposition.—J. O. B.

Aconite root; Variability in potency of ——. Chevalier and Bardet. Bull. gén. de Therap. (Paris), 1905, **150**, 713. Pharm. J., 1906, **76**, 471.

The amount of total alkaloids in aconite root is generally from 0·2 to 0·5 per cent., but Chevalier found in a sample from North America, 0·378 per cent. of crystalline aconitine and 0·583 per cent. of an amorphous base having the m. pt. 204·5° C. and the optical rotation of japaconitine. An extract made from this root by the method of the Codex would contain 50 mgrms. of alkaloids in 1 grm. instead of the usual 25 mgrms. The morphological characters of the root agreed in every particular with those given in the official (Codex) description. Bardet states that aconite root from the Zinal Valley is much more toxic than that from the Vosges.—A. S.

Lichen substances. W. Zopf. Annalen, 1906, **346**, 82—127.

The author gives descriptions of the principal constituents of the following varieties of lichens. *Rhizoplaca chrysoleuca* (Sm.) Zopf.; *Rhizoplaca opaca* (Ach.) Zopf.; *Lecanora sulphurea* (Hoffm.) Ach.; *Biatora Lightfootii* (Sm.) *f. commutata* (Ach.); *Biatora granulosa* (Ehrh.) Mass.; *Blastenia Jungermanniae* (Vahl); *Cladina rangiferina* (L.) Wainio; *Cladina destricta* (Nyl.); *Cladina silvatica* (L.) Hoffm.; *Cladina silvatica* (L.) Hoffm. var. *spumosa* Flörke; *Haematomma leiphaemum* (Ach.); *Haematomma porphyrium* (Pers.); *Haematomma coccineum* (Dicks); *Parmelia Mougeotii* Schaerer; *Lepraria candelaris* Schaer. A note on rhizocarpinic acid is given, and a full description of diploschistesic acid.—F. Shdn.

Terpenes and essential oils, 78th communication. Pinene series. O. Wallach. Annalen, 1906, **346**, 220—247.

Pinocarveol, $C_{10}H_{15}OH$, is obtained by treating pinylamine with sodium nitrite and excess of acetic acid. It is a colourless liquid, boiling at 100°—102° C. at 12 mm.; sp. gr. 0·980 at 18° C.; $n_D^{18°} = 1·4988$; M, 45·52. This value of M (the molecular refraction) agrees with that calculated for an alcohol with one ethylene linkiny. On oxidation with chromic acid, pinocarveol yields a certain amount of pinocarvone, $C_{10}H_{14}O$, which is not the ketone corresponding to nitrosopinene. When purified through the semicarbazide (m. pt. 204° C.), pinocarvone boils at 95° C. at 12 mm., and has the sp. gr. 0·984 at 20° C.; $n_D^{20°} = 1·5050$; and M, 45·21. Both pinocarveol and pinocarvone give pinic acid on oxidation with permanganate. In the transformation of pinylamine into pinocarveol, the double bond moves from the ring to the side-chain. There is every reason to believe that an optically active pinocarveol is present in the essential oil of *Eucalyptus globulus* (this J., 1905, 1029). The ketone corresponding to nitrosopinene is carvopinone, $C_{10}H_{14}O$, which is obtained in small quantities by treating nitrosopinene with oxalic acid. Carvopinone boils at 94°—96° C. at 12 mm. and from it small glistening prisms of a semicarbazone are obtained, which do not melt below 300° C. Reduction with sodium and alcohol

ives pinocamphone $C_{10}H_{16}O$. When treated with ydroxylamine, carvopinone gives a substance strongly esembling nitrosopinene. If nitrosopinene be reduced rith zinc and glacial acetic acid, pinylamine and a aturated ketone, pinocamphone are produced. Pino-amphone boils at 87° C. at 12 mm. and gives a semi-arbazone, m. pt. 208° C., and dibrompinocamphone, $_{10}H_{14}Br_2O$, m. pt. 116°—119° C. It is very stable owards acids. Chromic acid oxidation produces *a*-pinonic cid, and an isomeride of camphoric acid, m. pt. 186°—87° C. The constants of pinylamine have been again etermined; sp. gr., 0·9400 at 20° C., 0·9440 at 15° C.; $^{20°}_{D} = 1·5036$; $n^{15°}_{D} = 1·5062$; M, 47·53, 47·54. The alue of M corresponds to one ethylene bond. Oxidation f pinylamine by permanganate in the cold produces arvopinone and an acid $C_9H_{14}O_3$. If pinene is treated rith nitrous acid and reduced with zinc and acetic acid, minoterebenthene, $C_{10}H_{17}N$, is produced. The base from -pinene has the sp. gr., 0·9325 at 19° C.; $n^{19°}_{D} = 1·4960$; $_D = -1°37'$. The base from *l*-pinene has the sp. gr. 0·9320 t 20° C.; $n^{20°}_{D} = 1·4957$; and $\alpha_D = -1°55'$. On oxida-ion with chromic acid, cuminic aldehyde and cuminic cid are produced. It appears that the amino-group is ttached to the side chain in aminoterebenthene and that he base is the derivative of a methene-terpene, probably iopinene.—F. Shdn.

Terpenes and essential oils, 79th communication. Cyclo-hexanone series. O. Wallach. Annalen, 1906, **346**, 249—265.

This paper includes the following. Comparative beha-viour of 1.2-, 1.3-, and 1.4-cyclomethylhexanones. Con-stitution of the isoximes of 1.3-cyclomethylhexanone. soximes from trimethylcyclohexanone. Isomerism mongst the bases derivable from 1.3-methylcyclohexanone. —F. Shdn.

Terpenes and essential oils, 80th communication. Iso-carvoxime, carvoline and isomerism of oximes. O. Wallach. Annalen, 1906, **346**, 266—285.

This paper deals with isocarvoxime and its bromine ddition products, also its reduction to carvoline. If the mino group in carvoline be replaced by chlorine and the esulting compound oxidised, *p*-acetyl-chloro-toluene is roduced.—F. Shdn.

Eucalyptus staigeriana, F. v. M., and its essential oil; The lemon-scented ironbark ——. R. T. Baker and H. G. Smith. Pharm. J., 1906, **76**, 571—572.

Eucalyptus staigeriana is a small tree found in Queens-and, the leaves of which yield, on distillation, 2·5 per ent. of a mobile oil having a light lemon-yellow colour, nd a very aromatic odour, quite different from that f ordinary eucalyptus oil. The oil has the sp. gr. 0·8708 t 16° C., optical rotation $[\alpha]_D = -43·1°$; refractive ndex at 16° C., 1·4871; it is not soluble in six volumes f 80 per cent. alcohol by weight, and a slight turbidity emains even with eight volumes. The principal con-tituents are as follows: *l*-limonene, 60·00; geraniol, 2·72; geranyl acetate, 8·32; and citral, 16·00 per cent. he oil is interesting as being the first eucalyptus oil n which *l*-limonene has been found.—A. S.

Backhousia citriodora; Oil of ——. J. C. Umney and C. T. Bennett. Chem. and Drug., 1906, **68**, 738.

The oil of *Backhousia citriodora* now being placed on the narket in quantity, has the following characters: Sp. gr., ·895—0·898; refractive index, 1·4889; aldehydes principally citral), 94—95 per cent., as determined by bsorption with sodium bisulphite. The oil is either ptically inactive or slightly lævo-rotatory; it is soluble n 2½—3 volumes of 70 per cent. alcohol, and distils lmost entirely between 215° and 230° C. The characters of the first and last fractions obtained on distillation are as follows:—

	First 10 per cent.	Last 5 per cent.	Residue (5 per cent.)
Specific gravity ..	0·886	0·895	—
Refractive index .	1·4798	1·4907	1·5132

The oil should not be confounded with that obtained from *Eucalyptus citriodora*, which latter consists almost entirely of citronellal. (See also this J., 1905, 689, 749.) —A. S.

Rosemary oil. E. J. Parry and C. T. Bennett. Chem. and Drug., 1906, **68**, 671.

The authors have examined oils distilled from authentic specimens of rosemary herbs from Spain and France, and the results show that contrary to the opinion gener-ally held, genuine oils may be lævo-rotatory, or if dextro-rotatory, may yield lævo-rotatory fractions on distillation. In France the oil is usually distilled from plants collected after the flowering period (February and March) and dried for about eight days in the sun, but in Spain distil-lation is carried on throughout the year and with both fresh and dried herbs. The fresh herb yields from 0·4 to 0·75 per cent. of oil, whilst the dried herb yields about 1 per cent. of oil of finer quality. The results obtained with three typical samples of oil are shown in the follow-ing table:—

	1 (Spanish).	2 (French).	3 (French).
Source of oil	leaves alone	stalks (nearly 60%) + leaves	leaves alone
Specific gravity	0·917	0·897	0·914
Optical rotation	+5° 30′	—8° 30′	—3°
Esters, as bornyl acetate	3·2%	3·0%	3·6%
Total borneol	19·7%	10·9%	18·5%
Optical rotation of first 10% on distillation at 100 mm.	—1	—12° 30′	—10°

The oils were fractionally distilled at 100 mm. pressure, and eight fractions, each 10 per cent. of the original quantity, collected. With sample No. 1, the first three fractions were lævo-rotatory and the others dextro-rotatory, whilst with Nos. 2 and 3 all the fractions were lævo-rotatory. The lævo-rotatory constituent (*l*-pinene) is present in larger quantity when the stalks are used with the leaves for the preparation of the oil; the leaves alone yield an oil with a finer odour and containing more borneol than when both leaves and stalks are employed. —A. S.

Borneol and bornyl acetate from pinene hydrochloride. J. Houben. Ber., 1906, **39**, 1700—1702.

The author claims priority over Hesse in the formation of borneol from pinene hydrochloride by the action of free oxygen on pinene-magnesium hydrochloride (this J., 1906, 390). Bornyl acetate can be obtained by treating pinene-magnesium hydrochloride, after oxidation, with acetic anhydride.—F. Shdn.

Nerol and its preparation from linalool. O. Zeitschel. Ber., 1906, **39**, 1780—1792.

The work of the author and previous observers on the action of acetic anhydride or other acid reagents on linalool shows that linalool suffers isomeric change into nerol as well as into geraniol and terpineol. Geraniol and nerol are most probably space isomerides, the follow-ing being their respective formulæ:—

$$CH_3.C.CH_2.CH_2.CH:C(CH_3)_2$$
$$CH_2(OH).\ddot{C}.H$$

Geraniol.

$$CH_3.C.CH_2.CH_2.CH:C(CH_3)_2$$
$$H.\ddot{C}.CH_2.OH$$

Nerol.

These formulæ are confirmed by the fact that terpin hydrate is more rapidly formed from nerol than from geraniol. It follows, also, that citral *b* is the aldehyde of nerol, and citral *a* the aldehyde of geraniol. Linalool (Barbier's licarhodol) was heated to 140° C. with acetic anhydride. The product on saponification yielded geraniol and nerol. The same products were obtained by using, instead of acetic anhydride, formic acid or acetic acid with sulphuric acid, or dilute mineral acids. Citral was reduced with sodium amalgam in alcohol, the solution being kept slightly acid, nerol and geraniol being thus formed. If nerol is oxidised with chromic acid some citral is obtained. Geraniol, linalool and nerol are all more or less converted into terpin hydrate on prolonged shaking, the relative velocity being 1(geraniol):5(linalool): 9(nerol).—F. Shdn.

Nerol; Identity of artificial and natural ——. H. v. Soden and W. Treff. Ber., 1906, **39**. 1792—1793. (See this J., 1906, 334.)

Nerol was prepared by the action of acetic anhydride and sodium acetate on linalool. This was purified from geraniol by the method used to obtain pure nerol from oil of petitgrain (*loc cit.*). The properties and derivatives of the artificial nerol agreed in every respect with those found for the nerol isolated from petitgrain oil.
—F Shdn.

Diphenyl or alkylphenyl camphomethane and methylene. A. Haller and E. Bauer. Comptes rend., 1906, **142**, 971—976

Diphenylcamphomethylene $C_8H_{14}\begin{matrix}C{:}C(C_6H_5)_2\\ CO\end{matrix}$ was prepared by heating camphor with sodium amide in ether and then adding benzophenone. On fractionating, a yellow liquid passes over at 250° C. at 15 mm., which solidifies on cooling. After crystallising from ether and petroleum spirit, fine octahedra are obtained, melting at 113·5° C. and with $[\alpha]_D = +287°$. This substance can be also prepared from diphenylcamphocarbinol. The carbinol is formed by the interaction of the organo-magnesium compound of monobromcamphor and benzophenone in ether. After standing, fine white crystals are deposited, melting at 122·5° C. and with $[\alpha]_D = +62°\ 49'$. The ethereal mother-liquor yields diphenylcamphomethylene on fractionation. If the carbinol be dehydrated by heating with formic or pyruvic acids, the chief product is an isomeric alcohol $C_{23}H_{26}O_2$, melting at 200° C. This substance forms a potassium salt soluble in water but insoluble in alkalis. A small quantity of the methylene compound is produced by the dehydration. Sodium amalgam reduces the methylene compound to diphenyl-camphomethane melting at 106°—107° C.—F. Shdn.

Esterification of alcohols and phenols. I. J. Houben. Ber., 1906, **39**, 1736—1753.

The alcohol or phenol, dissolved in ether, is treated with an organo-magnesium compound, when a replacement of the hydrogen of the hydroxyl takes place:— $R.OH + R^1MgI = R.OMgI + R^1H$. On treating the magnesium compound with acetic anhydride, or even acetyl chloride, the acetic ester is formed:—

$$R.OMgX + (CH_3CO)_2O = R.O.COCH_3 + CH_3.COOMgX.$$

Good results were not always obtained when iodine or bromine magnesium compounds were employed. But the chlorine magnesium compounds generally gave satisfactory results. The acetates of isobutyl alcohol, isoamyl alcohol, geraniol, linalool, terpineol and thymol were prepared; also the propionates of linalool and terpineol. Terpinyl acetate (b. pt. 115°—118° C. at 13 mm.) is a liquid as mobile as water, with an odour resembling that of lilies. Linalyl propionate is a colourless liquid boiling at 108°—111° C. at 12 mm., and 115°—119° at 16 mm. Terpinyl propionate boils at 119°—121° C. at 11·5 mm. *Cis*-terpin can be made by this method to yield terpin diacetate, boiling at 140°—141° C. at 10 mm. On distillation at ordinary pressure, terpin diacetate yields terpinyl acetate, and unsaturated hydrocarbons containing some dipentene. Polyvalent, solid and difficultly soluble alcohols can be esterified by this method—cellulose and starch for example.—F. Shdn.

Phenylation with copper as catalysor. I. Goldberg. Ber., 1906, **39**, 1691—1692.

Phenylanthranilic acid $C_6H_4(COOH)(NH.C_6H_5)$ can be readily prepared by the interaction of anthranilic acid, bromobenzene and potassium carbonate in the presence of a small amount of copper. Benzanilide, $C_6H_5CO.NH.C_6H_5$, and salicylanilide,

$$C_6H_4(OH)CO.NH.C_6H_5,$$

can also be formed by the same reaction.—F. Shdn.

Displacement of the acetyl by the methyl group by means of diazomethane. J. Herzig and J. Tichatschek. Ber., 1906, **39**, 1557—1559.

Diazomethane has no action on acetanilide or phenacetin. On the other hand *p*- and *m*-acetoxybenzoic acid are converted into *p*- and *m*-methoxybenzoic acid respectively (see J. Herzig and J. Tichatschek, Ber., 1906, 268). Thus it appears likely that in diazomethane we have a reagent to distinguish between the acetylamino and acetoxy group. The reaction is, however, not generally applicable to ortho-substituted hydroxyl bodies. Salicylic acid itself, when treated with diazomethane, yields principally gaultheria oil. Similarly, acetosalicylic acid (aspirin) yields salicylic acid acetyl ether methyl ester. Salol, on the other hand, yields salol methyl ether quantitatively, whilst acetylsalol remains unchanged.
—H. L.

Ketones; New method of formation of ——. H. Haehn. Ber., 1906, **39**, 1702—1704.

By heating monocarboxylic acids of the fatty series to a high temperature with calcium carbide, ketones are produced, water and carbon dioxide being separated.

$$2R.COOH = R.CO.R + CO_2 + H_2O.$$

The water reacts with the calcium carbide to form acetylene and calcium oxide or hydroxide. To carry out the reaction, a combustion tube is filled with calcium carbide in pieces of the size of a pea, and is heated in a combustion furnace. The acid is allowed to flow slowly into one end of the tube and the ketone is collected in a receiver connected to the other end. If the crude ketone have an acid reaction, either the distillation is being carried on too rapidly, or the carbide has not been heated to a sufficiently high temperature. Formic acid yielded by this process, water and carbon monoxide. Acetic acid yielded a mixture of acetone and a primary alcohol (probably methyl alcohol) having a constant boiling point of 62° C. From 50 grms. of propionic acid, 28 grms. of crude diethylketone were obtained (theoretical yield, 28 grms.). The yield of dipropylketone from butyric acid was 30 per cent. of the theoretical. Benzoic acid yielded benzophenone, the yield being improved by working in a vacuum of about 20 mm.—A. S.

Antimony tartrate and its ethyl ester. J. Bougault. J. Pharm. Chim., 1906, **23**, 465—469.

Further experiments show that even when antimony oxide is allowed to react with excess of aqueous tartaric acid in the cold, and the compound formed is precipitated with acetone, the product still has the composition, $C_4H_3O_6Sb$, as previously recorded (this J., 1906, 325). When thus prepared and dried in the air, it retains 1 mol. of acetone, which, however, is given up at 100° C. This anhydride, $C_6H_3O_6Sb$, is therefore the constant product of the reaction, and the acid, $C_4H_5O_7$, of P. Guntz, is non-existent. By treating the anhydride, in the cold, with a solution of tartaric acid in 95 per cent. alcohol, esterification gradually takes place and the ester formed, being less soluble, is gradually deposited, the crystallisation not commencing for eight or ten days, and continuing for several months. These crystals, in the form of very fine needles, often aggregated to spherules, dried at 100° C., have the formula, $C_4H_2O_6Sb.C_2H_5$. This ester is insoluble in all ordinary neutral solvents. It is slowly dissociated on contact with water. It is dissolved by neutral potassium tartrate solution, potassium ethyl tartrate and tartar emetic being formed, probably by the dissociation of the ester.—J. O. B.

Monazite sand; Best method of treating ——, *to obtain thorium and cerium.* Garelli. Sixth Internat. Congr. of Appl. Chem., Rome. Z. angew. Chem., 1906, 19, 895.

The sand is fused with sodium peroxide, or with a mixture of sodium and potassium chlorates. The fused mass is treated with sulphuric acid, and the solution thus obtained heated with ammonia, which precipitates ceric and thorium compounds. These are treated with oxalic acid, and separated by salicylic acid or sodium thiosulphate. This method requires less oxalic acid than the ordinary methods. The author proposes to use crude ceric salts, as energetic oxidisers, for bleaching wool, and also in purifying acetylene.—J. T. D.

Colloidal gold solutions; Formation of —— *with essential oils.* L. Vanino and F. Hartl. Ber., 1906, 39, 1696—1700.

Colloidal solutions of gold can be formed by the addition of gold chloride solution to water containing small quantities of the following substances:—Turpentine oil, pinene, rosemary oil (used formerly in the production of "potable gold"), potassium carbonate with formaldehyde, pinene, turpentine oil, or alcohol. The formation of the colloidal solution is accelerated by adding to the gold chloride solution a few drops of a gold solution already in the colloidal state.—F. Shdn.

Actinium; New product from ——. O. Hahn. Ber., 1906, 39, 1605—1607.

From thorium, itself inactive, is obtained radiothorium, which emits α-rays, and this is followed in turn by thorium X, the characteristic emanation, and the "active efflorescence." Actinium shows close analogy to thorium, save in the first step; and the author has now produced from actinium "radioactinium," by adding thiosulphate to a strongly acid actinium solution, when the precipitated sulphur carries down with it a substance which emits α-rays, though but little β-rays or emanation. The intensity of the α-radiation increases to a maximum in about three weeks, then falls to half value in 20 days. The β-radiation and the emanation follow a similar course.—J. T. D.

Essential oils; Sicilian and Calabrian ——. Schimmel's Report, April, 1906.

The statistics show that last year's export, as compared with that of the previous year, has suffered a falling off amounting to 137,859 kilos., value 1,048,830 lire, or about 14 per cent. This reduction in the export is not, however, in any way due to a decline in the demand from abroad, but must be attributed to the fact that with the comparatively feeble crops of the winter season 1904—1905, smaller quantities of oil were available for the export than in the preceding year. It has probably never happened before that the market has passed over from one season into another with stocks of all kinds of essences completely cleared out, as was the case in the autumn of 1905. [T.R.]

Cinnamon oil. Schimmel's Report, April, 1906.

The price of fine Ceylon cinnamon-chips is practically unchanged. The figures of the export in 1905 again show a considerable increase, the total being 2,235,395 lb. (of which the United Kingdom took 358,146 lb.), as against: 2,135,220 lb. in 1904; 2,160,352 lb. in 1903; and 1,763,679 lb. in 1902.

Citronella oil. Schimmel's Report, April, 1906.

The shipments in 1905 from Colombo and Galle were 1,282,471 lb., of which the United Kingdom took 398,700 lb.: the shipments in 1904 were 1,133,068 lb.; in 1903, 1,027,486 lb.; and in 1902, 1,294,750 lb.

On the other hand, the January shipments, of a total of only 19,618 lb., show a great falling off, as compared with a monthly average export of about 100,000 lb.; this appears to explain the lack of available goods and the high price of the same. In Ceylon, the distilling came to an end in December, and as all the labourers are employed on the rice-fields in January, the work on the citronella grass-fields ceased for the time being. Stocks are already cleared out, and oil for early delivery is all contracted for, so that only later deliveries come under consideration. It is therefore possible that the position may become more acute, and that the adjustment between supply and demand will only take place when stocks have again accumulated in the principal consuming countries.

Under these circumstances it is for the present out of the question that prices will go back, much less than the values formerly considered normal will again be reached. [T.R.]

Alkaloids; Precipitation and determination of —— *with potassium bismuth iodide.* D. Jonescu. XXIII., page 563.

English Patents.

Carbon tetrachloride and sulphur chloride; Manufacture of ——. E. Haworth and H. Baker, Runcorn, Lancs. Eng. Pat. 9404, May 4, 1905.

In the manufacture of carbon tetrachloride and sulphur chloride by passing chlorine gas, even containing considerable quantities of air, through carbon bisulphide, the residual gases are passed through liquid sulphur dichloride containing antimony chloride, or through a mixture of these two substances with sulphur monochloride. Chlorine mixed with air or other inert impurity can be passed into a mixture of sulphur monochloride and antimony chloride till more or less sulphur dichloride is formed. This is treated with carbon bisulphide and the mixture fractionally distilled to obtain carbon tetrachloride and sulphur monochloride.—F. Shdn.

Dialkylmalonic acids; Manufacture of diamides of ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat., 19,352, Sept. 25, 1905.

See Fr. Pat. 358,085 of 1905; this J., 1906, 197.—T. F. B.

United States Patents.

Carbon chlorides; Process of making ——. F. J. Machalske, Brooklyn. Assignors to F. Darlington, Great Barrington, Mass. U.S. Pat. 808,100, Dec. 26, 1905.

Oxychlorides of carbon (chloro-carbonic acid or perchloromethyl formate) are produced by heating a suitable mixture of quicklime, calcium chloride and carbon in an electric furnace in absence of air. The best proportions are those corresponding to the equation, $2CaO+2CaCl_2+10C=4CaC_2+2COCl_2$. The carbon oxychloride produced is passed through a series of towers containing a substance such as coke, bone charcoal or pumice, which, by the action of surface-contact, decomposes the oxychloride into carbon tetrachloride and carbon dioxide, thus: $2COCl_2=CCl_4+CO_2$. The tetrachloride is condensed in a worm cooled by water, whilst the carbon dioxide is drawn off and compressed.—J. F. B.

Alkamine esters of p-aminobenzoic acid. A. Einhorn, Munich, Germany. Assignor to Farbw. vorm. Meister, Lucius und Brüning, Hoechst a/Main, Germany. U.S. Pat. 812,554, Feb. 13, 1906.

p-Nitrobenzoylchloroethanol, obtained by the action of *p*-nitrobenzoyl chloride on ethylene-chlorhydrin, is heated for several hours at 100°—120° C. with diethylamine. Ten parts of the *p*-nitrobenzoyl-diethylaminoethanol so obtained are digested at a moderate temperature with 13 parts of tin and 25 parts of concentrated hydrochloric acid. The product, *p*-aminobenzoyl-diethylaminoethanol, is one of the class of alkamine esters of *p*-aminobenzoic acid now claimed. These esters, in the form of their hydrochlorides, are employed as local anæsthetics which are stated to have no irritating action.—J. F. B.

Carbon acids and ketones; Process of making ——. H. S. Blackmore, Mount Vernon, N.Y. U.S. Pat. 817,690, April 10, 1906.

Carbon dioxide is mixed with a hydrocarbon such as methane, and the mixture is heated to a temperature near-

that at which dissociation of carbon dioxide takes place. At this temperature the hydrocarbon is oxidised by the oxygen of the carbon dioxide with the production, in the case of methane, of a mixture of acetic acid and acetone. The relative proportions of the products depend on the proportions of the reacting gases and on the temperature employed. The use of an excess of methane and a very high temperature favour the production of acetone. The reaction between the mixed gases takes place in a closed cylinder in which the desired temperature is maintained by the presence of diaphragms of platinum gauze heated by electricity. The products of the reaction are drawn away and condensed as fast as they are formed. The temperature must not exceed the dissociation temperature of the products.—J. F. B.

Formates; Process of making ——. J. Weise, F. Rieche and A. Barth, Assignors to R. Koepp und Co., Oestrich on Rhine, Germany. U.S. Pats. 820,159, 820,373 and 820,374, May 8, 1906.

See Fr. Pat. 342,168 of 1904; this J., 1904, 911.—T. F. B.

French Patents.

Malonyl-p-phenetidine; Process of making dialkylated derivatives of ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 360,864, March 15, 1905.

See Eng. Pat. 4564 of 1905; this J., 1905, 1188.—T. F. B.

Theobromine barium; Process of making an easily soluble double salt of ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 360,904, March 17, 1905.

See Eng. Pat. 4959 of 1905; this J., 1905, 1188.—T. F. B.

Dimethyl- and trimethylxanthine; Process of making double salts of ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 360,909, March 18, 1905.

See Eng. Pat. 4958 of 1905; this J., 1905, 1254.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 485.)

English Patent.

Development of photographic plates, films and the like. W. F. C. Kelly, Fulham. Eng. Pat. 3164, Feb. 15, 1905.

The invention relates to the use of a single tablet containing all the materials necessary for developing photographic plates: the following example is given for a tablet suitable for developing a quarter-plate:—Metol, 2 grains; quinol, 4 grains; potassium metasulphite, 0·5 to 1 grain; borax, 10 to 20 grains, and sufficient colloid and glycerin or glucose to mould the tablet.—T. F. B.

French Patents.

Illuminating compositions for photography in artificial light. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses Fils. Fr. Pat. 360,588, March 2, 1905.

Compositions for producing artificial illumination for photographic purposes are obtained by mixing magnesium, with or without aluminium, with the chromate of a metal which has two degrees of oxidation, *e.g.*, iron, aluminium, copper, manganese. The following mixtures may be used:—Magnesium, 2—3 parts; manganese chromate, 1 part; magnesium, 2 parts; copper chromate, 1 part. Such mixtures are stated to produce a highly actinic flame on ignition, and to evolve very little smoke.—T. F. B.

Reproduction of models, pictures, writing, &c.; Process for the multiple ——. Neue Photographische Ges. Fr. Pat. 360,826, March 13, 1905.

The design, &c., which it is desired to reproduce is drawn upon paper with a substance which resists, wholly or partially, the action of the liquid or gas which is to be used for making the copies. Such liquids and gases are, for example, ammonia, halogens, oxides of nitrogen, acetic acid, alcohol, &c. As an example of the process, the design is drawn on paper with dextrin, a layer of asphaltum varnish is applied, and the paper is washed with water, which removes part of the dextrin, leaving a "negative pattern." The paper which is to receive the reproduction is then prepared with a substance which is coloured or changed in colour by the reacting liquid; using ammonia for this purpose, the paper may be prepared with turmeric, a manganese salt or a mercury salt. If the pattern be made by simply drawing the design with asphaltum varnish, and the receiving paper be coated with alkaline phenolphthalein, and acetic acid used for the treatment, a red design on a white ground is produced. Numerous other examples of the process are given in the specification.—T. F. B.

Photographic pictures; Process for decomposing —— into grained images. Klimsch et Cie. Fr. Pat. 360,697, Dec. 20, 1905.

It is claimed that photographic positives, produced by printing from a negative on to a bichromated gelatin or albumin surface, are converted into grained positives by evaporating on the surface of the positive a solution of resin, oil, fat, &c. It is stated that the resin is separated into minute globules or points, exactly corresponding in size and arrangement to the details of the positive.

—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

(*Continued from page* 498.)

Nitroglycerin; Freezing and melting of ——. Kast Sixth Internat. Congr. of Appl. Chem. Z. angew Chem., 1906, **19**, 850.

Nitroglycerin has two melting-points, 2°·8 and 13°·5 C. The less stable modification melts at the lower temperature. Both forms are monotropic.—J. T. D.

Nitroglycerin; Production of —— of low freezing-point. Will. Z. angew. Chem., 1906, **19**, 899—900.

When glycerin is heated for 7—8 hours to 290°—295° C., and any water produced is removed, it is converted to the extent of 25—45 per cent. into diglycerin, a small amount (4—6 per cent.) of tri- or polyglycerins being also produced. By fractional distillation under reduced pressure, the diglycerin can be isolated as a colourless, very viscous, sweet-tasting liquid, boiling at 245°—250° C. under 8 mm. pressure. It can be nitrated exactly like glycerin, and gives a nitro-product almost identical in explosive properties with trinitroglycerin, save that it is somewhat less sensitive to shock. If about 25 per cent. of this substance be mixed with nitroglycerin, (or if a mixture of glycerin with 25 per cent. of diglycerin be nitrated), an explosive is obtained with all the properties of nitroglycerin, but remaining fluid at – 15° or – 20° C.

—J. T. D.

Explosives; Addition of charcoal to ——. L. Mommi. Sixth Internat. Congr. of Appl. Chem. Z. angew. Chem., 1906, **19**, 850.

The usual explosives give carbon dioxide and water vapour. If charcoal be added, the gases formed are carbon monoxide, hydrogen, and nitrogen. The temperature is considerably lowered by this, and the corrosion of the gun materially lessened.—J. T. D.

Smokeless powder; Residue from explosion of ——, *and its influence on the rusting of guns.* G. van Pittius. Sixth Internat. Congr. of Appl. Chem. Z. angew. Chem., 1906, **19**, 848—850.

None of the substances contained in the residue from either nitroglycerin powder or nitrocellulose powder is in itself injurious to the gun; but they may become so in presence of moisture. The gun should, therefore, be washed out

as soon as possible after use, and where that is not possible, a greasy cleaning-rod should be put through it to keep moisture from the hygroscopic residue.—J. T. D.

Phosphorus; Method of detecting minute quantities of white ——. R. Schenck and E. Scharff. VII., page 535.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 500.)

APPARATUS, ETC.

Parting apparatus; New form of platinum ——. A. Jarman. Inst. of Min. and Metall., May 17, 1906.

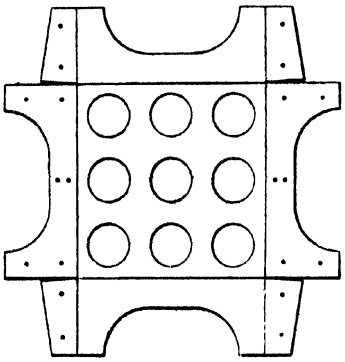

FIG. 1.

THE new form, designed by Liversidge, is much less expensive in platinum and simpler in construction than the usual form described in Percy's "Metallurgy of Silver and Gold." The mode of construction is obvious from the plan (Fig. 1) and the photograph (Fig. 2). Fig. 1 shows the apparatus in plan of ⅜rds scale, each hole being ⅜ in. in diameter. It is made of platinum 0·006 in. thick, and the joints may either be gold-soldered or riveted as indicated on the plan. A glass beaker is used as the boiler, and the legs of the stand are 2 mm. longer than the thimbles, which are thus suspended, by their turned-out lips, with 2 mm. of acid between them and the bottom of the beaker, so that free circulation of the acid can occur. The cost is about £9 13s. 6d. for a 9-cup tray with thimbles.

The pin apparatus, shown in Fig. 3, is in most respects preferable to a tray and thimble apparatus; the acid

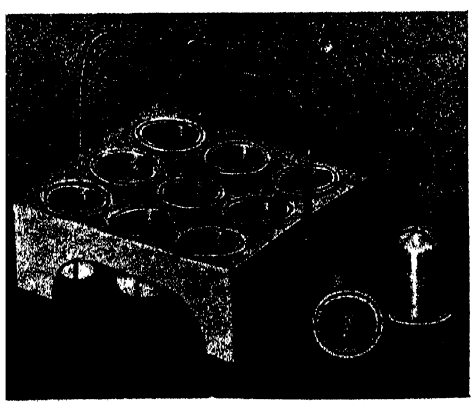

FIG. 2.

FIG. 3.

has freer access to the cornets, and the progress of the operation can be watched. The apparatus shown, which is made of gold, has the disadvantage that the cornets have to be removed on to a tile for annealing, as they might stick to the frame if it were heated with them; but that could be obviated by making the frame of platinum.—J. T. D.

ENGLISH PATENT.

Gas-analysis; Apparatus for use in ——. C. A. Hartung, Berlin. Eng. Pat. 17,708, Sept. 1, 1905, Under Int. Conv., Sept. 2, 1904.

IN this improved apparatus for gas-analysis, the gas is drawn from a pipe branched from, and returning to, the main current. The gas is drawn off by a hydraulic pump and then forced through a vessel containing absorbents, and the reduction in volume read off or recorded. The absorption vessel is then opened automatically to the atmosphere. The required volume of gas is pumped by a uniformly rising and falling liquid column. This rising and falling is maintained by a constant flow of water and an intermittent siphon. The cylinder of the gas-pump is connected with a hydraulic valve so that constant volumes of gas are pumped into the absorption vessel. The size and position of the siphon can be adjusted. By means of a three-way cock the apparatus can be connected simultaneously to a burette or to a registering device.—F. SHDN.

INORGANIC—QUANTITATIVE.

Ammonium tri-iodate as fundamental standard substance in volumetric analysis. E. Riegler. Sixth Internat. Congr. of Appl. Chem. Z. angew. Chem., 1906, **19**, 845—846.

AMMONIUM tri-iodate is a well-crystallised, anhydrous, non-hygroscopic substance, stable both as solid and in solution, and of well ascertained composition. It is prepared by dissolving 100 grms. of pure iodic acid in 200 c.c. of hot water, filtering if not perfectly clear, adding either 10 grms. of pure ammonium chloride or 3 grms. of ammonia (NH_3) in the form of strong ammonia solution, and allowing to stand for 24 hours. The separated tri-iodate is pure, but may be re-crystallised if desired, by dissolving in four times its weight of boiling water and allowing to cool. Its use in standardising sodium thiosulphate solution, or for other purposes where a definite quantity of free iodine is required, is obvious from the equation, $(NH_4)H_2(IO_3)_3+15KI+16HCl=15KCl+NH_4Cl+9H_2O+9I_2$. One molecule sets free nine molecules of iodine, so that 3·025 grms. per litre forms a decinormal solution. To standardise thiosulphate solution, about 1 grm. of potassium iodide is dissolved in 40 c.c. of water, and 1 c.c. of concentrated hydrochloric acid and 10 c.c. of the tri-iodate solution are added; the thiosulphate is then run in and the titration

finished with starch as usual. The solution can also be used directly, without acid, according to the equation:—

$$3\{(NH_4)H_2(IO_3)_3\} + 6Na_2S_2O_3 = 3Na_2S_4O_6 + 5NaIO_3 + NaI + 3NH_4IO_3 + 3H_2O;$$

in this case 27·234 grms. per litre forms a decinormal solution.

The same solution is, it will be seen, alkalimetrically equivalent to a decinormal solution of iodic acid, and can be used to standardise alkali hydroxide solutions; the best indicators are luteol (0·2 grm. in 100 c.c. of alcohol), Congo Red (0·1 grm. in 90 c.c. of water and 10 c.c. of alcohol), Alizarin Red (0·1 grm. in 100 c.c. of water). Alkalimetric titrations can also be done by adding a known volume of the alkali solution to a known volume, more than equivalent, of the tri-iodate, and ascertaining the amount of the latter not neutralised which remains, by titration with thiosulphate solution.

Ammonium tri-iodate decomposes hydrazine sulphate according to the equation:—

$$2\{(NH_4)H_2(IO_3)_3\} + 9N_2H_4H_2SO_4 = (NH_4)_2SO_4 + 8H_2SO_4 + 6HI + 18H_2O + 9N_2;$$

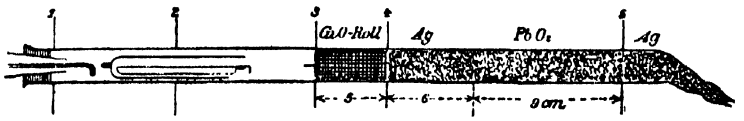
and measurement of the nitrogen evolved affords a method of ascertaining the strength of a tri-iodate solution. —J. T. D.

Iron; Detection and determination of minute quantities of ——. A. Mouneyrat. Comptes rend., 1906, **142**, 1049—1051.

To 50 c.c. of the extremely dilute solution of iron salt, 3 c.c. of ammonia solution free from iron (62 grms. of NH_3 per litre) are added and hydrogen sulphide is passed through for 10—12 minutes. A dark-green solution is formed, apparently containing the iron in a colloidal condition; and the amount of iron present can be determined colorimetrically by comparison with solutions of known strength. Mineral acids and many inorganic salts destroy the green colour; but many organic substances—glycerol, cane-sugar, dextrose, mannitol, lactic acid, tartaric acid, or citric acid, and especially albumin—increase the stability of the colloidal state and the sensitiveness of the reaction. Iron can be detected by this method in a solution containing 1/800,000.—J. T. D.

Gold; Determination of small quantities of ——, *colorimetrically.* R. N. Maxson. Z. anorg. Chem., 1906, **49**, 172—177.

The intensity of the colour of red colloidal gold solution is proportional to its concentration, and small quantities of the metal may be estimated colorimetrically in this manner. The solution of gold, as chloride, is evaporated on the water-bath if necessary to get rid of acid, and an aqueous solution of acetylene, obtained by dissolving the washed gas in water, added. After development of the red colour, the solution is shaken and then compared with a standard. The colour meter recommended consists of vertical tubes in a dark box illuminated from below by means of a mirror. The bulk of solution must be kept small if very little gold is present, or the colour may not appear. Traces of electrolytes cause coagulation of the gold, but this may be prevented by adding a few drops of ether. The standards remain unchanged for weeks, if free from electrolytes, and the method is a rapid one.—F. Sodn.



Babbitt [anti-friction] metal; Rapid method for the analysis of ——. H. Yockey. J. Amer. Chem. Soc., 1906, **28**, 646—648.

About 1 grm. of the filings or borings are evaporated with 20 c.c. of nitric acid (1:2) to dryness on the water-bath, and the residue then heated for one hour at a temperature of 120° C. for one hour. The residue is moistened with nitric acid, boiled with water for five minutes and the oxides of antimony and tin collected on a filter. After washing with hot water, the filter and its contents are dried, ignited, and weighed, the weight giving the antimony and tin oxides present. The filtrate is diluted to 250 c.c., of which 50 c.c. are treated with 10 c.c. of ammonia (1:1) and 6 c.c. of glacial acetic acid, boiled and the lead titrated with standardised ammonium molybdate solution, using tannin solution as indicator. The remaining 200 c.c. of the filtrate are neutralised with sodium carbonate until a precipitate forms, 1 or 2 c.c. of ammonia are added, and if a blue coloration appears, denoting the presence of copper, the solution is titrated with a standardised potassium cyanide solution until the blue colour disappears. The lead carbonate and hydroxide present do not interfere with the titration. In a second weighed portion of the sample the antimony is determined, the method described by Walters and Apfelder (this J., 1903, 927) being employed for this purpose.—W. P. S.

INORGANIC—QUANTITATIVE.

Copper oxide layer, 5 cm. long, in ultimate organic analysis; Use of ——. J. Marek. J. prakt. Chem., 1906, **73**, 359—373.

The principle of this method of combustion is the use of a roll of copper gauze 5 cm. long and 2 mm. smaller in diameter than the combustion tube. This gauze is so tightly packed round with asbestos in the tube that all the gases are compelled to pass through the copper oxide and not merely over it. The copper oxide being kept out

of contact with the glass greatly increases the life of the tube. Complete combustion is obtained with a moderate current of oxygen (30—35 c.c. per min.). The portion of the tube containing the copper oxide is wrapped round with asbestos and a tube of sheet iron slipped over. The combustion tube is of Jena glass, 20 mm. diameter, drawn off at one end and bent slightly downwards. The narrow end is completely filled with silver shavings, a device which obviates warming the tube at the end of the combustion; 3—4 cm. behind the silver is the copper oxide gauze. If nitrogen, halogens and sulphur are absent, a tube 30 cm. long will suffice. If these elements are present, a layer 8—10 cm. long of lead peroxide is placed in the tube between plugs of silver shavings. 1, 2, 3, 4 and 5 are perforated plates which serve as supports. The portion of the tube containing the peroxide can be made to pass through an air-bath heated to 180°—200° C., the temperature being kept constant before, during and after the combustion. The portion of the tube where the substance is burned, lies in a trough of iron wire gauze. The copper oxide is heated by a Teclu or Bunsen burner 3 cm. in width, no furnace being necessary. Uniform heating is obtained by means of iron plates covered with asbestos. The substance is placed in a porcelain boat inside a tube of hard glass. The oxygen is passed into the tube through the vertical arm of a T-tube. A thick iron wire passes through the horizontal arm, and by its use the boat can be moved or uncovered to burn off any residue of carbon. Accurate and concordant results were obtained for sugar, benzoic acid, antipyrine, quinine sulphate, &c., the actual combustion lasting from 10—40 mins. For highly volatile liquids, such as ether, the following arrangement was used: The vessel A has a capacity of about 80 c.c. B is a thick iron wire ending in a plate, *d*; *f* is a roll of thick iron wire gauze 1 cm. long. The tube T, which is introduced into the stopper of the combustion tube, is packed with silver shavings. The sealed bulb containing the substance is placed inside and oxygen passed through c and A to T. The tap C is then turned to the position shown in the figure and the bulb

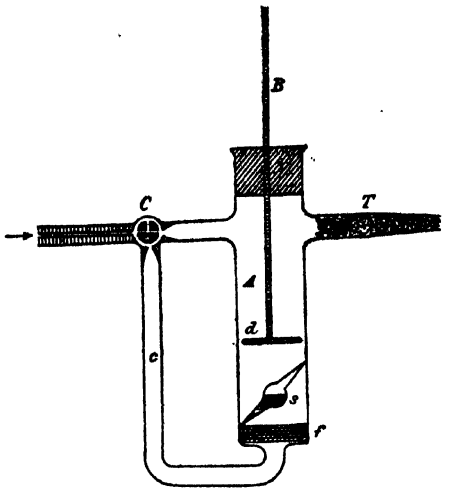


Fig. 2.

broken. After half to one hour the tap is turned to the left through a right angle and oxygen led through for another half hour, followed by air. To remove all traces of the substance the vessel is slightly warmed.—F. Shdn.

Hydrogen, carbon and sulphur in organic compounds; Electrical method for the simultaneous determination of ——. H. N. Morse and C. W. Gray. Amer. Chem. J., 1906, **35**, 451—458.

This paper is a continuation of work by Morse and Taylor (this J., 1905, 753), making the method of electrical heating applicable to a determination of sulphur along with carbon and hydrogen. The modifications necessary for this are as follows:—A platinum boat containing a weighed amount of dry lead peroxide is introduced near the end where the gases enter the absorption apparatus. A "graphited" porcelain tube containing asbestos mixed with lead peroxide is placed between the combustion tube and the absorption apparatus; this completes the absorption of any oxides of nitrogen and is kept heated electrically at 175° C. The lead peroxide in the boat is partially converted into lead nitrate and lead sulphate. After the combustion is finished, the boat and its contents are placed in a hard glass tube and ignited in a current of nitrogen, which decomposes the lead peroxide and nitrate, yielding lead oxide. The weight of sulphate present can be calculated after weighing the lead oxide obtained by heating a weighed quantity of lead peroxide.—C. E. F.

Valonia; Determination of extraneous matter in ——. A. Turnbull. Manchester, Liverpool and District Tanners Federation Year Book, 1906, 107—108.

The following is a quick method of estimating the "dirt," mainly consisting of limestone and sand contaminated with iron, which is often present in valonia beard, and which is dissolved by acid tan-liquors with disastrous results to the leather, especially when much iron is present.

A quantity of valonia is added to a calcium chloride solution (sp. gr. about 1·4) in a pear-shaped separating funnel, fitted with a wide-bore stopcock. After careful shaking, the mixture is allowed to settle; the dirt sinks and is run into a basin and washed, ignited and weighed. The ash is treated overnight with N/1 hydrochloric acid, filtered and titrated back with N/1 sodium carbonate. The amount of hydrochloric acid neutralised by mineral dirt is calculated to calcium carbonate. The solution is made up to a definite volume with distilled water and iron estimated in an aliquot part.—H. Bn.

Alkaloids; Precipitation and determination of —— with potassium bismuth iodide. D. Jonescu. D. pharm. Ges. Ber., 1906, 130; Chem.-Zeit., 1906, **30**, Rep., 156

Thoms has shown that potassium bismuth iodide can be used for the determination as well as the precipitation of alkaloids. Two grms. of quinine were dissolved in 50 c.c. of 10 per cent. sulphuric acid, and precipitated with potassium bismuth iodide. The precipitate was filtered off with suction and well washed with 5 per cent. sulphuric acid. The moist precipitate and filter were transferred to a wide-mouthed stoppered cylinder, 200 c.c. in capacity, and mixed with 20 grms. of sodium carbonate crystals which had been triturated with 40 c.c. of 10 per cent. sodium hydroxide. The alkaline liquid was shaken with 50 c.c. of ether, 25 c.c. of which were drawn off and evaporated in a tared vessel. From 1 grm. of quinine 0·9405 grm. was recovered in this way. The same process can be used for caffeine, but the alkaline liquid must be shaken out with chloroform. From 1 grm. of substance 0·9546 grm. was recovered. Antipyrine was determined in the same way as caffeine, but the precipitate required an hour's shaking with 20 grms. of sodium carbonate and 60 c.c. of 10 per cent. sodium hydroxide; 1 grm. of antipyrine left behind 0·9273 grm. of residue.—F. Shdn.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 501.)

Light; Hydrolytic action of ——. G. Ciamician. Sixt Internat. Congr. of Appl. Chem. Z. angew. Chem 1906, **19**, 850.

In aqueous solution, under the influence of light, aceton is converted into methane and acetic acid, methyl-ethyl ketone into ethane and acetic acid. Menthone gives th decilic acid which Wallach obtained from menthonoxim and at the same time an aldehyde isomeric if not identic with citronellal. Should the reverse reactions be pro ducible by light, the matter will have considerable interes for vegetable physiology.—J. T. D.

Hydrate formation; Relation between —— and temperatu coefficient of conductivity in aqueous solutions. H. Jones. Amer. Chem. J., 1906, **35**, 445—450.

The electrical conductivity of a solution increases with ris of temperature. The increase is due to a diminution i viscosity and to the decrease in the number of wate molecules which are attached to the ions. A review c work already published by the author and his co-worker on the hydrates which are present in aqueous solution leads to these conclusions. The temperature coefficient of conductivity of aqueous solutions are greater the strong is the hydrate-forming power of the electrolyte, and th coefficients are of approximately the same order of magni tude for substances with the same hydrating power. Th calcium bromide or chloride have greater temperatu coefficients than potassium bromide or chloride.

The temperature coefficient of conductivity for an given substance increases with the dilution, and th increase is greatest for those substances with large hydra ing power.—C. E. F.

Water; Anti-catalytic actions of ——. G. Bredig and V Fraenkel. Ber., 1906, **39**, 1756—1760.

It has been previously pointed out (Z. Elektrochem, 190 **11**, 525) that the decomposition of diazoacetic ester b water: $N_2{:}HC.CO_2C_2H_5 + H_2O = HO.H_2C.CO_2C_2H_5 + N$ affords a ready means of measuring the catalyti effect of hydrogen ions, the reaction being greatly accel rated by the presence of small quantities of free acid. Th authors, in studying the catalysis in alcoholic solution have found that the presence of traces of water in th alcohol has a strong retarding influence on the decomp sition. The velocity of the reaction: $N_2{:}HC.CO_2C_2H_5 + C_2H_5OH = C_2H_5.O.H_2C.CO_2C_2H_5 + N_2$, under the catalyt influence of 0·00909-molar picric acid at 25° C. was dete mined (1) in absolute alcohol (prepared by Winkler method; this J., 1905, 1253), and (2) in absolute alcoh to which 0·18 per cent. by weight of water was adde

It was found that the addition of the water lowered the velocity constant of the reaction by about 22 per cent.

Traces of water exert a similar retarding effect on the decomposition of oxalic acid into water, carbon monoxide, and carbon dioxide, by the action of concentrated sulphuric acid. For example, the time required for the decomposition of a definite quantity of oxalic acid by sulphuric acid containing about 100 per cent. of H_2SO_4 is prolonged from 50 minutes to three hours by the addition of 0·05 per cent. of water.—A. S.

New Books.

TABLES RELATING TO THE TRADE OF BRITISH INDIA WITH BRITISH POSSESSIONS AND FOREIGN COUNTRIES, 1900-01 TO 1904-05. [Cd. 2915.] Price 1s. 4d.

THIS return contains statistics of the foreign trade of British India during the last five financial years. In 1904-05 the total value of the imports of merchandise (exclusive of Government stores) into British India by sea was £64,452,192, as compared with £56,548,862 in 1903-04, whilst the total value of the exports of merchandise of Indian produce and manufactures (exclusive of Government stores) was £102,752,000 as against £99,756,049 in the preceding financial year. The total of the imports into, and the exports from, British India by land and sea (inclusive of Government stores and treasure) amounted in 1904—05 to £222,263,547, as compared with £208,944,476 in 1903—04.

ANNUAL REPORT OF THE IMPERIAL DEPARTMENT OF AGRICULTURE FOR THE YEAR 1904—05. CALCUTTA Government Central Press. 1906. Price as.12, or 1s. 2d.

LARGE 8vo pamphlet, containing 126 pages of subject matter.

THE NATIONAL PHYSICAL LABORATORY. Parrott and Ashfield, Printers, The Causeway, Teddington. 1906.

REPORT for the Year 1905, of large 8vo size, and containing 57 pages of matter. The following is the List of Official Papers published during 1905 by the Laboratory, or communicated by members of the staff to scientific societies or institutions, or to the technical journals:—

"An Analysis of the Results from the Falmouth Magnetographs on 'Quiet' Days during the twelve years 1891 to 1902."—Phil. Trans. A, Vol. 204, 1905, pp. 373—406. By C. Chree, D.Sc., F.R.S.

"Alternating Stress Testing Machine."—Engineering, Feb. 17, 1905. By T. E. Stanton, D.Sc.

"On a New Type of Electric Furnace, with a Redetermination of the Melting point of Platinum."—Proc., Roy.Soc., Series A, Vol. 76, pp. 235—250. By J. A. Harker, D.Sc.

"On the Specific Heat of Iron at High Temperatures."—Proc. Phys. Soc., June, 1905; Phil. Mag., Oct., 1905. By J. A. Harker, D.Sc.

"The Types of Structure and the Critical Ranges on heating and cooling of High-speed Tool Steels under varying thermal treatment."—By H. C. H. Carpenter, M.A., Ph.D. Awarded the Andrew Carnegie Gold Medal at the May Meeting of the Iron and Steel Institute, 1905.

"On the Properties of a Series of Iron-Carbon-Nickel-Manganese Alloys."—Seventh Report to the Alloys Research Committee of the Institution of Mechanical Engineers. By H. C. H. Carpenter, M.A., Ph.D., P. Longmuir, and R. A. Hadfield.

"Photometric Tests of Street Lamps in Teddington."—"Electrician," April 28, 1905; "Journal of Gas Lighting," May 2, 1905. By C. C. Paterson.

"On the Construction of some Mercury Standards of Resistance, with a Determination of the Temperature Coefficient of Resistance of Mercury."—Phil. Trans. A, Vol. 204, 1905, pp. 57—120; "Collected Researches of the National Physical Laboratory," Vol. I., 1905. By F. E. Smith, A.R.C.Sc.

"On the Construction of a Cadmium Cell."—British Association Report, 1905. By F. E. Smith, A.R.C.Sc.

"Temperature Experiments on the Field Coils of Electrical Machines."—Engineering Standards Committee Report, Feb., 1905. By E. H. Rayner, M.A.

"On the effect of Temperature on Insulating Materials."—Engineering Standards Committee Report, May, 1905. By E. H. Rayner, M.A.

"Report on Temperature Experiments carried out at the National Physical Laboratory."—"Journal of Instn. of Elect. Engineers," Vol. 34, 1905, pp. 613—659. By E. H. Rayner, M.A., A.M.I.E.E.

"Report on Errors in Workmanship."—Published by the Engineering Standards Committee. By S. W. Attwell.

"On the Testing of Cast Iron and other Materials by the Ewing Permeability Bridge."—Communicated to the Institution of Electrical Engineers. "Page's Weekly," Dec. 29, 1905, p. 1421. By Albert Campbell, B.A.

DIE ELEKTROLYSE GESCHMOLZENER SALZE. Dritter Theil, Elektromotorische Kraft. Von RICHARD LORENZ, Ph.D. Professor für Elektrochemie und physikalische Chemie am eidg. Polytechnikum in Zürich. Wilhelm Knapp's Verlag. Halle a. S., 1906. Price M.10.

8vo volume, containing 311 pages of subject matter, with 75 illustrations, and followed by alphabetical indexes of authors and subjects. The leading themes discussed are as follows:—(A) POLARISATION. (1) Introduction, Historical, and earlier results; (2) Influence of Temperature; (3) of Current Density; (4) Disturbance through Depolarisation; (5) Depolarisation and Current-yield; (6) Time Phenomena; (7) Normal form of Polarisation Discharge; (8) Connection between Polarisation Discharge and the Presence of different Ions at the Electrodes; (9) Polarisation Discharges with Metallic Vapour Electrodes; (10) Electrocapillary Phenomena. (B) CELLS. (1) Historic, &c.; (2) Cells with Fused Chlorides, Bromides and Iodides; (3) Cells of the Daniell Type; (4) Concentration cells; (5) Thermo-electromotive Powers; (6) Alloy-potentials in connection with Fused Salts; (7) The Fuel Element with Fused Electrolytes. (C) ELECTROMOTIVE POWER AND HEAT OF CHEMICAL ACTION (FREE ENERGY). (1) Historic; (2) Theoretical; (3) Researches of Poincaré and Ostwald; (4) Lead Chloride; (5) Lead Bromide; (6) Silver Chloride; (7) Silver Bromide; (8) Silver Iodide; (9) Zinc Chloride; (10) Cadmium Chloride and Cadmium Bromide; (11) Cells with Solids; (12) The Hydrogen and Oxygen Explosive Mixture at High Temperatures. (D) DECOMPOSITION POTENTIAL. (1) Introduction; (2) Historic, &c.; (3) Decomposition potential in the case of Zinc Chloride; (4) of other Salts; (5) of Fused Lead Chloride; (6) Sodium Hydroxide. (E) THEORY OF IONS.

THE CHEMISTRY OF HAT MANUFACTURING. Lectures delivered before the Hat Manufacturers' Association by WATSON SMITH (1887—1888). Formerly Lecturer in Chemical Technology in the Owens College, Manchester, and of the Victoria University. Revised and edited by ALBERT SHONK. Scott, Greenwood and Son, 19, Ludgate Hill, London, E.C., 1906. Price 7s. 6d. India and British Colonies, 8s., other countries, 8s. 6d. net. D. van Nostrand Co., 23, Murray Street.

CROWN 8vo volume, containing 132 pages of subject matter, with 16 illustrations, and an alphabetical index of subjects. The lectures treat of the following subjects:—I. and II. Textile Fibres, principally Wool, Fur and Hair. III. and IV. Water: its Chemistry and Properties. Impurities and their Effects. Tests of Purity. V. Acids and Alkalis. VI. Boric Acid, Borax and Soap. VII. Shellac; Wood Spirit and the Stiffening and Proofing Processes. VIII. Mordants: their Nature and Use. IX. and X. Dyestuffs and Colours. XI. Dyeing of Wool and Fur; Optical Properties of Colours.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e.).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy. A form of application for this purpose will shortly be issued.

Members are invited to call the attention of the Editor to any errors or omissions which they may have noticed in the Annual Indexes, 1896—1905, as soon as possible, in order that they may be put right in the Decennial Index.

List of Members Elected.

June 22nd, 1906.

Bennett, A. E. J., 14, Franklin Street, Woburn, Mass., U.S.A., Leather Manufacturer.

Berry, A. J., 5, University Gardens, Glasgow, Student of Chemistry.

Brandt, H. O., 66, Sackville Street, Manchester, Merchant.

Caro, Dr. Nikodem, Meinekestr. 20, Berlin, Germany, Analytical Chemist.

Carveth, Dr. H. R., Niagara Electro-chemical Co., Niagara Falls, N.Y., U.S.A., Works Manager.

Chapman, E. A., 2, Kensington Park, Stapleton Road, Bristol, Works Chemist.

Clark, M. H., c/o Boston Rubber Shoe Co., Fells, Mass., U.S.A., Chemist.

Comber, A. W., Suramangalam, Salem District, South India, Manager, Magnesite Works.

Eaton, B. J., Inst. of Medical Research, Kuala Lumpur, Selangor, Fed. Malay States, Government Chemist.

Frank, Prof. Dr. A., Berlinerstrasse 26, Charlottenburg, Germany, Chemist.

Glasel, Dr. Charles J., Box 15, South Boston, Mass., U.S.A., Tanner.

Harris, Jonathan W., 250, South Clinton Street, Chicago, Ill., U.S.A., Chemist.

Hinckley, E. H., Saylesville, R.I., U.S.A., Foreman.

Irwin, John T., Cledford, Middlewich, Cheshire, Manufacturing Chemist.

Johnson, Charles C., c/o The Procter and Gamble Co., Ivorydale, Ohio, U.S.A., Chemical Engineer.
Johnston, A. McA., Box 108, Germiston, Transvaal, Metallurgical Chemist.
Lawrence, V. O., 801, Drexel Building, Philadelphia, Pa., U.S.A., Manager, Chemical Works.
Linder, S. E., Leodholt, The Drive, Buckhurst Hill, Essex, Analytical Chemist.
Lloyd-Willey, W. S., 5, Cottage Grove, Bow, London, E., Charcoal Manufacturer.
Lynch, W. D., 10, Pinckney Street, Boston, Mass., U.S.A., Analytical Chemist.
Pettee, Charles L. W., c/o Hartford Laboratory Co., Hartford, Conn., U.S.A., Chemist.
Preston-Jackson, J. W. A., Castleford, Yorkshire, Analyst.
Scheffer, Heinrich, 7, Conyngham Road, Rusholme, Manchester, Chemical Apparatus Manufacturer.
Spencer, F. W., c/o Standard Ammonia Co., 82, Pitt Street, Sydney, N.S.W., Australia, Works Manager.
Steel, S. J., 17, Great Tower Street, London, E.C., Analytical Chemist.
Wertheimer, M. A., Kaukauna, Wis., U.S.A., Paper Manufacturer.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the Journal depends.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

" 22,021 (1905). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of colouring matters of the triphenylmethane series. June 7.
" 6189 (1906). Lake (Chem. Fabr. Griesheim-Elektron). Manufacture of azo colouring matter. June 7.
" 7288 (1906). Dreyfus, and Clayton Aniline Co. Manufacture of sulphuric acids of the aromatic series. June 20.

[C.S.] 10,079 (1906). Meister, Lucius und Brüning. Manufacture of products soluble in water, fats and oils, from the salts which higher fatty acids and acids of the oleic series form with organic colour bases. June 7.

„ 10,323 (1906). Johnson (Badische Anilin und Soda Fabrik). Manufacture of salts of 1.2-diazonaphtholsulphonic acids. June 20.

„ 10,505 (1906). Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matters of the anthracene series. June 13.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 12,433. De Montlord. Flax treating apparatus. [U.S. Appl., May 29, 1905.]* May 28.

„ 12,517. Johnson (Badische Anilin und Soda Fabrik). Removal of colouring matter from dyed or coloured material.* May 29.

„ 12,573. Ellis. Winch drums for use in dyeing cloth goods. May 30.

„ 12,596. Gaebele. Manufacture of vegetable hair from the fibres of the cocoanut.* May 30.

„ 12,718. Minck, and Bremer Baumwollwerke. Obtaining fibres from cotton seed hulls and other similar waste products.* May 31.

„ 12,842. Friedrich. Method of washing and drying artificial threads.* June 1.

„ 13,334. Soc. Anon. de Blanchiment Teinture. Fabric printing machines. [Fr. Appl., March 31, 1906].* June 9.

„ 13,420. Serret. Manufacture of artificial waterproof silk. June 11.

„ 13,695. Ellis (Chem. Fabr. von Heyden). Manufacture of ketone sulphoxylates and ketone hydrosulphites.* June 14.

„ 13,752. Puchert and Puchert. Wool-fibre cleaning apparatus.* June 15.

„ 13,788. Ellis (Chem. Fabr. von Heyden). Manufacture of formaldehyde hydrosulphites and sulphoxylates.* June 15.

[C.S.] 11,294 (1905). Hasselmann. *See under* IX.

„ 15,065 (1905). Arundel and Higginson. *See under* II.

„ 14,193 (1905). Brown and Young. Impregnating or coating materials with a liquid or semi-liquid substance. June 13.

„ 16,583 (1905). Peessarer. Preparation of threads, films and laminæ from viscose. June 20.

„ 18,168 (1905). Hulme. Apparatus for printing calicoes and other woven fabrics. June 20.

„ 20,220 (1905). Hanitzsch. *See under* XIX.

„ 1296 (1906). Bottomley. Manufacture of boracic acid wool. June 7.

„ 3833 (1906). Haines and Whit-Gould. Washing apparatus. June 13.

„ 8313 (1906). Frankenberg. Manufacture of waterproof materials. June 20.

„ 10,094 (1906). Müller. Manufacture of lustrous bands, threads, strips and the like of viscose. June 7.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 12,401. Hausser. Production of oxides of nitrogen by means of explosion engines. [Ger. Appl., May 31, 1905.]* May 28.

„ 12,538. Gaillard. Apparatus for concentrating sulphuric acid.* May 29.

„ 12,618. Johnson (Chem. Fabr. Griesheim-Elektron). Manufacture of chromic acid. May 30.

[A.] 12,834. Jaubert. Oxygen generators. [Fr. Appl., June 5, 1905.]* June 1.

„ 13,012. Masson. Recovery of antimony and arsenic from ores, concentrates, tailings and slimes.* June 5.

„ 13,480. Elworthy. Manufacture of hydrogen and of mixtures containing the same. [Fr. Appl., June 17, 1905.]* June 12.

„ 13,579. Serpek. Production of compounds of aluminium and nitrogen.* June 13.

„ 13,615. McEwen and Astbury. *See under* II.

„ 13,828. Wolffenstein. Manufacture of hydrogen peroxide.* June 16.

[C.S.] 6611 (1905). Tee. Manufacture of white salt from rock salt. June 13.

„ 21,280 (1905). Ellis (Merck). Manufacture of a new lithium salt. June 13.

„ 22,080 (1905). Cellarius. Manufacture of sulphuric acid. June 30.

„ 23,841 (1905). Gaillard. Concentration of sulphuric acid. June 7.

„ 9793 (1906). Davis. Manufacture of alkaline prussiates. June 13.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 12,431. Fourcault. Apparatus for drawing glass. [Appl. in Denmark, June 8, 1905.]* May 28.

„ 12,603. Fourcault. Apparatus for drawing glass. [Appl. in Denmark, June 8, 1905.]* May 30.

„ 12,815. Fourcault. Apparatus for drawing glass. [Appl. in Denmark, June 8, 1905.]* June 1.

„ 13,296. Beckett and Eaton. Glazing and enamelling clayware. June 9.

„ 13,472. Meakin, Ltd., and Jackson. Kilns for firing or drying ceramic and similar wares. June 12.

[C.S.] 22,335 (1905). Bundy. Production of marbled effects on glass, porcelain, &c. June 7.

IX.—BUILDING MATERIALS, CLAYS, MORTARS AND CEMENTS.

[A.] 12,353. Bougleux. Manufacture of cement.* May 28.

„ 12,621. Schumacher. Method of increasing the binding power of silicates of lime. May 30.

„ 13,007. Bale. Materials for laying and absorbing dust. June 5.

„ 13,232. South, Payne and Payne. Cement.* June 8.

„ 13,267. Atkinson. Production of cement. June 8.

„ 13,355. Suski. Binding agent. June 9.

„ 13,855. Reade. Compounds for treating wood for preventing and arresting dry rot. June 16.

[C.S.] 11,294 (1905). Hasselmann. Impregnation of wood and textile or fibrous substances to prevent putrefaction, rot and fungus. June 7.

„ 11,696 (1905). Carr and Unwin. Manufacture of firebricks. June 13.

„ 15,582 (1905). Hoffmeister, Hundt, Eifler and Winther. Artificial stone and the like. June 13.

„ 23,695 (1905). Melville. Floor and wall covering material. June 20.

„ 1458 (1906). Surmann. Manufacture of briquettes, blocks, artificial stone and the like. June 13.

„ 3477 (1906). Böseken. Production of artificial marble. June 13.

X.—METALLURGY.

[A.] 12,395. Wallin. *See under* XI.

„ 12,599. Gouber. Soldering aluminium and its alloys and solder therefor. May 30.

„ 13,012. Masson. *See under* VII.

[A.] 13,127. Cowper-Coles. *See under* XI.
„ 13,186. Birmingham. Alloys.* June 7.
„ 13,189. Soc. Electrométall. Française. Manufacture of decarburised cast iron. [Fr. Appl., Aug. 5, 1905.]* June 7.
„ 13,400. Jenkins. Soldering paste.* June 11.
„ 13,499. Mills. Manufacture of steel. June 12.
„ 13,541. Aspinall. Furnaces for smelting metals. June 13.
„ 13,655. Cowper-Coles. Process for coating and alloying one metal with another. June 14.
„ 13,845. Newton Bros., and Newton. Magnetic separation. June 16.
C.S.] 13,811 (1905). Davies and Clark. Welding iron and steel with each other or with other metals and fluxes therefor. June 13.
„ 15,809 (1905). Taylor and Mudford. Treatment of steel. June 7.
„ 17,250 (1905). Windhausen. Concentrating or separating ores and metals. June 13.
„ 17,370A (1905). Leggo. Rabble shafts and arms for furnaces for roasting, desulphurising, dehydrating or drying ores and other substances. June 7.
„ 26,076 (1905). Babé and Louvrier. Metallurgical furnaces. June 20.
„ 494 (1906). Delporte. Refining iron in a Siemens-Martin furnace. June 13.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 10,802A. Cowper-Coles. Electrolytic deposition of metals. June 12.
„ 12,395. Wallin. Method of obtaining metals from ores or for heating substances in electric furnaces, and electric furnaces for use therewith.* May 28.
„ 13,023. De Hemptinne. Process for oxidising liquids with aid of electric discharges. June 5.
„ 13,127. Cowper-Coles. Electrolytic refining of copper. June 6.
„ 13,699. Cowper-Coles. Electro-deposition of iron. June 14.
C.S.] 10,120 (1905). Schiele. Electroplating of metals. June 20.
„ 12,253 (1905). Kelley. Electric accumulator plates. June 20.
„ 16,570 (1905). Hartung. Storage batteries. June 7.
„ 19,035 (1905). British Thomson-Houston Co. (General Electric Co.). Insulating material. June 20.
„ 26,876 (1905). Boult (Stebbins). Secondary batteries. June 7.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

[A.] 11,950A. Zonca. Devices for separating oil from its emulsions.* June 1.
„ 12,404. Buatois. Liquid detergent for toilet purposes.* May 28.
„ 12,757. MacDonald. Means for mixing liquids, especially "ley" with cotton oil. June 1.
„ 12,894. Esuman-Gwira. Machine for extracting oil from nuts. June 2.
„ 13,233. Premier Oil Extracting Mills, Ltd., and Caley. Apparatus for extracting oil from seeds, &c., by means of solvents. June 8.
C.S.] 25,425 (1905). Burley and Burley. Manufacture of soap. June 13.
„ 3132 (1906). Pryor (Chem. Fabr. von Heyden A.-G.). Manufacture of iodine fats. June 7.
„ 4481 (1906). Lanza and Gamna. Extraction of olein and stearine from fatty acids. June 13.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(*A.*)—PIGMENTS, PAINTS.

[A.] 13,301. Adam. Carbon recovery plant for the manufacture of lamp black and the like. June 9.

(*B.*)—RESINS, VARNISHES.

[A.] 12,885. Groppler. Method of obtaining copal. June 2.
[C.S.] 20,888 (1905). Godfrey, and Linoleum Manufacturing Co. Manufacture of linoleum. June 20.
„ 2344 (1906). Holtkott. Rolling or pressing inlaid linoleum. June 7.
„ 2436 (1906). Marks (Holtkott). Manipulation of granular linoleum mass and the like. June 7.
„ 3788 (1906). Baringer. Process for rendering copal, manila, sandarach, &c., insoluble in oil. June 20.

(*C.*)—INDIA-RUBBER.

[A.] 12,525. Boult (Köneman). Recovery of rubber from rubber waste.* May 29.
„ 12,526. Boult (Köneman). Recovery of rubber from rubber waste.* May 29.
„ 12,527. Boult (Köneman). Treatment of rubber and rubber waste.* May 29.
„ 13,290. Spencer and Romock. Treatment of india-rubber. June 8.
„ 13,493. Hopkinson and Midgley. Vulcanisation of rubber goods.* June 12.
„ 13,513. Carr. Substitute for india-rubber or gutta-percha. June 13.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

[A.] 13,621. Carter. Tan pits or apparatus for tanning leather. June 14.
[C.S.] 17,536 (1905). Forster. Machinery for use in the manufacture of leather. June 20.
„ 4570 (1906). Sadikoff. Manufacture of glue. June 7.

XV.—MANURES, ETC.

[C.S.] 6429 (1906). Chisolm. Fertilisers. June 7.

XVI.—SUGAR, STARCH, GUM, ETC.

[A.] 12,950. Wagner. Process of manufacturing anhydrous grape-sugar from corn and analogous farinaceous materials.* June 2.
„ 13,217. Barbet. *See under* XVII.

„ 16,177 (1905). Clark (Amer. Water Purifying Co,). Distilling water by the multiple effect system and apparatus therefor. June 7.

„ 5908 (1906). Kremer, and Ges. f. Abwässerklärung. Separation of solid matters from sewage. June 20.

XIX.—PAPER, PASTEBOARD, Etc.

[A.] 12,849. Dickson and James. Manufacture of celluloid. June 1.

„ 12,920. Cochran. Production of cellulose.* June 2.

[A.] 12,936. Mestrallet. Manufacture of non-inflammable celluloid. June 2.

[C.S.] 20,220 (1905). Hanitzsch. Devices for spraying fluid on the surface of paper, fabrics, or the like. June 20.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

[A.] 12,630. Ellis (Chem. Fabr. von Heyden A.-G.) Manufacture of isobornyl esters.* May 31.

„ 13,054. Dreyfus, and The Clayton Aniline Co., Ltd. Manufacture of aromatic sulphinic acids. June 5.

„ 13,055. Dreyfus, and The Clayton Aniline Co., Ltd. Separation of sulphinic acids from solutions, and obtaining them in the form of stable compounds. June 5.

„ 13,056. Dreyfus, and The Clayton Aniline Co., Ltd. Manufacture of sulphonic chlorides, bromides, and amides. June 5.

„ 13,188. De Laire. Manufacture of products by condensing phenol alcohols with other organic compounds.* June 7.

„ 13,401. Newton (Bayer und Co.). Production of new pharmaceutical compounds. June 11.

[C.S.] 21,280 (1905). Ellis (Merck). *See under* VII.

„ 22,094 (1905). Lidholm. Manufacture of compounds of acetylene and chlorine. June 13.

„ 25,571 (1905). Newton (Bayer und Co.). Manufacture of new pharmaceutical preparations. June 7.

„ 10,999 (1906). Chem. Fabr. von Heyden A.-G. Manufacture of isobornyl esters. June 22.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[A.] 13,561. Burnett. Manufacture of iso- or orthochromatic plates. June 13.

[C.S.] 17,007 (1905). Manly. Photographic printing. June 7.

„ 24,875 (1905). Krebs. Flash lights for photographic purposes. June 13.

XXII.—EXPLOSIVES, MATCHES, Etc.

[A.] 12,716. Reschke. Manufacture of safety explosives.* May 31.

[C.S.] 16,514 (1905). Macnab, and Ammonal Explosives, Ltd. Explosives. June 7.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

[C.S.] 1841 (1906). Schatz. Automatic apparatus for analysing gas. June 13.

Official Notice.

ANNUAL GENERAL MEETING.

The Annual General Meeting will be held in Manchester, on Wednesday, July 11th next and following days. A programme and request form accompanied the May 31st issue of the Journal, and the member's ticket accompanied the June 15th number.

In accordance with the provisions of Rule 18 of the By-Laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council (see Journal for April 30th, p. 341) will retire from their respective offices at the forthcoming Annual Meeting.

Mr. Eustace Carey has been nominated to the office of President under Rule 8; Dr. E. G. Love, Mr. A. Gordon Salamon, and Mr. Chas. Wightman have been nominated Vice-Presidents under Rule 8; and Dr. E. Divers, F.R.S., has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Dr. F. J. Smale, Mr. Thos. Tyrer, Sir Thos. Wardle, and Mr. R. C. Woodcock have been nominated, under Rule 18, to fill four vacancies among the Ordinary Members of Council. No ballot will be required.

ALTERATION OF BY-LAWS.

With a view to facilitate the voting of members residing abroad, notice is hereby given, in accordance with Rule 38 of the By-laws, that the Council will propose to the forthcoming Annual General Meeting the amendment of the Society's By-laws as follows:—

1. Rule 18. (*a*) That the words "At least two months before the date of each Annual General Meeting," in the first and second lines thereof, be replaced by the words, "In the second issue of the Society's Journal for the month of April in each year."

(*b*) That the words "date of that meeting," in the fourth line thereof, be replaced by the words "Annual Meeting next ensuing."

(*c*) That the words "At least one month before the date of;" in the sixth line from the end thereof, be replaced by the words "not later than the last day of May prior to."

(*d*) That the words "to the election to take place at which it refers" in the fifth line from the end thereof, be replaced by the words "at which the election to which the nomination refers is to take place."

2. Rule 19.—That the words "at least five days before the commencement of the said meeting," in the two last lines thereof, be replaced by the words, "in the second issue of the Society's Journal for the month of May."

STATEMENT OF REVENUE AND EXPENDITURE FOR THE YEAR 1905.

(Made up to the 12th May, 1906.)

We have compared the above statement with the vouchers, counterfoils of the receipts issued and other records, and are of opinion it correctly exhibits the cash transactions of the Society for the year 1905. The amounts of the Metropolitan 3 per cent. Consolidated, 3 per cent. New Zealand and 3 per cent. New South Wales Stocks have been confirmed by the Chief Accountant to the Bank of England. Certificates for the remaining investments have been inspected and the Bank Balances have been certified to us by the Bankers.

23, St. Swithin's Lane, London, E.C.

J. M. C. PATON IN THE CHAIR.

YEAST AS A BY-PRODUCT.

BY FRANK E. LOTT AND C. G. MATTHEWS.

(*Abstract.*)

Only in recent years has brewery yeast been regarded as available for purposes other than "pitching" or continuing yeast either in breweries, or distilleries at home and abroad. Now, however, there are not a few industrial uses to which this valuable substance—yeast—is put.

A large and increasing quantity of pressed yeast is now being used for the preparation of patent foodstuffs.

Nearly twenty years ago Mr. Cornelius O'Sullivan pointed out the nutritive value of yeast extract. In 1895 Wahl and Henius, of Chicago, patented a process for making "Bouillon Stock" from yeast, which has been a commercial success in America. In 1897 Goodfellow took out an English patent a few months before Mr. C. O'Sullivan himself patented what he had produced many years before, and both these articles have been before the public and consumed in quantity.

Another similar preparation called Vejos was largely advertised as superior to the majority of meat extracts.

In Germany a similar preparation named Sitogen was produced, and probably not a few others of the same type. More recently the "Marmite" Company prepared, and

Mixed with gypsum or lime, yeast has also been used in the preparation of fertilisers, some of which have been patented. Among these may be mentioned "Plasmite,"

	Farm manure.	Guano.	Protorex.	Triterfex.	M. and L. yeast preparation.	Yeast.
Moisture	75	16	34	26	16·2	50

	100	100	100	100	100·0	100

are now manufacturing from yeast the food extract sold under that name.

A comparison of the compositions of some of the patented preparations is shown in the following table:—

"Protorex," and "Trifertex." The authors have also prepared a yeast manure "M. and L. Yeast Preparation," and the general composition of such fertilisers is illustrated in the above table.

Meat Extracts and Yeast Preparations.

An interesting comparison may be instituted between the composition of yeast and that of fungi, taking the mushroom *Agaricus campestris* as a type of the latter in an edible form.

In the following table the composition is returned in terms of dry substance:—

Mushroom and yeast.

	Mushroom *Agar. compestris*	Yeast Nägeli and Löwe analysis.

Extractive matter, carbohydrates (including cellulose) fat	48·7	46·0
Mineral matter	5·2	7·0
	100·0	100·0

Pressed yeast has also been employed for the preparation of cattle foods by admixture with (*a*) dried grains, (*b*) dried grains and spent hops, (*c*) malt culms, ground cereals, &c. The composition of two such articles, compared with that of other well-known cattle foods, is shown in the next table:—

London Section.

Meeting held at Burlington House on Monday, May 21st, 1906.

MR. A. G. SALAMON IN THE CHAIR.

THE ELECTRO-CHEMICAL PROBLEM OF THE FIXATION OF NITROGEN.

PROF. PHILIPPE A. GUYE.

English science has contributed largely to the solution of the electro-chemical problem of nitrogen. Without going back as far as Cavendish's memorable experiments on the transformation of nitrogen into nitrous vapours, we will restrict ourselves to modern researches; it will be enough for me to mention the name of Sir William Crookes, whose experiments of 1893 and whose suggestive address as President of the British Association in 1898 are still present in your minds. Furthermore, there are the experiments of Lord Rayleigh (1897) on the com-

Ordinary and patent cattle foods (in round figures).

bustion of nitrogen. And lastly, this problem has been recently treated in a particularly competent way before scientific circles by Prof. Silvanus Thompson and before the general public opinion of your country by my friend, Sir William Ramsay.

I have followed very closely the development of the large Swiss electro-chemical enterprises which utilise hydro-electric power. Moreover, for some years past, in connection with the "Société d'Etudes Electrochimiques à Genève," I too have been co-operating in researches on the fixation of nitrogen on a semi-industrial scale. Under these circumstances, I hope to be able to secure your attention to special points which have stimulated the study of this interesting problem in the electro-chemical circles of our country.

Before entering on my subject, I have to ask your indulgence in frequently bringing before you numerical tables and data. It is, however, the only way of emphasising the fundamental points of this important question.

I.—Importance of the Problem.

The part played by nitrogenous bodies in economical problems has been so frequently discussed during recent years, that it is unnecessary for me to describe it at length. Certain figures, taken from recent statistics, will suffice as a *résumé* of the most important economical data which dominate its whole study.

The two principal sources of nitrogenous matter of which use is made by civilised nations are nitrate of soda from Chili, and ammonium sulphate.

In 1905, the entire consumption of Chili nitrate was 1,567,000 tons; while that of 1896 was 1,060,000 tons. Of these 1,567,000 tons, we can reckon about 300,000 tons as having been utilised in chemical industry (80,000 to 100,000 tons in the United States and the rest in Europe).

The two principal chemical uses in Europe are: (1) the manufacture of nitrites; and (2) the manufacture of pure nitric acid for explosives, colours, &c.

The use of nitrate of soda as manure is represented by the balance, approximately 1,267,000 tons for 1905; this consumption is rapidly increasing, especially since a commencement has been made in the direction of applying nitrogenous manures to the culture of corn in the United States. Recent calculations by M. Vergara, which have taken into consideration the increase in the consumption of the last few years, indicate the year 1923 as the date when the Chili beds will be exhausted.

This date will be still nearer if we accept the statement made by Sir William Crookes, who estimates that the quantity of nitrate necessary to meet the yearly increasing needs of the "wheat eaters" will be more than 12,000,000 tons after 30 years or so.

Although not quite so considerable, the consumption of ammonium sulphate is by no means less important; it is impossible, however, to obtain statistics for this product as definite as for nitrate, on which duty is paid at the Chili ports of embarkation and on arrival at European and American ports; nevertheless, those most competent to form an opinion, compute that the entire production of ammonium sulphate in 1905 reached at least 500,000 tons (others, however, reckon it as high as 600,000 tons). This quantity is distributed approximately in the following proportions:—

220,000 to 250,000 in Great Britain.
100,000 to 120,000 in Germany.(1)
70,000 to 80,000 in other European countries.
50,000 to 60,000 in America.(2)

The larger part is utilised for agriculture, chemical industry using only 10 to 15 per cent. of the total amount produced. The European consumption would not exceed 350,000 tons.(3)

A large fraction of this product, namely that manufactured in Great Britain, is exported outside Europe, particularly to the East.

This sulphate of ammonia is derived exclusively from gas and coke works. Three years ago it was estimated that the recuperation of ammonia was only practised in about half of the entire number of coke ovens. Since then, there has been a tendency for it to become more general. It will be enough to add that only 10 to 15 per cent. at most of the nitrogen contained in the coal is obtained in the form of ammonia.

At the present rate the production of sulphate of ammonia is, however, insufficient to meet the increasing needs for nitrogen which we may expect in the future.

As regards the commercial value of the nitrogen contained in Chili saltpetre and ammonium sulphate, compared with that of the nitrogen in nitric acid, it may be expressed in the following figures which are based on the market of Great Britain for 1905:—

Product.	Value.	Value of 1 kilo. N.
Chili nitrate, containing 16·5 per cent. N	10*s.* 4½*d.* per cwt.	1*s.* 3*d.* = fr. 1.55
Sulphate of ammonia, containing 21·2 per cent N.	£12 10*s.* per ton	1*s.* 2½*d.* = fr. 1.45
Nitric acid, containing 22·2 per cent. N.	£2 per 100 kilos.*	1*s.* 7½*d.* = fr. 2.25

* Corresponding to 50 fr. per 100 kilos of acid of 100 per cent. HNO_3, a price realised in a great number of factories. This price is a little lower in Germany.

The nitrogen contained in nitric acid has a higher value than that contained in sulphate of ammonia. This can easily be understood, seeing that the expenses incurred in industrial operations for transforming the nitrate into nitric acid must be covered. As to the difference between the nitrogen of the nitrate and that of ammonia, it may be explained by the fact that for the same weight of nitrogen, manures containing nitrate give for most agricultural purposes, and especially for cereals, slightly superior results to those obtained with ammonium sulphate manures. A few years ago a superiority of 10 to 20 per cent. was attributed to the nitrogen of the nitrate over that of the ammonia salt. The difference in price is now slightly less.

Having sketched the general position, it still remains for us to examine how far electro-chemical industry will contribute to equalise the insufficiency of nitrogenous bodies which is to be expected in the near future.

The electro-chemical processes which have been proposed for fixing atmospheric nitrogen are at the present moment very numerous. Most of them have as yet only been studied very summarily; several Reviews have published detailed *resumés* on this subject, of which the following may be more especially alluded to:—Electrochemische Zeitschrift, 1905; Revue générale de chimie pure et appliquée (1906); Moniteur de Quesneville, 1906. We will confine our attention to methods which have received industrial application, in order to be able to throw light on the principal economical factors on which final success depends. The number of these methods at the present day is two: the first produces calcium cyanamide ("Kalkstickstoff" or "chaux azotée"), the other nitric acid and nitrates.

II.—Calcium Cyanamide.

General considerations.—In the course of their researches on the cyanides, Drs. Frank and Caro observed that barium carbide, BaC_2, heated to a high temperature, combines nearly quantitatively with nitrogen to form barium cyanide.(4)

$$BaC_2 + N_2 = Ba(CN)_2.$$

When they tried to apply this reaction to calcium carbide, they were surprised to find that the quantity of cyanide formed was much less than the theoretical amount. Further study revealed the fact that the reaction is different from that which occurs in the case of barium carbide and that in the case of calcium carbide, it is represented by the equation:—

$$CaC_2 + N_2 = CaCN_2 + C.$$

The carbide gives off half of its carbon and changes, not into cyanide, but into calcium cyanamide. This body can be considered as a derivative of ammonia (cyanamide):—

NH_3	$NH_2—CN$	$Ca=N—CN$
ammonia	cyanamide	calcium cyanamide.

When cyanamide is heated with water under pressure, ammonia is set free according to the reaction:—

$$CaCN_2 + 3H_2O = CaCO_3 + 2NH_3.$$

When distributed on the ground the same reaction goes on more or less slowly, and it is therefore easily understood that cyanamide has given very interesting results when used directly as a fertiliser.

Theoretically, the mixture of calcium cyanamide and carbon produced by the reaction given above should contain about 30 per cent. of nitrogen. As a matter of fact the content of nitrogen in the raw calcium cyanamide is less than this amount, either on account of impurities in the calcium carbide or of the changes which it undergoes during the process of transformation. According to the communications of Dr. Frank, the content of nitrogen varies from 14 to 20 per cent. The product of recent manufacture is stated to contain about 20 per cent.(5) From this it will be seen that this amount approaches that of sulphate of ammonia.

The economical future of calcium cyanamide is clearly dependent on its cost price. According to the manner of manufacture this cost price itself depends—

1. On the cost price of calcium carbide;
2. On the cost price of nitrogen;
3. On the cost of transforming the carbide into cyanamide.

Let us examine these three points separately.(6)

Calcium carbide.—In 1902, Vogel estimated the cost price of carbide per ton, without packing, as being about 250 frs. (£10). This price has since then remarkably diminished. This statement can be justified in the following manner:—

Cost price of calcium carbide (without packing):

	frs.
1000 kilos. lime, at 15 frs. per ton	15
700 kilos. coke (retort-coke), at 25 frs. per ton	17.50
20 kilos. electrodes, at 35 frs. per 100 kilos.	7
	39.50
Electric power (1 kilowatt-year) at 50 frs. gives 2.1 tons	23.80
Small expenses:—wages (8 frs.); mechanical power for accessory work(7) (transport, grinding) (30 frs.)	38
General expenses	22
Cost price at the factory	123.30
	or £4 18*s.* 8*d.*

To this sum of 123.30 frs. must be added the depreciation of the plant and interest on capital, both extremely changeable elements; certain factories have had serious technical difficulties when commencing to work, while in others, the price of the hydro-electric installations much exceeded what had been foreseen. It is difficult to give *a priori* a general estimate. On the other hand, it is clear that capital actually invested in these undertakings (if we take into account the reductions of the original nominal capital of the companies) is at the present moment (in the larger works) about 200,000 frs. per 1000 kilowatts, which corresponds approximately to 100 frs. per ton-year on the finished product, of which 25 frs. represents working expenses.

Taking into account a depreciation of 8 per cent. on the plant (75 frs.) and an interest of 5 per cent. on the total capital invested (100 frs.) we have to add to the above sum of ..... frs. 123.30

For depreciation	frs. 6	
For interest on the capital	frs. 5	
		— frs. 11
The net price is therefore	frs.	134.30
		or £5 6*s.* 5½*d.*

This price of 134.30 frs. per ton carbide seems to me to be at the present day the minimum realised cost price, especially if we take into consideration the many industrial risks which are practically unavoidable. According to information which I have received, the estimate has only been realised in Europe in a single works exceptionally well placed in every respect. Only works in Norway can perhaps realise slightly better conditions. It is exceeded to a very large extent on the other hand in the majority of works.

Giving full consideration to the average conditions in Europe, it will be wise to consider the cost price as about from 140—150 frs. in the best situated works, rising to 180 or 185 frs. (185 frs. = £7 6*s.* 7½*d.*) in those placed in less favourable circumstances or whose annual production is not so great.(8)

Cost price of nitrogen.—It is still difficult to give an exact valuation of the cost price of atmospheric nitrogen obtained by the liquefaction and distillation of air. The calculations published on this subject are all based on installations of considerable size and greatly exceeding those which one might expect for a long time to come in the industrial manufacture of calcium cyanamide. In these large installations the cost price would be only a few tenths of a penny per cubic metre or kilogramme of nitrogen. For the relatively restricted production which we are discussing now, it would be wise to estimate the nitrogen at at least 10 centimes, or 1*d.*, per kilo.(9)

Cost price of calcium cyanamide.—No precise information has yet been published on this subject. It is possible, however, to make a first estimate which ought not to be far from facts, based on the following considerations:—

The raw material being calcium carbide, the first thing to take into account is the extreme limits of the price of this product, *viz.*, 140 frs. per ton for large scale factories and 185 frs. per ton for the average European factories. We need not discuss works at which the price would exceed 185 frs.

The cost price of a ton of calcium cyanamide containing 20 per cent. N = carbide at:—

	140 Frs. £5 11*s.* 0*d.*	185 Frs. £7 6*s.* 7½*d.*
1 ton carbide, containing 80 per cent. CaC_2 (*)	140	185
200 kilos. nitrogen	20	20
Manufacture, pulverisation of carbide, charge and discharge of retorts, heating retorts	20	20
Necessary repairs of mills, retorts, liquefying machines	25	25
General expenses	10	10
Packing	20	20
Transport (†)	20	20
Depreciation and interest on capital invested	15	15
Cost price per ton	270 £10 14*s.* 0*d.*	315 £12 11*s.* 2½*d.*
The price of 1 kilo. nitrogen amounts to	frs. 1·35 1*s.* 2*d.*	1·57 1*s.* 3½*d.*

(*) By the addition of certain salts, such as calcium chloride only 800 kilos. carbide would be consumed; but the value of these salts would have to be added, from which we can calculate the average cost of 1 ton.

(†) The transport expenses are calculated for factories working on a small scale. For factories working on a large scale, we would have to take into account that the area supplied would be much larger and the expenses of carriage would be proportionately higher.

At first sight, the price of a kilogramme of nitrogen amounts approximately to the same as that of ammoniacal nitrogen or that of nitrate nitrogen.

But in order to make an exact comparison we must also take into account the coefficient of the agricultural utilisation.

According to the different experiments the value is not yet determined with great accuracy; it seems to depend on the nature of the body and on the manner of utilising the calcium cyanamide as manure. The figures given are between 0·64 and 0·95, Chili nitrate being taken as unity. Adopting, for instance, the average 0·85, it will be seen that the kilogramme of nitrogen, with carbide at 185 frs. per ton, is already more expensive than the nitrogen of ammonium sulphate; in this case, the manufacture of calcium cyanamide appears to be industrially possible only with carbide at 140 frs. per ton. At this price it is evident that the carbide works have every interest in using for this purpose only the excess they are unable to sell for the production of acetylene, carbide intended for lighting purposes giving them a

higher profit; at the present time, this product is taken on the average at 200 frs. per ton (without packing). It realises even higher prices in France and Italy.

III.—Electro-chemical Nitric Acid.

General considerations.—The second way of fixing atmospheric nitrogen has, as its starting point, an observation of Priestley, confirmed and amplified by Cavendish (1784), who found that nitrogen and oxygen combine slowly under the action of electric discharges to form oxides of nitrogen, which then change, by more or less complex chemical processes, into nitric acid, nitrous acid, or nitrates and nitrites. The fundamental reaction is therefore, according to the happy expression of Sir William Crookes, a real "combustion" of nitrogen in oxygen. But we may add, in order to be precise, that this combustion is "slow and lazy," since it goes on only as long as the electrical energy continues to act and since it also stops as soon as the content of nitrogen oxides in the gas has attained a certain limiting value.

For about 10 years attempts have been made to devise a process of manufacture of nitric acid on this basis. I do not intend to describe in detail the various methods which have been suggested, but will summarise the general conclusions which may be drawn from these researches. I should state, however, that the first attempt of this kind, made in Switzerland, was due to Aloys Naville in 1893, who proposed to me shortly afterward to study this problem in collaboration with him and Prof. C. Eug. Guye.

The principal results of this collaboration have been condensed in patents taken out in 1895 and 1896, in which we formulated for the first time a principle which appears to us fundamental; it is *that the yield is notably increased when the electrodes are placed in a narrow part of the chamber, in which the reaction takes place, in order to submit the whole of the gas to the action of the electric energy and to draw off as rapidly as possible the gases which have been subjected to this action.*

The results of this work were taken up in 1896 by the "Société d'Etudes Electrochimiques," in Geneva, and tests have been carried out continually since that time on a moderately large scale. Other experiments in the same direction have been made by the Atmospheric Products Co., at Niagara Falls (Bradley-Lovejoy method), the "Groupe d'Initiative," in Freiburg, Switzerland (method of Kowalski), and the Hydro-elektrisk Kvælstofaktieselskab, in Norway (method of Eyde and Birkeland).

Recently we have heard about projected plants which will be worked by Pauling in Austria, and by the "Badische Anilin und Soda Fabrik" in Germany.

Independently of these developments, which have a more or less industrial character, very interesting laboratory researches have been made by Crookes (1897), Lord Rayleigh (1897), McDougal and Howles (1900), Muthmann and Hofer (1903), von Lepel (1903), Nernst (1904), and Scheuer (1905).

At the beginning of these researches contradictory results were often announced. It appeared as though the effects produced would be different, according to whether the arc is produced by alternating or direct current, or whether the arc is elongated or shortened. Some have recommended currents of small intensity, others currents of large intensity. The presence of water vapour in the air has sometimes been claimed to prove favourable, sometimes unfavourable. Even the form of the electrodes appeared to play a more or less important rôle. To sum up, the combustion of nitrogen at the temperature of the electric arc appeared to be subject to very peculiar, capricious, and mysterious laws, and seemed to depend on new and strange factors.

All the factors mentioned above are now known to be secondary and accessory. The detailed study of the problem has proved that the phenomenon is strictly governed by the fundamental laws of chemical dynamics.

This method of looking at the problem has not only the advantage of simplicity, but it also furnishes valuable indications of the possibilities which may be realised, and so far there exists good agreement between theory and experimental results. The following discussion is based upon this point of view:—

Chemical Phenomena Due to an Arc in Air.

The chemical phenomena which occur when an electric arc passes through atmospheric air, may be suitably discussed under three different headings: First, the initial reaction; second, the influence of temperature; third, the reverse reaction.

Initial reaction.—At the high temperature of the electric arc in air, the molecules of nitrogen and oxygen dissociate into their atoms, which is followed by the combination of these atoms to form nitric oxide. The reactions are, therefore,

$$N_2 = 2N \text{ and } O_2 = 2O$$

then

$$2N + 2O = 2NO$$

Like most chemical reactions, this reaction is incomplete. That means that for a given temperature and for given initial conditions of pressure, composition, &c., the reaction stops when the content of nitric oxide reaches a certain value.

The underlying reason of the stoppage of the reaction is its reversibility. The stoppage will take place when the above reaction—the combination of the N and O atoms to nitric oxide—and the reverse reaction—the dissociation of the nitric oxide into N and O atoms—hold each other in equilibrium; *i.e.*, when in the same time the same number of NO molecules are formed by one reaction as are dissociated by the opposite reaction. The reversibility is expressed by the equation—

$$\tfrac{1}{2}N_2 + \tfrac{1}{2}O_2 \rightleftarrows NO$$

It is difficult to measure the content of the nitric oxide gas in the state of equilibrium, since in the presence of an excess of oxygen (which is always the case in these experiments) the nitric oxide changes rapidly into peroxide at temperatures below 500° or 600° C.

$$NO + O = NO_2{}^{(10)}$$

The results of analysis are, therefore, generally given in the form of NO_2. But this does not modify the preceding conclusions.

Effect of temperature.—The reaction proceeds the further the higher the temperature, other things being equal. The following figures were found by Nernst and controlled by calculation on the basis of the law of mass action:—

Absolute Temp.	Per cent. by volume of NO, observed.	Per cent. by volume of NO, calculated.
° C.	per cent.	per cent.
1811	0·37	0·37
2033	0·64	0·67
2195	0·97	0·98
3200	5·0	4·4

The time in which the limit of NO gas is formed, *i.e.*, the time in which the condition of equilibrium is reached at a certain temperature, is the shorter the higher the temperature. We give some figures of the same author indicating the time during which the reaction is half completed; *i.e.*, the time in which half the above limiting values are reached. It is 100·0″ at 1540° and 3·5″ at 1737°.

It follows that a double advantage is derived for the combustion of nitrogen from the use of as high a temperature as possible. First, the content of nitric oxide is increased, and, second, the transformation occurs more rapidly.

It is true that these advantages are partly compensated by the fact that considerably more heat energy will be required at an elevated temperature, since the electric arc has to furnish the calories, raising to the desired temperature not only the nitrogen and oxygen which combine, but also the excess of the two gases which do not combine. A careful calculation shows, however, that the larger expenditure of energy required at the higher temperature represents an expense which is more than counterbalanced by the better efficiency obtained thereby. The use of a high temperature is therefore an advantage.

Prof. F. Haber[11] gives the following figures:

1 kilowatt-year (of 365 days of 24 hours each) can theoretically yield the following maximum amounts of nitric acid by combustion of atmospheric nitrogen:

1850 kilos. HNO_3 at 4200° C.
819 kilos. HNO_3 at 3200° C.

A decrease of the temperature by 1000° C. results, therefore, in this case in a reduction of the efficiency by more than 50 per cent.

Reverse reaction.—The formation of nitric oxide at the high temperature is followed by the dissociation of the oxide into nitrogen and oxygen during the period of cooling.

This is a necessary consequence of the laws of chemical dynamics applied to reversible reactions. If, for instance, the fundamental reaction

$$\tfrac{1}{2}N_2 + \tfrac{1}{2}O_2 \rightleftarrows NO$$

is carried out at a temperature of 3200°, whereby the limit of formation of nitric oxide in volume is 5 per cent. (Nernst's figure), and if the gas mixture is then cooled very slowly to 2200° and equilibrium is again established at this temperature, the volume of the NO will be reduced to 1 per cent. During the slow reduction of the temperature by 1000°, therefore, 80 per cent. of the NO which was produced before at 3200° is lost. This is the phenomenon of the reverse reaction.

We have already seen that by raising the temperature equilibrium establishes itself with greater speed at higher than at lower temperatures. In the same way, when the temperature is diminished, the reverse reaction proceeds more rapidly at higher temperatures than at lower temperatures. This is also a consequence of the general phenomenon of reversibility.

It follows that the most dangerous temperatures—those in which the reverse reaction during cooling will undo what has been performed before—are higher temperatures, near the temperature of the primary reaction. From this results the necessity of cooling the gas mixture as suddenly as possible from the temperature of the arc, in order to bring it in the shortest possible time to temperatures at which the velocity of the reverse reaction is practically zero. In the case of combustion of nitrogen this condition is realised more easily, for the reason that below 600° NO combines gradually with the excess of oxygen to form nitrous vapours which escape the reverse reaction.

In practice, the tendency has been to obtain this result first by rapidly sweeping the gases out of the region of action of the arc, while more recently use has been made of electrical or mechanical devices by which the arcs were successively lighted and interrupted several thousand times per second, or the arc has been forced to play in different regions of the space. In all these cases the gas mixture which has been brought instantaneously by the arc to a very high temperature is also cooled instantaneously in the mass of surrounding cold air, and the effects of the reverse reaction are, if not suppressed, at least considerably diminished.

To sum up, the fundamental considerations which govern the combustion of atmospheric nitrogen are the following: First, it is necessary to work at a high temperature in order to increase the efficiency and the velocity of the reaction; second, to cool the gas instantaneously in order to avoid the reverse reaction.

It is at once evident that it is rather difficult to realise simultaneously these two conditions in practice. According to whether the experimenters have satisfied more or less one or the other condition, the results have apparently been contradictory. This explains the very peculiar results to which we referred above.

The gases obtained in this way contain some 1 or 2 per cent. by volume of nitric oxide when they pass out of the arc chamber, and must then be treated in order to transform the nitric oxide gas into nitric acid or into nitrates and nitrites. These operations are more of chemical than of electro-chemical interest, and it will be sufficient to indicate their principle, although the practical operation involves certain difficulties. It is, indeed, necessary to handle a considerable dead weight of inert or indifferent gases. By cooling the nitric oxide gas, NO is transformed into N_2O_3 and N_2O_4 as soon as the temperature falls below 500° or 600°. Proper reactions with water, or with alkaline solutions (caustic soda, lime water, &c.), give either dilute nitric acid or nitrates or a mixture of nitrates and nitrites.

We may finally call attention to a characteristic feature common to all the methods which have been studied.

Whatever may be the method which is adopted, whether with direct current or with alternating current, or with rapid electric oscillations in air in motion, or whether the electric discharges are displaced in space, the arc, in order to be lighted, requires a higher voltage than that which is sufficient to maintain it in a state of stability after it has once been established. It is, therefore, necessary to install between the source of electrical energy and the arc chamber either a considerable resistance with direct current or one or several induction coils with alternating currents or oscillatory discharges. From a practical point of view, this means that in the arc only a fraction of the nominal capacity of the dynamo can be utilised. With alternating currents, for example, there will always be a considerable phase difference, measured by a power factor which has often a rather unfavourable value. Estimates of installations must take this point into account, since it amounts to an increase in the cost of dynamos, and, therefore, in the cost of electrical energy.

The extended and expensive researches of recent years have, therefore, very greatly simplified the understanding of this problem which formerly was so mysterious. It may be interesting to state what has been accomplished in practice.

In respect of the cost, the sources of information are much less numerous than in those which concern calcium carbide and, consequently, cyanamide. The problem of the fixation of nitrogen as nitric acid presents many different features. Nevertheless, several important publications relative to experiments carried out in Norway, on a very considerable scale, furnish very interesting information as regards fixing the cost price of electro-chemical nitric nitrogen.

This cost price appears to depend in the first place upon factors easy enough to determine. In reality it is simply a question of provoking a partial oxidation of the atmospheric nitrogen by submitting the air to the action of electric energy and then combining the oxides of nitrogen thus formed with water and oxygen in order to obtain them in the form of nitric acid; by neutralisation with lime we could get, if wanted, calcium nitrate; in Norway, they use an excess of lime and produce a basic calcium nitrate containing about 75 per cent. $(NO_3)_2Ca$ (12 to 14 per cent. N), with about 2 per cent. CaO in excess.

It is rare to find a chemical process so simple; the only expenses to be considered are, on the one hand, electric power and, on the other hand, current manufacturing expenses. Finally—an occurrence practically unique in the industrial world—the cost of the raw material is zero, if it is simply a question of preparing nitric acid, and is almost negligible when nitrate of calcium is produced.

Let us examine these different elements one by one.

Electric energy.—The most favourable results as yet published indicate a production of 900 kilos. HNO_3 per kilowatt-year, measured at the arcs (Eyde and Birkland). (All the yields are calculated as nitric acid of 100 per cent. HNO_3.) Prof. Haber has calculated a theoretical yield of 1800 kilos. per kilowatt-year. According to Prof. Witt the quantity of nitric acid obtained at Notoden during last summer amounted to between 500 and 600 kilos. per kilowatt-year. In one of their patents the Badische Anilin und Soda Fabrik mentions that they obtained 650 kilos.

At the "Société d'Etudes Electrochimiques" at Geneva, with extremely simple and cheap apparatus, we have obtained a yield of about 400 kilos. of nitric acid.

It seems then that we may take a production of 500 kilos. HNO_3 per kilowatt-year as being a fair average. This production may be greater or less according to the degree of simplicity of the apparatus employed. Without doubt, the yield will be certainly increased in the future; in reality we are only in the introductory stages of this industry.

Recovery of the oxides of nitrogen.—The process of recovery which has been, up to the present, adopted by different experimenters is based on the absorption of these oxides by water. Prof. Witt states that approximately 95 per cent. of the nitrogen oxides thus formed at Notoden are recovered.

In reality the recovery is not so simple as it might appear at first sight; for the chemical mechanism of the fixation of nitrogen oxides by the elements of water is extremely complex.

At Notoden, the products of three furnaces, each 700 h.p. (500 kilowatts), are conducted into a system of two parallel series of five granite towers, each of which has a capacity of 40 cb. m.; in each of the series the last tower is filled with milk of lime in order to retain the poorer gases. The capacity of the system is thus 400 cb. m.; its power of absorption amounts to 3·3 kilos. of HNO_3 per cubic metre in 24 hours. This corresponds approximately to the capacity of production in lead chambers (2 to 4 kilos. per 3 m. of chamber, acid of density 1·5 to 1·6), which is equal to from 2 to 4 kilos. per cubic metre.

As the result of the researches made by the "Société d'Etudes Electrochimiques," it is more advantageous to employ sulphuric acid as absorber; the power of absorption of this latter being in reality much greater than that of water. On the other hand, the methods of absorption by water are capable of considerable improvement.

The "Société" is now engaged in studying certain newly patented processes by which either dilute nitric acid of 50 per cent. HNO_3 is directly produced, or fuming nitric acid containing 96 per cent. HNO_3.

The plant built in Norway, which represent nearly 0·3 cb. m. capacity per kilowatt, seem to be somewhat expensive, especially if we take in consideration all the accessories they demand (tubulated cooling system, extensive canalisations for both gases and liquids, ventilators, pumps, &c.). No actual figures have as yet been published as to the cost of that plant; but their principal dimensions being given, it is not difficult to estimate approximately the cost; it must reach to between 300 to 400 frs. for each kilowatt used in the furnaces. The sum necessary to keep all this material in repair ought to be a considerable fraction of the current expenses.

By the recuperation by means of sulphuric acid, I estimate the capital invested at 200 frs. per kilowatt.

Having established these points, we find that the cost price of a ton of nitric acid is represented by the following figures:—

	frs.
Electric energy at 50 frs. per kilowatt-year for a production of 500 kilos. per year	100
Repairs	40
Wages and general expenses	10
Depreciation and interest on capital at 5 per cent.	55(12)
In francs	205
In £ Sterling	£8 3*s.* 5*d.*

To this price of 205 frs. we must add the expenses of packing and transport; these will be entirely different according to the form in which the product is delivered. This fact allows us to distinguish the two following principal alternatives:—

1. When the nitric acid is transformed into calcium nitrate; in this case there are approximately the following additional expenses:—

	frs.
Lime, 0·45 ton at 15 frs. the ton and handling thereof	15
Packing (air-tight drums)	28
Transport (the same figure as for cyanamide)	20
	63
Expenses of production	205
Price per ton HNO_3 delivered as nitrate of calcium	268
	£10 14*s.* 5*d.*
Cost price of nitrogen per kilogramme in the same form	1.25 or 1*s.*

2. When the nitric acid is delivered direct as acid (in particular as concentrated nitric acid). In this case it would be enough to add to the above-mentioned sum of ..... frs. 205
The expenses of packing and transport .. frs. 50

Price per ton HNO_3 delivered as nitric acid.. frs. 255 or £12 2*s.*
Price per kilogramme nitrogen ..... frs. 1.15 or 11½*d.*

We have already mentioned that the actual value of nitrogen per kilogramme is the following:—

1.55 frs. in Chili nitrate = 1*s.* 3*d.*
2.25 frs. in chemical nitric acid = 1*s.* 7½*d.*

On comparing these figures we may conclude that electro-chemical nitric acid can compete successfully with the last two products. Besides that, the price of electro-chemical nitric nitrogen per kilogramme is practically the same as that of the nitrogen contained in calcium cyanamide prepared from the excess in the manufacture of carbide (1.35 frs.), if we do not take into consideration an agricultural coefficient of the cyanamide.

IV.—Future Prospects.

If we attempt to compare the characteristic features of the two principal methods of electro-chemical fixation of nitrogen, which occupy at the present moment the attention of manufacturers and economists alike, we observe in the first place that the yield per unit of electric energy is superior in the cyanamide process.

Yield in nitrogen per kilowatt-year.—With one kilowatt-year electric power, we obtain 2 tons carbide = 400 kilos. fixed nitrogen.(13) With the same power we obtain 0·5 tons HNO_3 = 111 kilos. fixed nitrogen.

Nevertheless, the cost price per kilogramme of fixed nitrogen is no higher in the electro-chemical nitric acid process (without taking into account an agricultural coefficient for cyanamide):—

Cost price per kilogramme fixed nitrogen.—By the cyanamide process, carbide at 140 frs. a ton = 1.35 frs.; carbide at 185 frs. a ton = 1.58 frs. By the electro-chemical nitric acid process, as basic nitrate of calcium = 1.21 frs.; as nitric acid = 1.15 frs.

Profit per kilowatt installed.

(The capital invested for one kilowatt installed is almost the same for the two processes, that is 200 to 300 frs., or £8 to £12).

With cyanamide.—Nitrogen sold at the price of that of ammonium sulphate: $400 \times (1.45 - 1.35) = 40$ frs. = £1 12*s.*

With nitric acid.—(A) Nitrogen sold at the price of that of Chili nitrate: $111 \times (1.55 - 1.20) = 38.85$ frs. = £1 11*s.* 1½*d.*

(B) Nitrogen sold at the price of that of nitric acid: $111 \times (2.25 - 1.20) = 116.55$ frs. = £4 12*s.* 5½*d.*(14)

The lower price of nitrogen in nitric acid is due to the fact that the yield, although smaller in the last-named process, is greatly compensated for by the extreme simplicity of the operations and also inasmuch as it is unnecessary to take the price of raw materials into account.

If we consider the matter, it is really impossible to imagine more simple operations than the oxidation of atmospheric nitrogen and the subsequent absorption of the oxides of nitrogen formed.

Nitric nitrogen offers in itself several important economical advantages which it is interesting to examine briefly.

To begin with: as regards agricultural needs it is evident that calcium nitrate, closely related as it is to sodium nitrate, has before it almost unlimited prospects which are daily increasing. It is already well known that all nitrates of alkalis or of lime are as good manures as the nitrate of soda.

In the second place, electro-chemical nitric nitrogen has before it an extremely brilliant opening, through its sale in the form of nitric acid, which represents in Europe alone a market of about 200,000 tons. It looks as if it were an economical error in this new industry to supply,

in the first place, nitrate of calcium, as is done in Norway, instead of nitric acid. The nitric acid leaves a greater margin for profit as has already been shown. Our principal efforts ought, therefore, to be concentrated on the manufacture and sale of this acid, which would make it possible for the factories to pay off rapidly the capital invested on the initial plants, at the same time perfecting the technique of the processes. It is all the more to the interest of this industry to follow this branch, since the uses of nitric acid are continually increasing and others are to be expected as soon as its price has sunk lower.

To continue, as regards the future of the two industries, we think that the development ought not to be considered as that of two rivals in the usual sense of the word.

The principal aim in the development of the nitric industry should be that of the production of nitric acid, at the same time with a view to increasing the yield. It will have consequently before it a very large future, in the manufacture of nitrate.

On the other hand, the cyanamide industry is destined, at first, to be linked with the carbide industry; considering the actual cost price of calcium carbide, it will scarcely be possible to develop this industry anywhere but in the neighbourhood of carbide works, possessing favourable economical conditions: and even then it would only employ the excess of carbide not absorbed for lighting purposes. We have already observed that the sale of carbide for lighting is much more remunerative. If all the circumstances are not especially favourable, the building of large carbide factories, destined exclusively for the manufacture of cyanamide, seems to be more or less hazardous; especially if we take into consideration the diminution in price of nitric nitrogen, which can be considered practically certain to take place in the more or less near future. Other considerations, which will be examined a little later, give further weight to this argument. Although limited in this way, I consider that the field for activity still remains very large.

Finally, I should like to add that it is all the more in the interest of these two growing industries not to consider themselves as rivals, for they can benefit by working hand-in-hand with a view to a better utilisation of the atmospheric elements—nitrogen and oxygen—as I have already suggested in my lecture before the *Société Helvétique des Sciences Naturelles*. In the cyanamide industry, the atmospheric oxygen is actually lost; whereas it might be employed with advantage in the manufacture of electro-chemical nitric acid, in which the addition of this gas to the atmosphere constitutes a favourable factor in increasing the yield per unit of electric energy.

Captivating as the prospects are which are open to these two young industries, it may be well to glance at several exterior factors liable to promote or retard their development.

We have just indicated the importance of liquid air in this respect; it is certain that every progress realised in this branch ought to be considered as a factor favourable to the rapid extension of the processes of electro-chemical fixation of nitrogen.

A question not less important concerns the production of electric energy, which is indispensable to the extension of these processes. It is certain that the first nitrogen works will make use of this energy at a low price, furnished as it will be by large hydro-electric stations; however, we must not deceive ourselves and certainly not forget that this source of energy is more limited than is generally realised. The hydraulic forces still available, and at the same time favourably situated, reach in Europe a power of several hundred thousand kilowatts—at most one million. Although it is true that they constitute a reserve sufficient to fix a quantity of nitrogen corresponding to a very large part of the present European consumption of nitrates and ammoniacal salts, still they would not be sufficient to meet the larger consumption which we may consider as a certainty in the near future.

Our attention is therefore attracted to the problem of the economical production of energy by means of motors, employing in some form or other (vapours, poor gases, &c.) coal power. The progress made in this branch during the last 20 years has been so considerable that we may contemplate its future with confidence.

In this respect, the important industrial researches of Dr. L. Mond, seem to me to have indicated the fundamental principles by means of which electric energy will certainly be furnished in the future to the electro-chemical industry in countries which do not possess hydraulic power. These methods, based on the recuperation of nitrogen, are doubly interesting in connection with the subject which is occupying our attention. It is, therefore, indispensable that we should pause here for a few moments, less in order to fix the details with which you are already acquainted, than to emphasise the immense future which awaits these processes: and here let me express my thanks to Dr. Mond and to Mr. Emile Mond, Managing Director of the Power Gas Corporation, to whom I am indebted for several of the following particulars.

Dr. Mond's system consists in producing gas from gas-producers under conditions which permit the recovery in the form of ammonia of the greater part of the nitrogen contained in the fuel and in utilising afterwards this gas in gas engines, which, in their turn, drive dynamos.[15]

In the case of especially powerful producers, moist air is passed through the incandescent coal (up to 2½ tons of water per ton of coal). This operation ought to be conducted at not too high a temperature. After the gases have been scrubbed in appropriate apparatus, from 60 to 70 per cent. of the nitrogen contained in the coal is extracted as ammonia; this represents on the average 40 kilos. of ammonium sulphate per ton of coal.

The system is applicable even to combustibles of very inferior quality.[16] The calorific power of the fuel being approximately 6786 cal., the heating power of the gas would be 77 per cent. of that of the coal.

From the economical point of view, these most remarkable results may be interpreted by one or other of the following possibilities:—

(*a*) Either the combustible gas is reckoned at the ordinary price of general production; in which case the cost price of sulphate of ammonia amounts to £4 per ton (Journal of Gas Lighting, 1903).

(*b*) Or we may deduct the profit arising from the sale of ammonium sulphate from the cost price of the motive power generated by gas engines; a fact which is distinctly in favour of the gas engine.

If we apply the preceding data to the average conditions in Europe for the production of electric energy in power stations producing several thousand h.p. by gas engines, and if we reckon at £14 per electric h.p. the cost of the outfit, the price per electric h.p.-year would amount to about £3 with fuel at 10*s.* a ton.

The industrial Mond-gas plants which have been built in England realise conditions very similar to those which we have just indicated. The price per h.p. (electric) is, I understand, approximately £2 15*s.* a year, with fuel at 7*s.* a ton.

If we apply this last figure to the cost price of electro-chemical nitric acid, as we have already estimated it, the latter would amount to 325 frs. (£13) a ton; in which the fixed nitrogen would be 1.58 frs. = 1*s.* 2*d.* the kilo. This is about the price of the Chili saltpetre nitrogen; it leaves, on the other hand, a very interesting margin for the production of nitric acid.

If we take into consideration the enormous advantages which the chemical industry will gain in manufacturing these products in the neighbourhood of centres of consumption, we shall be able to appreciate without difficulty the very great interest attaching to the development of these methods.

Their importance is still further enhanced by the possibility of producing ammoniacal salts in enormous quantities if we remember that the world's consumption of coal is now not far from one million million tons a year.[17]

It is scarcely necessary to add that this production of ammonia will furnish the electro-chemical nitric acid industry with facilities for producing ammonium nitrate at a low price. This latter, among all the nitrogenous bodies destined for agriculture, is the one which is best adapted to long distance transport, thanks to its high percentage of nitrogen. At the same time it is the nitrogenous fertiliser *par excellence*.

The following table shows the percentage of nitrogen contained in the various nitrogenous bodies under consideration :—

	Nitrogen per cent.
Sodium nitrate	16·5
Ammonium sulphate	21·2
Guano	10—15
Calcium cyanamide	14—20
Calcium nitrate	17·1
Basic calcium nitrate (Norway)	13—14
Nitric acid HNO_3	22·2
Nitric acid of 95 per cent.	21·1
Ammonium nitrate	35·0

Such are, gentlemen, the different prospects of the near future, presented by the problem of the fixation of nitrogen. To what degree and how soon will they be realised ? That is a question difficult to answer. Although the value of the numerous figures which I have given is rather comparative than absolute, it remains an indisputable fact that at the present day this branch is really and effectively open to industrial methods, which will shortly assure the civilised world of a supply of nitrogen which it will no longer be able to extract from the exhausted reserves in Chili.

The principal part of the nitrogen will be derived from the atmosphere : electro-chemistry now being in a condition to fix this precious element. On the other hand, we can foresee that coal also, which has already proved of such importance in our economical development, will not lag behind in this conquest, to which, furthermore, contributions will certainly be made by rational methods of liquefying air and so separating its elements. Final success is, in a word, dependent on the expansion and development of the most modern discoveries of science and of applied chemistry. It is on this final success that the future of the civilised world depends, and I think, gentlemen, that these considerations are sufficiently important to attract and hold the attention of your Society.

I should like to add my cordial thanks to the Society for having given me the opportunity of bringing before them a problem which has occupied my attention for the last 10 years.

(1) M. Frank (Ztschft. für angew. Chem., 1905, p. 836) recently indicated that agricultural needs in Germany absorb 200,000 tons yearly. Prof. Witt gives only 90,000 tons in his report on the Paris Exhibition of 1900.

(2) 40,000 tons according to a recent publication (Electrochemical and Metall. Industry, 1906, p. 121).

(3) These estimates comprise only the consumption of ammonium sulphate. In order to obtain the total consumption of ammonium we must add to these figures the ammoniacal liquors used in the soda factories, which employ the Solvay process. According to Mr. Ernest Solvay (Congress of Berlin, 1905), the entire production in 1902 of soda by the ammonia process reached 1,610,000 tons. This figure ought to be still fairly exact, as shown by a communication for which I am obliged to Mr. Armand Solvay. On the other hand, Mr Schreib states that the minimum loss of ammonia is 0·75 kilos. per 100 kilos. of soda, from which we can deduce an average loss of 1 kilo. In this case the ammonia consumed by the Solvay Soda Works would be 16,100 tons, which corresponds to about 77,000 tons of ammonium sulphate.

(4) This process was patented by Readman and Parker, and is in operation at the works of the Scottish Cyanide Company, at Leven, Fifeshire.

(5) This high percentage of nitrogen is obtained only with calcium carbide of good quality.

(6) In giving the following figures, I have endeavoured to make an estimate which shall not err on the optimistic side. I have preferred to place a somewhat high price on the power and on the raw materials, and to make the conditions as far as possible comparative. If any of my figures require correction in a more favourable sense, I shall be the first to express satisfaction.

(7) In this case the price is restricted to factories working on a large scale ; it reaches a much higher figure for smaller installations.

(8) The chief improvements introduced since 1902 into the manufacture of calcium carbide may be summarised as follows :—
The quantity of raw materials employed (lime and coke) has somewhat diminished ; per ton of carbide, 1100 kilos. of lime and 750 kilos. of coke were then deemed sufficient ; the most important reduction relates to the electrodes. By more rational construction of the furnaces, a saving of 10 to 20 kilos. has been effected in lime and carbon, at least in making fused carbide ; some works have succeeded in making a saving of even more than 20 kilos. On the other hand, the manufacture of electrodes has been centralised more and more in special works, and they are now sold to carbide manufacturers at a price on delivery of 35 to 40 frs., instead of the 50 or 60 usual some years ago.
In the early days of the manufacture of fused carbide (*carbure coulé*) (the manufacture of cakes is being given up), only 3·5 kilos. of 80 per cent. carbide was produced by 24 electric kilowatt-hours. However, by careful supervision, by improvements in furnaces, and especially by the use of greater electric power (500, 1000 and 2000 kilowatts), the yield has been increased to 6 kilos. per 24 kilowatt-hours, or 2·1 tons per kilowatt-year ; it is said that some works obtain even more.
The cost of electric energy must be taken at a very low figure, for the manufacture of carbide has stopped except in works very favourably situated in this respect. Several works in central Europe reckon that their electric power costs not more than 50 per kilowatt-year.

(9) It is necessary to note that a carbide factory of 5000 kilowatts power, able to turn out 10,000 tons carbide a year, and disposing of, for instance, 20 per cent. of its production to transform it into calcium cyanamide, namely, 2000 tons, would consume only 400 tons of nitrogen—in other words, a little more than a ton a day However, in accordance with the calculations published the nitrogen could not be obtained at a price of a few centimes the kilo. unless the daily production reached 40 to 50 tons.

(10) Some authors have assumed that nitrogen peroxide is directly formed But this assumption is untenable in view of the experiments of Richardson, who found that the gas NO_2 dissociates completely into NO and $\frac{1}{2}O_2$ at a temperature between 500° and 600° C , which is much below the temperature of the electric arc.

(11) F. Haber, Thermodynamik technischer Gasreaktionen (München, 1905), page 251.

(12) This is calculated on a capital of 200 frs. per kilowatt. instead of from 300—400 frs., to make allowance for the improvements resulting from the rational recovery by means of sulphuric acid.

(13) Or 280 kilos. if the percentage of nitrogen is only 14 per cent.

(14) This figure is certainly too high : if the production of electro-chemical nitric acid is realised on a large scale, the price of this product will become lower.

(15) The consumption of gas is 66 cb. ft. per B.H.P. hour, *i.e.*, about 71 cb. ft. per electric h.p. hour.

(16) Thus with coal of 62·69 per cent. C and 10·42 per cent. ash, it was possible to convert into gas 57·38 per cent. of C, whereas 5·31 per cent. remained in the ash. The gas so obtained contained (in volume) :—CO, 11 per cent. ; H_2, 29 per cent. ; CH_4, 2 per cent. ; CO_2, 16 per cent. ; N_2, 42 per cent. One ton of the fuel produced 30·59 cb. m. of this gas, saturated with water at 15° C. ; its calorific power was 1317·8 cal. per cb. m.

(17) The recovery of the nitrogen, applied to only one-tenth of this consumption, within the limits of the Mond's process, would give about one million tons nitrogen per annum, *i.e.*, four times about the actual consumption of nitrogenous bodies.

Discussion.

The Chairman read a telegram from Dr. Frank, of Charlottenburg, regretting his inability to be present. He was glad to add, however, that his colleague, Dr. Caro, had specially come to attend the meeting. He also read letters from Lord Rayleigh, P.R.S., and Dr. Ludwig Mond, F.R.S., expressing regret at their inability to be present.

He felt sure that the discussion would be free from bias towards any particular process or patent. They were there to discuss, in its broadest possible aspects, a question of enormous importance, namely, whether or not it was practicable from an industrial point of view to supply nitric acid in a form which could be obtained from the atmosphere, instead of being dependent on Chilian nitrate as they were to-day. Amongst other points raised, the question of the transport of nitric acid appeared to demand consideration, and he would like to hear the views of technologists as to whether or no there were difficulties attending the transport upon such a scale and over great distances of nitric acid of such strength as 1·5 sp. gr. He did not suggest it could not be done. There were questions in connection with transhipment, &c., which should be discussed. With regard to the cyanamide, the author had treated that as a by-product, resulting from the surplus production of carbide, and he had taken the price of the latter without packing at something over £5 a ton. Those might be the conditions obtaining to-day, but many of them would have read of propositions to which practical effect, he understood, was about to be

ven to produce carbide at a very much lower price, id if that proved to be correct, he would suggest that the atement that cyanamide would come out at about the me price as nitrate of soda would require serious modifi- tion. He should also like to hear what such authorities Dr. Voelcker and Dr. Dyer had to say with respect the stability of cyanamide possessed of a definite anurial value at the place where it was used: such ability had, he understood, been questioned. The prices on which the author had based his nitric acid compari- ns appeared to be taken upon the present price of trate of soda, and one would like to know whether, in ew of the suggested competition, in respect of 200,000 ns per annum to commence with, those interested in trate would be content to remain passive, or whether ere was a possibility of a reduction in price, and to hat extent it could go. What was the margin of reduc- on possible in that connection? Even if this process ly effected a serious reduction in nitrate, it must react vourably to the whole community. They would like learn more about the wear and tear of the furnaces hich had been described, and how long they had been at ork on a sufficient scale to make a fair estimate in this rection possible.

After Dr. DIVERS, as President of the Society, had pressed a welcome to the distinguished visitors,

Sir WILLIAM RAMSAY said he wished to make a slight rrection; it was not Cavendish who first discovered e union of nitrogen and oxygen by the spark, but riestley, as Cavendish himself acknowledged. It was ue that neither of those experimenters knew what they ere doing. They were dealing with "phlogisticated" id "dephlogisticated air"; still, the credit was due Priestley for the original discovery, though great progress as made by Cavendish, in his remarkable researches. The hairman suggested that, supposing this new scheme came to force, and calcium carbide could be made at a very w figure in Norway, whether that would not throw so uch on the market that it could not all be taken up for ghting purposes, and that a great deal would be available r the production of cyanamide, or that possibly it would so. But there was a counter consideration.

Calcium carbide gave a very cheap light, and from e country-house point of view, illumination by its use as by far the simplest method if one excluded the oil mp. Now, if the price of calcium carbide were reduced, e consumption would go up enormously, because what ilitated against its use at present was its high price. alcium carbide at its present price when interpreted into gures would represent coal gas at about 8*s.* or 10*s.* r thousand, and that was rather a deterrent for the oprietors of small country houses. He believed, how- er, that if calcium carbide were made cheaper, a great crease in consumption would take place, and that again ould militate against its use in any large proportion r manufacturing calcium cyanamide.

Dr. N. CARO said the Chairman had correctly pointed it that the question whether the processes for the xation of atmospheric nitrogen became valuable, would epend upon whether these processes were economical. e believed it to be of importance, therefore, to correct me of the statements of the author, on the ground of actical experience. He would not criticise the figures ven for the process of obtaining nitric acid from atmo- heric nitrogen, as he had had no practical experience of e process, but he would point out that in these figures, e not inconsiderable cost of concentrating the dilute id seemed to have been omitted. On the other hand, could furnish some information as to the cost of manu- cture of the product, obtained from calcium carbide id nitrogen, called "Kalkstickstoff" (crude calcium anamide). The cost of manufacture of carbide given rresponded in general to that obtaining in practice, z., a yield of 2·1 tons of carbide per kilowatt-year, a cost of 140 francs per ton, with electric energy at 150 ancs per kilowatt-year. This cost was not, however, e actual first cost of the carbide, but represented also a rtain profit for the carbide manufacturer, so that it would be possible to count on carbide at this price, even if it were bought from a carbide factory, and not specially manufactured in the calcium cyanamide works. The statement of the lecturer that one ton of carbide was required to obtain one ton of crude calcium cyanamide was not correct, only 800 kilos. of 80 per cent. carbide being necessary, *i.e.*, one ton of carbide would yield 1·25 tons of crude calcium cyanamide containing 20 per cent. of nitrogen. The statement that the nitrogen used in the process cost 10 centimes per kilo. also needed correction. The nitrogen was isolated from the air either by chemically fixing the oxygen, or by mechanical means, *e.g.*, by Linde's process. The cost of the latter process varied according as electric power or coal was used. Linde himself stated that oxygen obtained by his process, even when a tolerably dear fuel was used (25 francs per ton), cost about 6—7 centimes per cb. m. Since for each cb. m. of oxygen about 4 cb. m. of nitrogen would be obtained, the price of 10 centimes per kilo. for nitrogen, given by the lecturer, was much too high. The other estimated general expenses were also much too high. These varied according to local conditions, but practical working had shown that the cost per kilo. of nitrogen combined in calcium cyanamide was considerably less than the 1·35 francs given by the author; indeed, the manufacture of crude calcium cyanamide would still be remunerative if the price of nitrate-nitrogen fell to 1 franc. per kilo. For nitrate, on the other hand, the position of affairs was very different; the very accurate, exhaustive investigations of Sempers and Michels (Z. Berg.-Hütten-u. Salinewesen, 1904, 359) had shown that the price of Chili saltpetre could not fall below 20 francs per 100 kilos., free at London, that is, the Chili saltpetre industry is capable of existence only with a price of 1.35 francs per kilo. of nitrogen. This fact would furnish an answer to Sir W. Ramsay, who inquired as to the prospects of the calcium cyanamide manufacture if the price of Chili saltpetre fell below its present value (1.55 francs per kilo. of nitrogen). Calcium cyanamide was a substance which could not only be used directly in agriculture, for which purpose it was eminently suitable, as it contained a high percentage (20 per cent.) of nitrogen, which was not reduced on keeping, and gave in practice results at least equal to those obtained with sodium nitrate and ammonium sulphate, but which could also serve as raw material for the preparation of numerous other nitrogenous compounds, in which the price of 1 kilo. of nitrogen was much higher than in calcium cyanamide. The crude calcium cyanamide, consisting of a mixture of calcium cyanamide and carbon, was suitable for the hardening of iron. The separated carbon was of a graphitic character, and the calcium cyanamide belonged to that class of carbon-nitrogen compounds capable of yielding carbon (in the form of graphite) to iron. A mixture of crude calcium cyanamide and a flux has been prepared under the name "Ferrodur," and has proved excellent for hardening iron. Pure cyanamide and its polymerisation product, dicyandiamide, obtained from calcium cyanamide, form the raw materials for the preparation of a large number of important substances. From cyanamide, urea and guanidine are prepared. Dicyandiamide may be used as an addition to explosives; it does not reduce the shattering effect of the explosive, as large quantities of gas are evolved in its decomposition, but it diminishes the temperature of the products of explosion. According to the most recent investigations of Professor Scalliazzoni, dicyandiamide should also be the most active product for agricultural purposes, as calcium cyanamide, when applied as a manure, is first converted into dicyandiamide. If that observation were confirmed, dicyandiamide would represent a fertiliser *non plus ultra*, since, owing to its containing 66 per cent. of nitrogen, the expenses of freight and transport would be reduced to a minimum. A further application of cyanamide rested on the fact that its alkali salts served as good condensing agents in the preparation of indigo from phenylglycin. Calcium cyanamide was also largely used for the technical manufacture of cyanides. In the fused state calcium cyanamide reacted with carbon, with the formation of cyanide, and this process was now used on the large scale for the manufacture of potassium cyanide. By the action of steam

on calcium cyanamide the whole of the nitrogen was converted into ammonia. Since ammonia was converted into nitric acid under the influence of catalytic agents, and the oxygen necessary for the reaction was available after the separation of the nitrogen from the air in the manufacture of calcium cyanamide, this latter compound might also be looked upon as an intermediate product in the manufacture of nitric acid from atmospheric nitrogen by a method which would probably be more economical than the direct combustion of nitrogen in oxygen. In the preparation of calcium cyanamide, and of ammonia and nitric acid therefrom, the power-consuming reaction was that concerned in the manufacture of carbide. Theoretically 1400—1500 kilos. of nitrogen could be fixed in the form of calcium cyanamide per kilowatt year; actually, 2·5—2·6 tons of calcium cyanamide were produced, that is, 500—520 kilos. of nitrogen fixed. According to the figures of Haber and Muthmann and Hofer, only 380 kilos. of nitrogen per kilowatt-year could be fixed by the direct combustion of nitrogen in oxygen, and actually only 140 kilos. of nitrogen were so fixed in practice. The calcium cyanamide process had thus attained, in practical working, a yield of nitrogen fixed, considerably higher than that theoretically possible by the direct process. In conclusion, the speaker claimed that the process devised by Prof. Frank and himself for the fixation of atmospheric nitrogen by carbides, together with its numerous extensions, represented a method of utilising, in the future, atmospheric nitrogen both for agricultural purposes and for chemical industry.

Dr. J. A. Voelcker said that the subject from its agricultural bearings was most interesting. All the attempts which had been made to supply nitrogen for the farmer's use resolved themselves in a question, as to the Chairman had said, of economy in production, and when all was said and done, and although great hopes had been raised by Sir William Crookes, people were apt to be led on a little too far in their conclusions. He did not think that even if nitrogen could be supplied free from the atmosphere a solution would be found for the many difficulties attending farming at the present time. Still, it would certainly form an advance, and an important advance, though its ultimate success had to be considered purely from the economical point of view. The present subject resolved itself into a consideration of whether either of the two materials mentioned in the paper they had listened to could be produced at a cost less than that of other materials which the farmer was in the habit of using at the present time. Naturally, too, there came the question of the practical utility of the two materials for agricultural use, and having had some experience with one of them, he might be allowed to briefly mention what this had been. So far, experiments with calcium cyanamide had not borne out the expectations held forth. There were difficulties undoubtedly with respect to its keeping. He had had to do with calcium cyanamide which had been produced in Germany, and after keeping it and testing it in the second year, he found that it had lost a considerable amount of its ammonia. Moreover, experiments in the field with cyanamide in comparison with sulphate of ammonia had led, at the best, to what must be called uncertain results. Both at Rothamstead and at Woburn cyanamide had been tried, and although it was not considered desirable, before making further trials, to publish the actual figures obtained, he must say that the results were not favourable to the cyanamide. He had not as yet had the opportunity of trying nitrate of lime, but so far as he might be allowed to draw a comparison between this and cyanamide, his own inclination would be very much in favour of the calcium nitrate, and still more, of the basic calcium nitrate as made in the improved way which Dr. Messel had suggested. It seemed to him on general grounds that the nitrate of lime was the more natural form in which the material could be utilised by the plant and be handled by the farmer, and there was, to his mind, no reason why it should not act as well as nitrate of soda, the value of which was universally recognised. Further, the presence of lime, especially for land in which lime was wanting, would prove an additional benefit. He rather looked in that direction, than in that of cyanamide, for any really practical application of this new discovery, but it all resolved itself, as he had said, into a question of the price at which the calcium nitrate could be produced. He could not form any idea as to how far the figures set out represented the real state of affairs, and he should have liked more definite information on these points, for it was there that the difficulty would be found. If the estimates for production, repairs, general expenses, and the other items of packing and transport were really correct, well and good: but if they were not, the farmer would undoubtedly still keep on using nitrate of soda as before.

Dr. Bernard Dyer said the matter, in this stage, was essentially a problem of chemical engineering. It was no longer a question of chemistry. They knew all about the application of nitrogen when they had it, and what they wanted to know now was, what the prospects were of getting it economically in either of these ways. He thought the calcium nitrate was more likely to be useful to the farmer, but they required to know whether these early developments were going to be practically developed, and they would need a good deal of experience before that could be decided.

Mr. Bingham said the author had correctly stated that the whole question of the cost of the manufacture of nitrate of lime was based on the cost of the carbide, and he thought these figures of the manufacture of carbide were entirely illusory. It was quite true Dr. Caro had considerably improved the aspect of the subject, but from his statements it appeared that he employed a very poor carbide, 68 per cent., which at present could not possibly be sold for use in acetylene lighting. So that the suggestion made by Sir William Ramsay that the surplus production could be used for making nitrate of lime, to a great extent fell to the ground. He must point out that there was only one carbide factory in Norway and Sweden which could obtain lime at 15 frs. per ton. At most places it cost nearly double that figure, chiefly owing to the fact that to get good acetylene carbide the raw material had to be imported from foreign countries. The point he wished to make was this: the author had very correctly stated that there were some carbide factories which could make 6 kilos. of carbide per kilowatt-day, but there was an enormous difference between this amount and 2·1 tons per year. If you divided the latter figure by 6 kilos., that meant a working year of 350 days. He did not know of a single carbide factory able to work 350 days consecutively night and day, and in his opinion, it was very risky to count upon such a basis. There might be factories in existence, he believed there was one, which did succeed in working 350 days. There were waterfalls, like one which was now being harnessed in Norway, giving about 100,000 horse power, and if they could harness two or three thousand they could, as a rule, reckon on getting power all the year round, especially if the plant were duplicated. But if that were done, the figure of 6 frs. for depreciation was absolutely out of the question. Even without duplicating the plant, assuming all went well, the figure of 6 frs. for depreciation was, in his opinion, much too low. Still it was fair if you took a poor carbide of 80 per cent.; and if it was possible, which he believed it was, to use a carbide which was not suitable for lighting purposes, containing a high percentage of phosphorus, you might produce carbide at £6 a ton, and he believed that was the figure originally calculated by Dr. Frank; at any rate, it was the figure contained in some papers sent from him. At the same time, no doubt, the fact that the extra cost of carbide was to a great extent neutralised, as Dr. Caro had pointed out, by the much higher yield of nitrate of lime obtained from a ton of carbide than was shown in the figures, therefore it really seemed possible that the end figures might actually be obtained in practice.

Mr. R. J. Friswell said a very important remark fell from the author when he called attention to the fact, that if power were raised by Mond gas as it stood at present, they would have the cost per kilo. of nitrogen

fixation coming out at about 15 pence. That was the price which he calculated in his table as being the price per kilo. of nitrogen from Chilian nitrate at about £10 6*s.* 8*d.* a ton. Of course, it was a moot point whether that price was one capable of much reduction. When he was engaged in the manufacture of nitric acid, he devoted some attention to that point, and found that with the prices at which the nitrate was now being introduced into Europe, there were large numbers of beds of Chilian nitrate which were said to be not worth working. It was really only a few of the deposits which paid to work at present prices. So that unless that price was artificial, there did not seem any very great margin for reduction. Owing to the enormous troubles which appeared to accompany the production of electricity in mountainous countries by means of water power, they were driven to look to its production by means of producer-gas. There was still a great deal to be done in reducing the price of power generated in that way. Professor Guye correctly stated that at present it costs about 50*s.* per horse power per year, but there was no doubt that when improved methods of scrubbing producer-gas were introduced, so as to get better results in gas engines, that price could be considerably reduced. If that were so, then they would have an opportunity of reducing the cost of the oxidised nitrogen. But after all, that was a comparatively small matter compared with another point. All the author's calculations were based on the production of 500 kilos. per kilowatt-year of nitric acid. If, theoretically, it was possible to produce 800 kilos. per kilowatt-year, that meant that at present they were only producing five-eighths of the possible amount. Evidently there was great room for improvement in the yield of the nitric acid. Taking that in conjunction with a higher power from engines driven by producer gas, it appeared to him that the possibility of the production of nitric acid by such means was extremely hopeful.

Mr. W. F. Reid said he would like to look at the matter from the general point of view, namely, the great advances which had been made in industrial chemistry through either of these processes. They had now in their hands such means of fixing the nitrogen of the air that it was only a question of cost, and in this they were getting so close to the natural sources of nitrogen, that it became a question of fractions of a penny only. This question of the fixation of nitrogen had always been a fascinating one for chemists. The very first practical fixation was by a French chemist in 1777. Instructions were issued in that year for the management of the "nitrières" for the production of saltpetre in France, when the supply was cut off through our British Navy. They then formed these nitre plantations, and used their sewage to make saltpetre for the preparation of gunpowder. That was a practical utilisation of their sewage which was the beginning of the fixation of nitrogen, and also of the bacterial treatment of sewage on a large scale. He did not think Dr. Caro, although he had given one or two of the applications of calcium cyanamide, had fully done justice to the developments which were possible with that extremely interesting product. He heard Dr. Frank's paper at Rome, and he mentioned guanidine, and some other substances which could be produced in a very simple way from the calcium cyanamide. Also with regard to the production of nitric acid, the oxygen which was a waste product in distilling liquid air could be used for producing nitric acid cheaply. This process of Dr. Frank could produce nitrate of lime, ammonia, or calcium cyanamide. These were all products which could be used industrially on a large scale, besides other substances which were useful as raw products for fine chemicals. All were interested in the cheap production of nitric acid from a national point of view, for, not having the means of producing it in our own country at present, we were entirely dependent on foreigners for the supply of the chief material for our national defence, and it was only by the introduction of such processes as this in our midst, on the industrial scale, that we should be rendered independent in our national defence should be we attacked.

Mr. Oscar Guttmann said, with regard to the electric production of nitric acid from the air, the author had made the cheapest possible calculations. The electric power at 50 frs. per kilowatt-year was perhaps possible in Switzerland or Norway, but if those who produced electric power there would calculate very carefully, they would find that after some years when their repairs increased and dilapidations were coming on, when the atmospheric and other occurrences would multiply, which Mr. Bingham had mentioned, 50 frs. per kilowatt-year was an impossibility. Another item which was quite impossible in his opinion, having himself managed works in Switzerland, was 10 frs. for wages and general expenses per ton of nitric acid. The mere handling of a ton of nitric acid cost more than 10 frs.; he did not consider even the question of packing, because he took it they must find some means of utilising the nitric acid on the spot.

Then there was the cost of 205 frs. per thousand kilos. of mono hydrate, but in what form was that obtained? Not at all as 1·500 acid. There was no means at present known of producing nitric acid by electricity in a concentration of 1·500 sp. gr. All that was possible with every treatment known to the industry of the engineer was acid between 50 and 60 per cent. Then there was the cost of £10·2 for a ton of mono hydrate, in a form in which it could not be sold at £2 per hundred kilos. as stated, which was the price in England, or at a cost of £14 per ton, as it was in similar places as those where the electric nitric acid was supposed to be made; but it was in a form in which it was worth a great deal less than £14; in a form in which it could not be sold at all in most cases, because there were no means of consuming 50 per cent. acid to such an extent. Thus, in all these calculations which were brought forward by all these lecturers and writers, every one had made the same great mistake. Turning to the question of cyanamide, he fully believed that Dr. Frank and his assistants were approaching the subject in a scientific manner, and that in spite of all the enormous initial difficulties, they were getting wonderfully well on the way to producing something of extraordinary value. He had no wish to say that in these initial stages in which they were—for they had only erected one works of a large character, comparatively recently—they had succeeded in producing their product in the cheapest possible manner. He believed that, like everybody else, they would after years of experience, succeed in making improvements which would enable them to supply what was required. No doubt the calcium carbide industry, which had already achieved such good results, would continue to improve. The cyanamide process was capable of great development in many ways, applicable to so many industries that there was no question that it was one of the most important inorganic compounds which had been brought to their notice for some time. It was only fair to give Dr. Frank and his collaborators time to show what they could do. He could not go into the question of cost because the figures were only known to Dr. Frank and his colleagues, but speaking from what he saw on the subject, it was not yet such as might induce agriculturalist to take the product in place of some form of nitrate of soda. This brought him to the last point. All the figures were given as in England, but, on the other hand they were compared with the cost price as in Switzerland or Norway, which was quite right. Still, nitrate of soda cost the same, probably a little more, in Norway than in England, and therefore you could compare it, although you could not compare nitric acid. Nitrate of soda as a matter of fact had not always been 10*s.* 4*d.* a hundred weight; he had known it a great deal less, in fact, not long ago it was only 8*s.*, and it had dropped within a few days nearly 1*s.*, so that the whole calculation would be thrown out. Be that as it may, he should be confronted with the objection that with the increased consumption of nitrate of soda for agricultural purposes, it was likely to go higher, and the deposits of nitrate of soda being as Prof. Guye said, on the point of exhaustion, they would find it going higher still. But those who said that forgot that in Chili an enormous quantity of nitrate of soda was thrown away every day. They were really working in the manner best characterised by the German mining expression "Raubbau," robbing the ground—

they only took out the best parts of the deposits, and those that could not be worked were thrown back into the trenches. Was it not more likely, with these millions of tons of inferior caliche lying about, that one day a chemist would find means of extracting them profitably? Was it not within practical bounds to ship that waste caliche to other countries and burn it in a mixture with some organic combustible lying about in millions of tons, like peat, thereby utilising both in a manner best calculated to give the best results? Could they not in this way obtain by-products as valuable as were obtained by coking coal, or might not Dr. Mond make use of that and produce a gas which would surpass even his own? Much as electricity had done, much as they had reduced the cost of electrical bleach and other products, he did not think yet that electricity was capable of playing that rôle in the production of manure, which some thought or that chemical products like calcium cyanamide could supersede in a hurry those natural resources like those in Chili, which were certainly well worth a study.

Mr. H. DE MOSENTHAL said he would only refer to two points, one of which had been mentioned by Mr. Guttmann, namely, that the acid produced was only 50 per cent., which would have either to be concentrated, or treated in some way. The other point was in answer to a question the Chairman asked. Strong nitric acid was transported in Germany by rail in tanks.

Prof. H. E. ARMSTRONG said, no doubt these two processes were of great interest, and marked an important step forward in the possibility of dealing with atmospheric nitrogen and making various new compounds, but he could not help thinking a great deal of care needed to be exercised before coming to any definite conclusion with regard to the use of this new material for manurial purposes. Dr. Voelcker had already called attention to the fact that the results obtained in this country had not been altogether satisfactory, and even supposing they had been during a year or two, they would have to await the result during a series of years. They had to learn whether a soil would bear the continued alkaline treatment which it would be subjected to if this were used. They knew already it would not bear continued treatment with sulphate of ammonia; they knew that sodium nitrate was a very superior manurial material on account of its inertness in many respects, and that it was very favourably contrasted with ammonia salts, and this material might suffer from a like objection. But one could not help feeling that the problem was a much bigger one than that. Not only might a great deal be done in the direction Mr. Reid had said, and if they could be as thrifty as the French were, and go back to the old treatment, and save a great deal of the nitrogen now thrown away, it would be of great importance; but there had also been discovered, within recent years, methods of fixing nitrogen in the soil by the agency of bacteria. No doubt that subject was in its earliest stages of investigation, but there was no reason to suppose that in the future they might not discover in the humble bacterium a means of carrying on the necessary manufacture within the soil itself locally all over the world. That was the solution, he took it, to which the agriculturalist looked forward, and that would seem to be the natural solution from that point of view. When the supply of Chili saltpetre was exhausted as a means of making nitric acid, this process would have an enormous value, but he could not help thinking that this discussion had a more or less academic value. In this country it had an altruistic as well as an economic side. He thought they ought not to allow coal to be used for purposes of this kind; the supply was so short that it ought only to be manufactured in countries where water power was available, and the discussion ought to be adjourned to Canadian and South African districts. In this country he did not himself think they should allow even Mond gas to be used for such a purpose.

Prof. Guye wrote as follows in reply:—

"J'ai été très vivement intéressé par les diverses observations présentées à la suite de l'exposé qui je viens de faire du problème electro-chimique de l'azote. Ne pouvant, sans abuser de votre temps, revenir sur les diverses observations, je me permets de renvoyer à la publication detaillée de mon manuscrit qui comprendra quelques notes justificatives à l'appui des chiffres que j'ai donnée. Je tiens seulement à faire remarquer que le prix de revient du carbure de calcium tel que je l'ai établi correspond très semblement à celui des bonnes fabriques de l'Europe Centrale, avec des variantes dans l'importance relative des divers facteurs, mais sans changement appreciable dans le resultat final. En ce qui concerne les gisements du Chili, los renseignements qui m'ont été fournies confirment l'opinion qui a été émise ce soir d'après laquelle les frais d'extraction sont aujourd'hui plus élevés qu'autre fois et ne permettent pas d'entrevoir la possibilité d'une baisse appreciable dans le prix de vente de ce produit.

"En terminant, je tiens encore à insister sur le caractère comparatif des calculs que j'ai présentés, les resultats absolus pouvant suivant les circonstances être plus ou moins largement modifiés. Mon but a été surtout de poser une question, et non de la résoudre."

(Translation.)

"I have been much interested by the various observations made at the close of the account of the electro-chemical problem of nitrogen which I have just given. As I cannot venture to occupy any more of your time, I will only refer to the details which will appear in print, and which will justify the figures which I have given. I will only remark that the cost price of calcium carbide which I have mentioned is practically that of well-placed and successful works in Central Europe, which vary among themselves as to the relative importance of certain factors, but yet which show close agreement in their final estimate. As to the Chili deposits, data with which I have been furnished, confirm the views which have been stated to-night, namely, that the cost of extraction is now higher than formerly, and that no drop in the price of Chili nitrate is likely to occur.

In conclusion, I must again insist on the purely comparative nature of the figures I have given; for circumstances must necessarily modify all absolute figures. My object has been rather to state questions for discussion than to answer them.

New York Section.

Meeting held at Chemists' Club, on Friday, April 20th, 1906.

DR. RUSSELL W. MOORE IN THE CHAIR.

NOTES ON THE OXIDATION OF LINSEED OIL.

BY A. H. SABIN.

It has long been known that linseed oil dries by combining with oxygen, and that in so doing it gains in weight. At least one competent authority says that in drying it gives off water and carbon dioxide; but, as this latter assertion seems incompatible with the gain in weight which all observers have recorded, the following experiment has been made to test the truth of the assertion.

Six weighed glass flasks, of about 600 c.c. capacity each, were fitted with rubber stoppers, through each of which passed two glass tubes, one reaching near the bottom of the flask and the other about an inch below the stopper. These tubes were bent, above the flasks, at right angles, so that they could be joined with bits of rubber tubing, so that a current of pure air could be drawn through the whole. To remove moisture and carbon dioxide, the air was first passed through jars filled with calcium chloride and lumps of caustic potash; and on leaving the apparatus it was again passed through a calcium chloride tube and

caustic potash. One of the flasks was then filled with pure raw linseed oil, from which it was poured into the second flask, and so on until each flask had been wetted with the same oil. The flasks were drained, weighed, and then set up in series and connected as indicated; then a slow current of air was drawn through the apparatus by a filter-pump. It was anticipated that in about ten days the oil film would be dry, and then the flasks would be again weighed, also the drying tube, and the carbonic acid estimated. Considerable care was taken to make the joints tight, although, as the whole apparatus was open to the air at one end, leakage was not expected.

The oil did not, however, uniformly wet the inside of the flasks, but the film at first formed broke up and gathered into drops, and a little pool of oil formed at the bottom of the flask. The flasks were new and clean. After a day or two the oil in the first flask began to bleach and in due course dried, as was shown by the formation of a film of linoxyn, and then dried still further, as indicated by the shrivelling and wrinkling of this film; and all this time, which was about ten days, the oil in the other flasks was not acted on. Then the oil in the second flask began to bleach, and dried; then the oil in the third flask; and, after more than two months, the oil in the sixth flask was finished. Evidently something was done to the air in passing through a flask containing a few hundred mgrms. of oil which prevented it from oxidising any more oil. This seems remarkable, and worthy of record. Possibly it was the removal of ozone; if this should be shown to be true it would account for the fact that oil dries more rapidly out of doors than within, and this is true whether it is in the sun or not. These flasks were not in direct sunlight, but were in a well-lighted room, and directly under a sky-light.

When the calcium chloride and the potash were examined, it was found that they had gained in weight far more than was possible to account for except by leakage; but this is not remarkable, as everyone knows who has tried to make joints tight for a long time; so the original purpose was defeated.

When the flasks were re-weighed it was found that in no two of them was there uniform percentage increase of weight of oil; and the extremes, which were in adjacent flasks, differed so much that one had gained two and a half times as much as the other, the figures being 10·1 and 25·5 per cent. Yet it was the same oil that was put in all these flasks; and the amount which remained in the several flasks was about the same, being about 300 mgrms.

After this, the stoppers were removed from the flasks, which were then hung up, mouth downwards, for several months, and occasionally weighed; no important changes developed. They were then cleaned and re-weighed, and the original weights were thus verified.

An attempt was made to repeat this experiment with greater care, but after a time leakage developed and the experiment was abandoned; but as far as it went it agreed with the one described.

In connection with this it may be well to refer to the work of G. Keppeler, in his studies on the Hargreaves sulphate process, as reported in "Chemische Industrie" for 1905, No. 5, page 173, where he says: "Oxygen, under the influence of certain treatment or of some substances, loses its property of readily effecting oxidation, and heating the oxygen reduces its oxidising power."

It will be remembered that ozone is destroyed by heat or by contact with rubber, or other oxidisable matter.

Dr. P. C. McIlhiney said with regard to the atmospheric oxidation of linseed oil, he had himself found that the same sample of linseed oil would at different times, and under conditions that were apparently the same, absorb very different percentages of oxygen, or at least that the increase of weight on drying was very different.

Obituary.

SIR CHARLES TENNANT, BART.

Sir Charles Tennant of the Glen, Peebleshire, was the grandson of Charles Tennant, the "Wabster Charlie" of Robert Burns. Charles Tennant gave up weaving for bleaching, and removed ultimately to Glasgow. There in 1787, the father-in-law of James Watt, inventor of the steam-engine, had begun to bleach linen by the aid of "Eau de Javelle" obtained from Paris. Charles Tennant with his partner Knox, improved on this by producing a more portable form of bleaching agent—*viz.*, "chloride of lime" or "bleaching powder." With this invention commenced the history of the St. Rollox firm, which became one of the largest in the world. John Tennant succeeded his father, Charles Tennant. Sir Charles, the second son of John Tennant, was born in 1823. Following his school education, he received a business training as an apprentice in Liverpool, and then returned to Glasgow, where he at once made his mark, winning success and fortune by the exercise of business qualities of the highest order. In 1878, he took over the management of the St. Rollox works, of which there were branches at Hepburn-on-Tyne and Manchester, and salt works at Haverton Hill, Durham.

The Steel Company of Scotland was originally formed in 1872, with Sir Charles Tennant as chairman, for the manufacture of malleable iron, and also steel (by the Siemens-Martin process), from the purple ore forming the residue of the pyrites supplied by the Tharsis Company, after burning in the kilns and extraction of copper and sulphur. Though the malleable iron scheme failed, the Steel Company did not, and mild steel was produced for ship-building and engineering purposes. Sir Charles, whose energy had overcome all difficulties in this direction, held the chairmanship of this Steel Company till 1894, and became thereafter honorary president. He was the first chairman of the Tharsis Copper Company, and was a prominent figure among the alkali manufacturers of the United Kingdom who purchased the copper pyrites mines in the south of Spain, which had failed in the hands of the French companies. The enormous concern, which was the outcome of this purchase, was worked up under his able direction. His own firm, Chas. Tennant, Sons, and Company, of St. Rollox, was the principal one of the 40 engaged in the production of Leblanc soda, which entered into combination as the United Alkali Co., Limited, in November, 1890, Sir Charles being elected the honorary president. Among the other posts which he occupied at one time or other, were the vice-chairmanship of the North British Railway, the chairmanship of Nobel's Explosives Company, and the chairmanship of the Union Bank of Scotland. Sir Charles Tennant was an original member of the Society of Chemical Industry.

He received a baronetcy in 1885. He sat in the House of Commons from 1879 to 1886.

Sir Charles died rather suddenly on June 4, at his residence, Broadoaks, Byfleet, at the age of 82 years.

ERRATA.

Journal and Patent Literature.

I.—PLANT, APPARATUS & MACHINERY.

(*Continued from page* 525.)

ENGLISH PATENTS.

Hermetically sealed doors of cylinders and chambers used for creosoting, vacuum pans, and brick-hardening chambers for high pressure and the like purposes; Impts. in ——. A. B. C. Danks, Netherton, Staffs. Eng. Pat. 7752, April 12, 1905.

THE claim is for improvements in the method of making the joint between the door, A, and the chamber, B, in apparatus in which the door is closed and secured by "screw applied radiating arms." K, engaging with slots or staples, b^2, in the end of the chamber. The dished wrought iron door, A, has a heavy cast marginal ring, C, which fits into a rebate, b^4, formed in the ring, b^1, riveted to the end of the chamber. The face of the door ring has a recess, C^2, filled with soft metal which is forced on to a chisel-edged projection, b^3, formed on the face of the rebated surface of the chamber ring, b^1, by the radial arms, K. The latter are actuated by a screw, F^1, and a capstan-wheel, N, working on ball-bearings on the shaft, F, situated axially with regard to the chamber, and carried in a socket, E, mounted so as to pass through the end of the door, A. The ends, k^2, of the radial arms are curved or of a cam shape, and act directly on the outer side, k^4, of the heavy rim riveted to the dished door, A.—W. H. C.

Furnaces; Impts. in ——. J. D. F. Andrews, London. Eng. Pat. 9952, May 11, 1905.

THE fuel is introduced into a "fuel-chamber" which has no grate and is heated by the combustion taking place in an adjacent "combustion-chamber." The gases given off in the "fuel-chamber," and the residual coke are passed through an opening or port into the "combustion-chamber" where they are burnt by air admitted either entirely through the grate of the latter or partially through the grate and partially through the "fuel-chamber."—W. H. C.

Furnaces, muffles and kilns; Impts. in the construction of ——. W. P. Gibbons, Lower Gornal, R. Masters, Dudley, and G. A. Baeddicker, Harborne. Eng. Pat. 13,614, July 3, 1905.

THE furnace or muffle is built above a gas-producer, and the secondary air is pre-heated by passing through the hollow arch of the gas-producer, and through passages in the side walls of the latter. The gases and air are mixed and burnt in an arched combustion chamber situated over the producer and below the furnace or muffle, and the products of combustion are conducted through flues constructed in the floor and side-walls of the latter to two flues above the furnace arch. From these flues the gases may pass either directly to the chimney or stack, or to the interior of the muffle and then to the chimney.—W. H. C.

Chemical action between materials; Processes for obtaining a violent ——, *and apparatus therefor.* C. G. P. de Laval, Stockholm. Eng. Pat. 14,572, July 14, 1905. Under Int. Conv., July 19, 1904.

See Fr. Pat. 356,096 of 1905; this J., 1905, 1311.—T.F.B.

Separation of solid particles from each other; Impts. in the ——. A. P. S. Macquisten, Glasgow. Eng. Pat. 15,119, July 22, 1905.

The invention relates to improvements in the method of separating solid particles from each other, described in Eng. Pat. 25,204 of 1904 (this J., 1906, 112), and consists in the addition of a small proportion of oil or soap to the liquid or pulp. The proportion suggested is 1 part of oil to 5000 or 10,000 parts of liquid or pulp. The particles to be separated are immersed in the liquid, and are brought gently up to or through the surface. The physical condition of the particles, or the surface tension of the liquid is altered, or both effects are obtained. Further, small amounts of acid and of a salt or salts may be added.—W. H. C.

Separating machines; Impts. in ——. W. S. Ayres, Hazleton, Pa., U.S.A. Eng. Pat. 19,913, Oct. 3, 1905.

The claim is for a separating floor, which consists of an endless band on which the materials (coal, ores, minerals, &c.) to be separated are fed from a shoot with an adjustable spout. The band is inclined transversely to the direction of movement of the minerals being treated, and may also be inclined in the direction of the flow. The direction of movement of the materials is controlled by guide-bars arranged across the endless belt, which in a modification of the apparatus may be made up of a number of narrow endless bands placed parallel.—W. H. C.

Drying furnaces for coal and similar materials with several shelves or hearths superposed one above the other. P. Ostertag, Winterthur, Switzerland. Eng. Pat. 20,752, Oct. 13, 1905.

See Fr. Pat. 358,035 of 1905; this J., 1906, 170.—T. F. B.

Agitating and mixing apparatus. L. C. Trent, Van Trent, Cal., U.S.A. Eng. Pat. 20,865, Oct. 14, 1905.

See U.S. Pat. 806,214 of 1905; this J., 1906, 8.—T. F. B.

Screw presses for drying and similar operations; Continuous ——. J. G. Lorrain, London. From American Process Co., New York, U.S.A. Eng. Pat. 26,724, Dec. 21, 1905.

The apparatus consists of a horizontal casing in the shape of the frustum of a cone, into the larger end of which, the material to be pressed is fed from a hopper by a "star-wheel." It is moved along and compressed by the blades of a screw, mounted on a hollow perforated shaft, which extends axially through the casing. Steam can be introduced into the front end of this shaft to moisten the contents of the press, and the expressed liquid escapes through the perforations in the rear end of the hollow shaft, which has a partition in the middle, and through a small perforated cone, which tapers in the reverse direction and is clamped round the shaft just before the outlet end of the casing. The compressed material is delivered through the annular space between the two cones, and is cut off by knives held by the clamps which fasten the smaller cone. The shaft is carried on suitable bearings at each end of the casing; it is rotated by a worm-gear at the inlet end, and has a small central steam pipe leading to the rear end, to blow out the draining portion and the small cone if they become blocked.
—W. H. C.

United States Patents.

Separating metals and other substances from liquids; Apparatus for ——. L. Dion, Assignor to the Americus Electro-Hermatic Co., New York. U.S. Pat. 820,483, May 15, 1906.

A number of horizontal cylindrical filter cages are arranged in vertical rows and covered with filtering material, over which, in each case, works a rotary brush, with bristles extending inward and actuated by means of cams and rods.—C. S.

Filter; Rotary ——. F. A. Evans, Redwood Falls, Minn. U.S. Pat. 820,560, May 15, 1906.

The filtering chamber, which is annular, is fitted with a scraper mounted obliquely, and adjustable both longitudinally and angularly, working over the open parts of the filter, for removing the solid materials from which the liquid has been drained.—C. S.

Drying kiln. J. F. Hanrahan, Buffalo, N.Y. U.S. Pat. 820,865, May 15, 1906.

The drying chamber is provided with an air inlet, extending the whole way along the bottom, and fitted with a damper; also with an air outlet extending all the way along the top, and fitted with a regulator. The heat is supplied by means of a series of pipes, supported by cross-bars, at a sufficient height above the bottom of the chamber to permit the air entering at the bottom to pass to the opposite side of the kiln, before coming entirely under the influence of the heat radiated from the pipes.
—C. S.

Furnace for heating comminuted material. H. K. Kriebel, Philadelphia, Pa. U.S. Pat. 820,931, May 15, 1906.

A number of communicating hearths are mounted one above another, so as to overlap and form a tortuous flue. The furnace is almost entirely surrounded by an air chamber, communicating with a series of horizontal pipes partially embedded in the hearths. Underneath the bottom hearth means are provided for heating the same, to initially start the furnace, and also charging doors with air ports are placed opposite the several hearths.
—C. S.

Furnace for burning comminuted material. H. K. Kriebel, Philadelphia, Pa. U.S. Pat. 820,932, May 15, 1906. (See preceding abstract.)

In place of the air chamber and pipes, the furnace is provided with a boiler and water-jacket, together with lateral communicating means for procuring a circulation of water across the furnace.—C. S.

Liquid purifier. C. Tuckfield, East Molesey. U.S. Pat. 821,207, May 22, 1906.

See Eng. Pat. 16,689 of 1904; this J., 1905, 982.—T. F. B.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 529.)

English Patents.

Coke; Manufacture of ——, *and apparatus therefor.* J. J. Shedlock, Little Bentley, Essex. Eng. Pat. 9588, May 6, 1905.

Small coal or slack of a non-coking character is intimately mixed with about 10 per cent. of liquid hydrocarbons, such as gas-tar, and the mixture is heated so as to render the tar more fluid, and to cause it to enter the pores of the coal. The mixture is then placed in coking chambers heated externally, hot air and steam being also introduced internally, whereby a hard coke is obtained. The volatile matter produced at the same time may be condensed.
—A. G. L.

Distillery refuse known as "pot ale" or spent wash; Treatment of —— *for the production of fuel.* J. T. Connell, F. F. Haldane, and J. Thomson. Eng. Pat. 13,914, July 6, 1905. XVII., page 604.

Retorts for the carbonisation of coal; Vertical ——. H. W. Woodall, Wimborne, and A. M. D. Duckham, Upper Parkstone, Dorset. Eng. Pat. 11,956, June 7, 1905.

Vertical retorts are provided externally with longitudinal ribs projecting so far as to abut against the retort setting, or against the corresponding ribs of adjacent retorts in the same setting.—H. B.

Gas retort settings and regenerator furnaces for the same. E. Körting, Berlin. Eng. Pat. 12,176, June 10, 1905.

The setting, which is adapted for use with horizontal retorts of 3 m. or more in length, is divided into two retort-heating compartments by a partition at right angles to the axis of the retorts. A transverse wall depends into the generator (which is situated beneath the retorts) to a point somewhat below the surface of the fuel, and thus divides the upper regions of the generator and fuel bed into two portions. The gas from the front portion passes up into the front retort-heating compartment, whilst the gas from the rear portion passes up into the rear compartment, mingling in each case with secondary air supplies which have been preheated in the lower portions of the setting. By this means the uniform heating of lengthy retorts is assured.—H. B.

Retorts for the carbonisation of coal; Vertical ——, H. W. Woodall, Wimborne, and A. M. D. Duckham, Upper Parkstone, Dorset. Eng. Pat. 12,289, June 13, 1905.

To prevent the cracking of the top section of a vertical retort which is fed by a mechanical feeding device (such as that described in Eng. Pat. 16,497 of 1903; this J., 1904, 744), the cast iron cover of the retort is provided with an upright flange, forming a tank in which water is circulated, thus keeping the feeding device cool. The cover has a depending flange, the lower edge of which rests upon sand contained in an annular trough surrounding the top of the retort. The sand deadens the vibration and forms a gas-tight joint between the cover and the trough.—H. B.

Coal gas; Method of and means for producing or enriching ——. R. Hooton and J. Noble, Ashton-under-Lyne. Eng. Pat. 10,733, May 23, 1905.

Cotton-seed shells or husks, either compressed or not, are introduced along with coal, coal slack, or coal breeze into gas retorts, and carbonised in the usual manner. —H. B.

Gas apparatus; Suction ——. S. Griffin, Bath. Eng. Pat. 14,264, July 11, 1905.

For the automatic supply of fuel to a suction gas-producer in accordance with the varying demand of the connected gas-engine, a mechanical stoker is so connected to any suitable part of the engine or producer as to be actuated intermittently by the pressure of the exhaust gases, or the suction in the producer. For example, a rotatable feeding drum or worm, situated at the base of the fuel hopper, is caused to rotate gradually by means of a ratchet-wheel and pawl arrangement, which is operated by a spring-controlled piston moving in a cylinder which communicates with the exhaust pipe of the gas engine. At each discharge of the exhaust gases, the pressure drives the piston up the cylinder, causing a proportionate slight rotation of the feeding drum or worm, and a corresponding delivery of fuel into the producer.—H. B.

Gases for gas turbines; Treatment of ——. L. Wilson, Greenock. Eng. Pat. 1977, Jan. 26, 1906.

Gas, or oil, and air are compressed separately and admitted through pipes, provided with non-return valves, into a water-jacketed combustion chamber wherein the mixture is ignited electrically, the hot gaseous products rushing at high velocity through a series of water-cooled exit pipes, and impinging upon the blade devices of a turbine. The combustion chamber may also contain water-tubes, the object of the water-cooling devices being to cool the gases to a safe working temperature. The various water-jackets and tubes communicate with a steam drum, the steam produced being utilised. The electric ignition of the gases is timed by means of an adjustable contact-maker attached to the tapering shank of one of the non-return valves of the inlet pipes.—H. B.

Internal combustion motors; Method of producing a working medium for ——. P. Winand, Cologne. Eng. Pat. 3006, Feb. 7, 1906. Under Int. Conv., Feb. 8, 1905.

For the production of a working fluid for internal combustion motors operating with exclusion of air (*e.g.*, in submarine vessels), the combustion of volatile hydrocarbon is effected with nitrogen peroxide or some other substance richer in oxygen than air. In order to dilute the explosive mixture to a suitable degree, a portion of the gaseous products of combustion is cooled, and added to the succeeding charge.—H. B.

Incandescing bodies [Mantles] for incandescent lighting; Manufacture of ——. E. Hirsch, Berlin. Eng. Pat. 9864, May 10, 1905.

Mantles, which have been manufactured and burned off in the usual way, are dipped into a 5 per cent. solution of zirconium nitrate, dried, and then collodionised as usual. Mantles so treated, if crushed whilst in a stiffened condition, do not fall to pieces on burning off the collodion. —H. B.

United States Patents.

[*Calcium carbide*]. *Calcium oxide; Process of reducing* — —. T. L. Willson, Assignor to Union Carbide Co. U.S. Pat. 820,031, May 8, 1906. XIA., page 594.

Gas; Process of producing ——. B. E. Eldred, New York, Assignor to Combustion Utilities Co., New York. U.S. Pat., 820,485, May 15, 1906.

Claim is made for a process of passing the waste gases from a blast furnace through a deep bed of hot fuel, which may be treated alternately with a current of air. The product from the blast furnace gases is purified by cooling and washing, before delivery to a gas engine.—C. A. M.

Gases; Method of treating and utilising ——. F. W. Schniewind, Everett, Mass., Assignor to The United Coke and Gas Co., Charleston, W. Va., U.S.A. U.S. Pat. 820,525, May 15, 1906.

The richer gases that are produced first in carbonising carbonaceous fuels in retorts, are drawn off separately, and used for illuminating or other purposes. The poorer gases subsequently produced are collected in separate receptacles, and treated so as to separate their more condensable illuminants, by condensing and washing them to remove tarry and other impurities, or extracting these illuminants with oil from which they are afterwards separated by distillation. The residual gases from which the more condensable illuminants have been removed, may be used for heating the retorts in which the gases are generated.—C. A. M.

[*Oil*] *Gas; Apparatus for making* ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 821,594, May 22, 1906.

The apparatus described consists of a suitably-lined casing, divided into two compartments by a vertical wall, which extends from the bottom to near the top of the casing; the two compartments communicate with each other over the top of this wall, and are packed with regenerative material. An oil-supply pipe discharges direct into the chamber common to both compartments above the wall, and there are steam and air inlets to the bottom of each compartment. There is an outlet for the products of combustion from the bottom of each compartment, and means for controlling independently the inlets and outlets, and a conduit to carry off the manufactured gas from the bottom of each compartment. The conduits communicate with a common washer, and means are provided for controlling the passage of the gas through either conduit.—W. C. H.

Gas; Process of making ——. F. Dannert, Assignor to J. A. Hutmacher, Berlin. U.S. Pat. 821,928, May 29, 1906.

See Eng. Pat. 19,995 of 1905; this J., 1906, 114.—T. F. B.

Gas; Apparatus for purifying ——. A. Elsenhans, Rüttenscheid, Germany. U.S. Pat. 820,772, May 15, 1906.

See Fr. Pat. 360,361 of 1905; this J., 1906, 466.—T. F. B.

FRENCH PATENTS.

Generator for gas, vapours, or liquids from closed vessels. R. Desouches. First Addition, dated March 21, 1905, to Fr. Pat. 343,390, May 24, 1904 (this J., 1904, 1021).

THIS addition to the principal patent relates to a form of the apparatus, which consists of a series of primary generators, communicating with one another and with the carburetter; a convenient number of these generators is arranged inside a common envelope, through which passes a heating agent, preferably fluid, so that the liquefaction, distillation, or dissociation of the products to be converted into gases or fluids is effected by the heat of the gases escaping from the motor, which pass through the envelope. The generators or reservoirs may be of rectangular or elongated ovoid form, and may be closed by screw stoppers, arranged inside the common envelope, to allow of filling them from the outside. There is also an auxiliary generator, with a separate heating arrangement, as, for instance, a burner, to produce a quick distillation to start the motor; this may be used alone, or in conjunction with the main generating apparatus. The claims also include the use of lattice work or metallic web to increase the transmission of heat and the rapidity of distillation or gasification.—W. C. H.

Generator for gas, vapours, fluids, or liquids — . R. Desouches. Fr. Pat. 360,982, March 21, 1905.

A SERIES of generating chambers, each supplied with a manhole and cover, and all communicating by means of valved tubes, is placed within a common envelope. The space between this envelope and the generators can be heated to any required degree by the circulation of waste gases, or by other convenient means. At the beginning of the series is an auxiliary generator containing the substances to be treated, which can be heated externally in any convenient manner and to any required degree, so as to distil, vaporise or dissociate the said substances; the products are "aspirated" through the apparatus at any desired rate.—J. H. C.

Producer for the treatment of all kinds of combustibles. V. Sépulchre. Fr. Pat. 361,127, March 25, 1905.

THE producer is constructed like a blast-furnace, with tuyères at the lower portions, so as to develop such an intense heat that the non-combustible matters of the fuel become fused, and are allowed to flow out in the form of slag or matte. If the fuel is rich in pyrites, a matte containing sulphide of iron is obtained. An appropriate flux may be added. The fuel is charged into the producer through a double cup-and-cone device, and falls first into a cylindrical casing, open at the bottom, which depends a certain distance into the combustion chamber; whilst in this casing, the fuel undergoes a preliminary distillation, the volatile products being either led down to the incandescent zone of the fuel, or treated separately for the utilisation of by-products. The fuel in the casing gradually subsides into the main combustion chamber, as the fuel in the latter is consumed. The casing is suspended from the cover of the producer, and its height can be varied, a water-seal preventing ingress of the producer gases at the top.—H. B.

Gas-generator with automatic outlet for ashes. A. von Kerpely. Fr. Pat. 360,965, Dec. 27, 1905.

THE bottom of the generator consists of a sort of rotating basin which delivers the ashes against and over an inclined plate fixed at one point on its circumference.—J. H. C.

Gases of a gaseous mixture; Process for separating the —. F. Capron. Fr. Pat. 362,155, Jan. 4, 1906. Under Int. Conv., Jan. 22, 1905.

THE gaseous mixture is led through a chamber containing porous partitions or enclosures, whereby a partial separation of the gases in accordance with the laws of diffusion is effected. The process is repeated with the fractions obtained, until the desired degree of purity is arrived at. —H. B.

Sulphur and cyanides from spent oxide, &c.; Proce and apparatus for the extraction of —. J. J. Bécigneul. Second Addition, dated Nov. 25, 190 to Fr. Pat. 345,071, July 23, 1904. (See this J., 190 1216; 1905, 1067.)

IN addition to the solvents for sulphur mentioned in t principal patent and first addition, any of the hydr carbons obtained by the distillation of tar oil may used; and for the removal of tarry matters from t sulphur solutions, any porous substance containi carbon may be employed.—H. B.

Incandescent filaments [Vacuum arc lamp]; Process Manufacture of —. A. Frankfurther and H. Kul mann. First Addition, dated Nov. 13, 1905, to F Pat. 356,999, Aug. 17, 1905 (this J., 1906, 12).

INCANDESCENCE filaments made of pure graphite, described in the principal patent, are here used in t construction of vacuum arc-lamps operating with eith direct or alternating currents. In both kinds of lam the electromagnetic arrangements are designed to wit draw the graphite electrodes from each other to a pr determined, invariable distance, since no combustion the carbons occurs and no automatic regulation of t distance between the carbons is necessary.—H. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

(*Continued from page* 530.)

Coal tars. E. Börnstein. Ber., 1906, **39**, 1238—124

IN a previous communication (this J., 1903, 83) referen was made to the presence of catechol in tar liquo obtained by decomposing German coals at the lowe possible temperature. In the course of the same inves gation tars were obtained differing considerably fro ordinary gas-tar and resembling the Jameson coke-ov tars described by Watson Smith (this J., 1883, 49 One specimen, however, obtained from Westphali coal of the Altendorf pit behaved differently. Wh distilled at 500° C., this coal furnished a tar, which w free from paraffin and naphthalene, and had a sp. gr. 1·03. The fraction distilling above 350° C. gave oil, which on cooling, deposited fine, greenish-yello crystals, consisting of a mixture of methylanthracen $C_{15}H_{12}$, and "crackene," $C_{24}H_{18}$. A similar fraction w obtained from tars produced by decomposing Westphali coal from two adjacent pits, Baaker Mulde and Hambur and it would therefore appear that these types of co which yield a high percentage of coke, furnish ta poor in hydrogen, containing no solid paraffins, b yielding solid aromatic hydrocarbons of high boili point.—D. B.

Petroleum industry of Roumania. For. Off. Ann. Serie 1906, No. 3618. [T. R.]

THE petroleum industry of Roumania is steadily develo ing. The total production of crude oil in 1905 was abo 601,700 tons, or double the production of four years ag The total export was 214,348 tons as against 160,442 to in 1904, and 126,227 tons in 1903. France took 55 per cen of the export of 1905, comprising 11,790 tons of crud 79,766 tons of refined oil, and 27,369 tons of benzin Germany took 17 per cent., the United Kingdom 10 p cent. (entirely refined petroleum), and Austria-Hunga 9 per cent. of the total. The late disturbances in t Baku petroleum fields did not appreciably benefit t Roumanian industry.

ENGLISH PATENTS.

Coke ovens; Regenerative —. E. Coppée, Brussel Eng. Pat. 14,485, July 13, 1905.

SEE Fr. Pat. 359,888 of 1905; this J., 1906, 468.—T.F.

Ammoniacal liquor obtained by washing illuminating and heating gases; Treatment of certain products of ——. J. Radcliffe, Elland, Yorks. Eng. Pat. 10,075, May 13, 1905.

The "spent liquor" remaining from the recovery of ammonia from gas-liquor, &c., is neutralised, or rendered slightly acid, preferably by hydrochloric or sulphurous acid, and is fed at a fixed rate into a receptacle which also receives in like manner solution of a copper salt, regulated so as to precipitate as copper thiocyanate the thiocyanate compounds present, the process being made continuous. The copper salt may be in the cuprous or the cupric state, but in the latter case, sulphurous acid must be present, or be added, in sufficient proportion to effect its reduction. The foul gases remaining after absorption of the ammonia distilled from the gas-liquor, may be burnt, and the sulphur dioxide formed, be absorbed in any usual way, and utilised in neutralising the spent liquor. The copper thiocyanate precipitated may be withdrawn as sludge from time to time, separated by filter-pressing, and then treated with alkalis to recover cuprous oxide, and obtain marketable compounds of cyanogen. Should the "spent liquor" thus freed from thiocyanate contain any copper (added in excess), this may be precipitated by lime or an alkali, or removed by passing the effluent through a channel containing iron, before it is discharged in an innocuous state. It is stated that "spent liquor," after undergoing the described treatment, has a beneficial effect when added in the bacterial treatment of sewage.—E. S.

Petroleum and mineral oils; Refining ——. T. Macalpine, J. F. Simmance, and J. Abady, London. Eng. Pat. 11,893, June 6, 1905.

The oil is neutralised by agitating it with about 5 per cent. by weight of a solution in water of sodium carbonate (1 lb. of sodium carbonate to 10 of water), for half an hour, and the oil is then distilled and agitated with about 5 per cent. of sulphuric acid of sp. gr. about 1·72 for about half an hour at 40° C., to throw down the tarry substances. After settling for four to five hours, and running off from the sediment, the oil is transferred to a still fitted with an inverted condenser, and is treated with about 5 per cent. of finely-ground manganese dioxide or other suitable oxidising agent, together with 10 per cent. of sulphuric acid of sp. gr. not exceeding 1·2. The mixture is quickly heated to about 110° C., and maintained thereat until the remaining impurities are oxidised; after settling and separation from the sediment, the oil is refined and distilled in the usual way.—C. S.

United States Patent.

Distilling coals and other hydrocarbonaceous substances; Apparatus for ——. H. Wurtz, Newark, N.J., Assignor to American Chemical Eduction Co. U.S. Pat. 821,323, May 22, 1906.

In the apparatus described the coals or other hydrocarbonaceous substances to be distilled are placed upon spaced and "staggered" trays, arranged in a casing in a compartment, which casing can be moved into the compartment during distillation, and moved out of it for the discharge of the coke and for recharging with fresh coal. Heat is supplied from one or more fire-chambers, which are separated from the compartment by a partition or partitions. The heat passes through flues to the compartment, and takes a zig-zag course over the substance to be heated, and under and around the ends of the trays, the other end of the compartment being connected with an exhaust pipe; openings leading to the heat-flues are also arranged in the walls of the compartment. By means of the exhaust, heated products of combustion are drawn from the fire-chambers, through the flues and openings, over and around the trays, together with the products of distillation; means are provided for controlling the inflow of the products of combustion to the compartment, within which is a valve chamber or chambers with valves for controlling the temperature in the compartment. The products of combustion and distillation are also drawn by the exhaust out of the compartment. Fuel magazines, with water-sealed tops, are arranged above the fire chambers.—W. C. H.

German Patent.

Saturator for the manufacture of ammonium sulphate. Berlin-Anhaltische Maschinenbau A.-G. Ger. Pat. 165,308, March 25, 1903.

A small saturation-chamber is constructed in the upper part of the bell immersed in the liquid contained in the main saturation-vessel. In the bottom of the small saturation chamber is an opening, and communication with the interior of the bell can be opened or closed at will by means of an indented plate or inverted pan, which is arranged over the opening, and can be raised or lowered. Fresh acid is introduced, when required, into the small saturation-chamber, and then, by raising the indented plate, flows into the main saturation-vessel. According to one claim the indented plate is fixed to the lower portion of the ammonia gas-supply pipe, which slides telescopically in the upper part of the pipe.—A. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 531.)

Benzidine and aniline; Combination of [*diazotised*] ——. *Diphenylbidiazoaminobenzene and diphenyldisazoaminobenzene.* L. Vignon. Bull. Soc. Chim., 1906, **35**, 313—315.

The combination of aniline with a tetrazobenzidine salt on the one hand, and of benzidine with a diazobenzene salt on the other, gives rise to the same compound, a yellowish-red substance, of m. pt. 180° C., which is decomposed by acids into aniline and *p.p'*-dihydroxydiphenyl; from this fact and from its elementary analysis, it is established as diphenylbidiazoaminobenzene, $C_6H_5NH.N_2.C_6H_4.C_6H_4.N_2.NHC_6H_5$. The isomeric diphenyldisazoaminobenzene, $NH_2.C_6H_4.N_2.C_6H_4.C_6H_4.N_2.C_6H_4.NH_2$, was obtained by heating 5 grms. of the diazo compound with 50 grms. of aniline and 2·5 grms. of aniline hydrochloride for 48 hours at 50°—60° C. It is a yellowish-red compound, of m. pt. 158°—159° C.

—T. F. B.

Alizarin; Action of ammonia on ——. R. Scholl and M. Parthey. Ber., 1906, **39**, 1201—1206.

The compound obtained by Perger by the action of ammonia on alizarin is shown to be 1-hydroxy-2-aminoanthraquinoneimide. It is formed by heating alizarin with ammonia for five hours at 140° C. Its composition is represented by the formula $C_{14}H_6ONH(OH)(NH_2)$. It is insoluble in ammonia, dissolves in alkalis and acids, and yields an acetyl derivative, thus exhibiting the properties of an aminophenol. When boiled with water, alkalis, or acids, ammonia is given off; by substituting oxygen for the imino group, 1-hydroxy-2-aminoanthraquinone is obtained; whilst by treating with ethyl nitrite, 1-hydroxyanthraquinone is formed. It is further shown, that the alizarinimide obtained by Liebermann and Troschke by heating alizarin with ammonia is identical with 1-hydroxy-2-aminoanthraquinoneimide.—D. B.

English Patents.

Logwood dyestuffs and extract for dyeing purposes; Production of ——. Lepetit, Dollfus and Ganser, Milan, Italy. Eng. Pat. 9604, May 6, 1905. Under Int. Conv., June 4, 1904.

See Fr. Pat. 351,018 of 1905; this J., 1905, 800.—T. F. B.

Dyestuffs; Manufacture of concentrated liquid dyestuffs or easily liquifiable pastes from sulphurised [*sulphide*] ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst a/Main, Germany. Eng. Pat. 9883, May 10, 1905.

Sulphide dyestuffs, isolated from their salts, and

preferably in the form of moist press-cakes, are converted into fluid form by addition of certain quantities of crystallised sodium sulphide; the quantity varies according to the nature of the dyestuff, and when it is increased beyond certain limits, the dyestuffs no longer remain fluid, but become solidified again. 1347 parts of a press-cake, containing about 60 per cent. of dry substance (obtained by melting trinitroaminodiphenylamine with alkali polysulphide, blowing air through the solution of the fused mass, and pressing the product) are stirred with 950 to 1000 parts of crystallised sodium sulphide; the mass becomes fluid, having a viscosity number of 118—120 (water = 82). Such solutions are convenient for transport, being concentrated, and for immediate use in the dye-house. It is advisable not to use too highly oxidised dyestuffs for the process, in order to increase the fluidity of the product, and to reduce the amount of sulphide necessary.—T. F. B.

Dyestuff of the anthraquinone series [Anthracene dyestuff]; Manufacture of a new ——, and of intermediate products for use therein. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 20,359, Oct. 9, 1905.

See Fr. Pat. 358,271 of 1905; this J., 1906, 260.—T. F. B.

Aminophenols; Manufacture of ——. F. Sachs, Berlin. Eng. Pat. 22,412, Nov. 2, 1905.

See Fr. Pat. 359,064 of 1905; this J., 1906, 369.—T. F. B.

Dyestuffs; Manufacture of blue sulphurised [Sulphide] ——. H. W. Lake, London. From Chem. Fabrik Griesheim-Electron, Frankfort-on-the-Maine, Germany. Eng. Pat. 6198, March 14, 1906.

By oxidising *p*-aminophenol and mono-alkyl derivatives of *o*-chloraniline, new stable indophenols are obtained, which yield diphenylamine derivatives by reduction. The latter are converted into sulphide dyestuffs when heated with alkali polysulphides. They differ from the dyestuffs described in Eng. Pat. 7919 of 1901 (see Fr. Pat. 309,898; this J., 1902, 42), in that they do not contain chlorine in the molecule, dye cotton redder shades, and are faster when washed.—D. B.

United States Patents.

Dye; Green-blue sulphur —— [Sulphide dyestuff] and process of making same. P. Julius and E. Münch, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 820,501, May 15, 1906.

See Eng. Pat. 12,854 of 1905; this J., 1905, 885.—T. F. B.

Indigo colouring matters; Reduction of ——. R. Wimmer, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 820,900, May 15, 1906.

See Fr. Pat. 348,360 of 1904; this J., 1905, 495.—T. F. B.

Dye and process of making same; Rhodamine — — [Pyrone dyestuff]. H. A. Bernthsen, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 821,452, May 22, 1906.

See Fr. Pat. 347,546 of 1904; this J., 1905, 329.—T. F. B.

Dye and process of making same; Blue sulphur —— [Sulphide dyestuff]. C. Ris, Basle, Switzerland. U.S. Pat. 821,378, May 22, 1906.

See Fr. Pat. 357,587 of 1905; this J., 1906, 175.—T. F. B.

French Patents.

Inks; Colouring matter for ——, and its manufacture. P. Fireman. First Addition, dated Dec. 12, 1905, to Fr. Pat. 357,912, Sept. 21, 1905.

See U.S. Pat. 802,928 of 1905; this J., 1905, 1180.—T.F.B.

Tanning and colouring materials; Automatic extractor for ——. L. F. Jury. First Addition, dated Dec. 19, 1905, to Fr. Pat. 358,783, Oct. 7, 1905. XIV., page 598.

German Patents.

Hydroxyanthraquinone methyl ethers; Process of preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 166,748, Jan. 17, 1904. Addition to Ger. Pat. 156,762, Sept. 8, 1903 (see this J., 1905, 669).

β-Hydroxyanthraquinone methyl ether is obtained by heating anthraquinone-β-monosulphonic acid with methyl alcohol and alkali hydroxide. The product is said to be of value for the preparation of dyestuffs.—T. F. B.

m-Diarylsulphodiamides; Process for nitrating ——. Act.-Ges. f. Anilinfabr. Ger. Pat. 166,600, Dec. 9, 1904.

m-Diarylsulphodiamides are nitrated by warming with dilute, aqueous nitric acid, with or without addition of a solvent. The nitro groups enter the *p*-positions to the arylsulphamino groups, providing both these are free. The initial material is obtained by the action of 2 mols. of arylsulphochloride on 1 mol. of the *m*-diamine in presence of sodium carbonate. (Compare Eng. Pat. 27,497 of 1904; this J., 1905, 1297.)—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 532.)

Indigo vat; The fermentation ——. H. Wendelstadt and A. Binz. Ber., 1906, **39**, 1627—1631

Indigo can be reduced with zinc dust or other chemical reagents in the smallest utensils, but in the fermentation process of reduction a quantity of at least 12 litres of liquid is necessary to ensure success. The authors find that in small quantities of liquid, with a large air surface, the micro-organisms obtain oxygen from the air instead of reducing the indigo. When air is excluded satisfactory reduction is obtained even in test tubes. This effect of atmospheric oxygen is not due to a re-oxidation of the indigo white, since it is often found advantageous in practice to obtain a "head," which shelters the liquid below it from the air. The indigo maker has already been in the habit of protecting his vats from the air, nominally with the object of restricting the loss of heat. The authors have isolated from the indigo plant a number of bacilli and a red and a white yeast. Only with the white yeast could sterilised indigo extracts be fermented, and it is suggested that the rational employment of pure cultures may be of advantage in this industry.—E. F. A.

Tin; Absorption of ——, by the wool-fibre in tapestry carpet yarn printing. D. Paterson. J. Soc. Dyers and Col., 1906, **22**, 188—189.

It is known that when stannous chloride is employed as a mordant in worsted yarn printing, the wool-fibre becomes harsh and tendered, and contracts to such an extent as to interfere very considerably with the regularity and symmetry of the design. Oxalic acid possesses the property of preventing this corrosive action, and from a series of experiments on the absorption of tin by the fibre during the steaming process, it is shown that this acid in no way affects the absorptive power of the fibre for tin.—D. B.

Tin; Detection of ——, *in woollen goods.* D. Paterson. XXIII., page 610.

ENGLISH PATENTS.

Threads; Apparatus for the manufacture of artificial ——. E. W. Friedrich, Blaton, Belgium. Eng. Pat. 17,381, Aug. 28, 1905. Under Int. Conv., Sept. 7, 1904.

SEE Fr. Pat. 357,172 of 1905; this J., 1906, 70.—T. F. B.

Electrolytic apparatus [for bleaching liquor]. G. G. Hepburn and Mather and Platt, Ltd. Eng. Pat. 12,221, June 13, 1905. XI*A*., page 593.

Vegetable fibres; Dyeing khaki on ——. A. E. Sunderland and Bradford Dyers' Association, Ltd., Bradford. Eng. Pat. 19,205, Sept. 22, 1905.

USE is made of the solubility of metallic oxides in alkaline solutions in the presence of certain organic compounds, such as glycerin, glucose or the like. By adding these substances to solutions of salts of iron, chromium, copper, manganese or nickel, and then caustic alkali, the precipitated hydroxide is redissolved on a further addition of alkali. By impregnating vegetable fibres with these solutions, and slowly drying, the metallic oxide is fixed upon the fibre, and the excess of alkali can be removed by washing.—D. B.

Dyeing bobbins and the like; Machines for ——. C. and R. Wansleben, Crefeld, Germany. Eng. Pat. 3194, Feb. 9, 1906. Under Int. Conv., March 1, 1905.

THE goods to be dyed are secured to an endless band provided with hollow members to receive the spindles. This band is caused to travel through a dye-bath having at the bottom a suction-chamber with perforated top, and then over a second chamber located at the delivery end of the bath, whereby the dye-liquor can be drawn through the goods travelling through the bath, and air sucked through, and superfluous liquor out of the goods immediately after leaving the dye-bath.—D. B.

Evaporator for evaporating the liquid in brewers' wash, spent wash or pot ale from distilleries, sewage, waste or spent dyes, and the like, the evaporator being also applicable as a smoke washer. A. B. Lennox and P. Dawson. Eng. Pat. 9572, May 6, 1905. XVIII*B*., page 605.

Serum or blood albumin for commercial purposes; Treatment of ——, [*Decolorising*]. The Calico Printers' Association, Manchester and W. Warr, Stalybridge, Lancs. Eng. Pat. 10,227, May 16, 1905.

To 1 gall., of serum or a solution of 1 lb. of blood albumin, is added 0·5 oz. of sodium hydrosulphite (hyposulphite) dissolved in a small quantity of water. After stirring the mixture, about 3 oz. of 40 per cent. acetic acid are added, and the whole allowed to stand for at least 24 hours to bleach the albumin. For transport the excess of acid may be neutralised, and the solution evaporated to dryness at a temperature below 100° F.—W. P. S.

Textile fibres; Printing sulphide colours on ——. L. Cassella und Co., Frankfort on Maine, Germany. Eng. Pat. 1300, Jan. 17, 1906. Under Int. Conv., July 15, 1905.

IN order to prevent the corrosion of metal rollers, the sulphide colours are printed together with a mixture of sodium hydrosulphite (hyposulphite) and glycerin. —D. B.

Fabrics; Apparatus for steaming, ageing and drying ——. Mather and Platt, Ltd., and D. P. Smith, Manchester. Eng. Pat. 15,951, Aug. 4, 1905.

INSTEAD of attaching forked hooks to the endless chains at intervals apart as prescribed in Eng. Pat. 20,117 of 1902, it is now directed to provide each link with a projection or finger, which is capable of holding the loose rollers between any contiguous pair when the chains are straight, and release them when bent.—D. B.

Textile piece goods; Apparatus for drying and carbonising ——. Tomlinson-Haas, Ltd., Manchester. From F. Haas, Lennep, Germany. Eng. Pat. 17,836, Sept. 4, 1905.

THE apparatus claimed comprises a series of drying chambers and intermediate heating compartments following one upon the other alternately, so arranged that the cloth passes over suitable guide rollers in a horizontal direction, and the heated air in a direction contrary to the passage of the fabric, and from one side of the chamber to the other in a line with the weft threads of the material. Although the air passes through both sets of compartments, the fabric traverses the drying chambers only, which arrangement permits a better treatment of the goods by enabling a proper regulation of the temperature. In the carbonising chamber into which the material is led after drying, the fabric is arranged in vertical windings. This chamber is excluded from the air circulating through the drying and heating compartments, and is provided with suitable pipes.—D. B.

GERMAN PATENT.

Lithopone; Use of —— *for obtaining a pure, permanent, white discharge.* Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 166,717, July 1, 1904.

THE claim is for the use of lithopone (a mixture of zinc sulphide and barium sulphate) as an addition to hydrosulphite (hyposulphite) discharges mixtures for the purpose of obtaining a pure and permanent white discharge on dyed woollen and half-woollen fabrics. Lithopone is stated to be more active than the zinc-white hitherto employed for the purpose of preventing the re-oxidation of the leuco compounds produced by the discharge of triphenylmethane dyestuffs. Also, printed fabrics on which discharges have been produced by lithopone can be subsequently treated in acid baths without injury. —A. S.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page 537.*)

Calcium sulphate ; Solubility of —— in solutions of ammonium sulphate. J. M. Bell and W. C. Taber. J. of Physical Chem., 1906, **10**, 119—122. Chem. Centr., 1906, **1**, 1689.

SULLIVAN (this J., 1905, 618) has recently shown that the solubility of calcium sulphate in ammonium sulphate solution at 25° C. first decreases, and subsequently increases again as the concentration of the ammonium sulphate becomes greater. No formation of a double salt was observed. In order to ascertain whether the double salt, $CaSO_4.(NH_4)_2SO_4.H_2O$, described by previous investigators is stable only at temperatures above 25° C., the authors determined the solubility of calcium sulphate in ammonium sulphate solutions at 50° C. At this temperature the solubility curve consists of three distinct parts. The solid phases corresponding to the two extreme portions of the curve consist of the pure salts, calcium sulphate and ammonium sulphate, whilst that corresponding to the middle portion is a double salt. The composition of the double salt was ascertained by Bancroft's method (J. of Physical Chem., **6**, 178), which is as follows:—If to a saturated solution, varying quantities of the two components be added, the composition of the solutions remains constant only if the two components are added in the same proportions in which they are present in the solid phase. In this way the composition of the double salt was found to be: $CaSO_4.(NH_4)_2SO_4.2H_2O$.—A. S.

Tin ; Sulphides, selenides, and tellurides of ——. H. Pélabon. Comptes rend., 1906, **142**, 1147—1149.

As sulphur is added gradually to tin, the solidifying point rises rapidly up to 5 per cent. of sulphur, then more gradually up to the composition corresponding to SnS (880° C.). Beyond that, the solidifying point falls, but the investigation cannot be carried farther than about 25 per cent. of sulphur, as sulphur is then lost rapidly by volatilisation when the mixture is heated.

Mixtures of selenium with tin, and of tellurium with tin, show precisely similar phenomena. When the proportion of metalloid exceeds that in the compound, SnR, the solidifying point steadily falls in the case of selenium, and in that of tellurium falls to a eutectic minimum (388° C.) at about 85 per cent. of tellurium, and then rises regularly to the melting point of tellurium. The existence of higher selenides or tellurides than SnR is not marked on the curves of solidifying point.—J. T. D.

Nitrogen ; Apparatus employed for the utilisation of atmospheric ——. A. Neuburger. Z. angew. Chem., 1906, **19**, 977—985.

Nitrate of soda combination. Eng. and Mining J., June 2, 1906. [T. R.]

AT a meeting of the producers and promoters at Iquique, Chili, on March 31, some concessions were made on both sides. It was then agreed that should 96 per cent. of the producers concur by April 3, in forming a new combination on an estimated producing capacity of 3,800,000 tons per year for all of the 147 manufacturing plants, a new agreement would be entered into. At the meeting of April 3 it was found that 99½ per cent. were ready to concur.

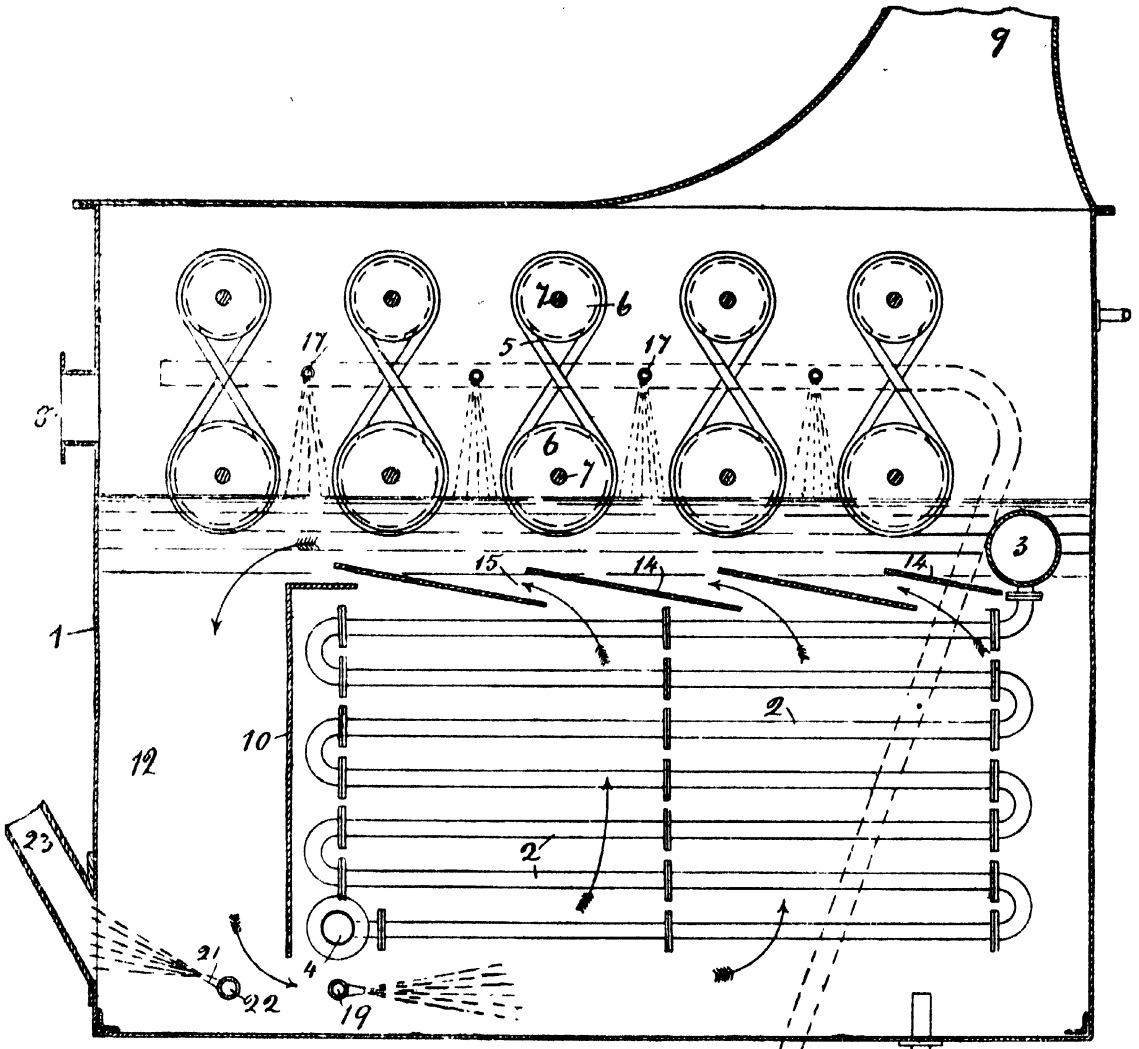
The prospect of having 3,800,000 tons of nitrate thrown on the market during the next twelve months, while there is no prospect that more than 2,000,000 tons will be consumed during the same period, together with the fear that the Chilian Government would legislate against those not entering the combination, was more than the manufacturers were willing to risk.

The term of the new combination is for three years, dating from April 1, 1906, on a basis of a possible producing capacity of all the "oficinas" of 3,800,000 tons yearly, each "oficina" to submit to a *pro rata* reduction in its producing capacity to conform to the consumption of the previous year. The production for the next 12 months will probably be cut down to 2,000,000 tons.

Sulphur Industry ; Sicilian ——. For. Off. Ann. Series, 1906, No. 3595. [T. R.]

THE shipments of sulphur from Sicily last year amounted to 470,341 tons as compared with 508,980 tons in 1904. The total stock existing in Sicily on Dec. 31, 1905, was 462,845 tons.

The Sicilian sulphur industry is passing through a crisis. The producers have become convinced that the American production is seriously threatening them, and most of them agree that an obligatory State-imposed association becomes absolutely necessary for the salvation of the industry. This association would limit the output and guarantee a fair price.



ENGLISH PATENTS.

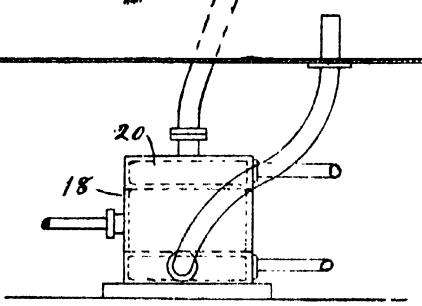
Salt ; Manufacture of common ——. G. R. Ray, Manistee, Mich., U.S.A. Eng. Pat. 5428, March 6, 1906.

THE invention relates to apparatus for supplying anti-incrustation solutions to the ordinary vacuum apparatus for the manufacture of common salt from brine. A relatively small reservoir, containing the solution to be applied in preventing incrustation on the brine-circulating tubes of the vacuum apparatus, is divided into two compartments, in order to supply solution, of different strength if desired, to two pans working in a double effect. Into each compartment, the inlet end of a pipe dips below the surface of the solution, and is then extended horizontally, its outlet end being connected to the brine-supply pipe, so that the two liquids may mingle before entering the pan, above the top of the brine-circulating tubes, and preferably at a point between the top of the tubes and the surface of the brine. The partial vacuum in the pan draws in the solution, which may be caused to flow in at a rate modified by adjusting valves, and by elevating or depressing the reservoir above or below the level of the outlet into the brine pan. There is a pipe for the passage of water into the reservoir, in which, preferably, the anti-incrustation solution is made.—E. S.

Solutions [Brine] ; Means and appliances for concentrating ——, and obtaining and conveying salts. J. Hargreaves, Widnes, Lancs. Eng. Pat. 10,560, May 20, 1905.

THE tank, 1, is divided into compartments by the partition, 10, so as to form a space, 12, for collection of the precipitated salt. The submerged tubes, 2, are heated by exhaust steam from an engine, for example, passed from the inlet tube, 3, to the outlet tube, 4. The sloping covering plates, 14, directing the current of heated brine through the channels, 15, protect the tubing from becoming clogged with salt. Film-exposing surfaces, consisting of cords, 5, passing over pulleys, 6, secured on rotating shafts, 7, dip into the liquid, and carry it upwards for exposure to currents of air drawn over the surface of the brine through the inlet, 8, and outlet, 9. Brine is continuously fed by the pump, 18, having a steam-jacket, 20, through a pipe extending above the liquid, and provided with nozzles, 17, through which the brine issues as spray upon the saline crust as it forms: the salt as it falls upon the surface is swept by the currents in the liquid, shown by the arrows, into the compartment, 12, whence it is driven

up the outlet pipe, 23, by jets, 21, in the pipe, 22, which, as well as the pipe, 19, are supplied with brine from a second pump.—E. S.



Ammoniacal liquor obtained by washing illuminating and heating gases; Treatment of certain products of ——. J. Radcliffe. Eng. Pat. 10,075, May 13, 1905. III., page 584.

Nickel ores or oxidised nickel mattes; Treating ——. R. W. E. Mac-Ivor and M. Fradd, London. Eng. Pat. 10,869, May 24, 1905.

THE mixture of metal oxides, resulting from the roasting of mattes or regulus, is digested under pressure with a strong solution of magnesium chloride, nickel chloride being formed in the solution.—A. G. L.

Hydrogen peroxide; Preparation and purification of ——. C. Poulenc, Paris. Eng. Pat. 1771, Jan. 23, 1906.

SEE Fr. Pat. 359,523 of 1905; this J., 1906, 374.—T. F. B.

Sulphur from sulphuretted hydrogen or gaseous mixtures containing it; Process for obtaining ——. Chem. Fabr. Rhenania, und F. Projahn, of Stolberg 2. Aachen, Germany. Eng. Pat. 3122, Feb. 8, 1906.

IN order to obtain a larger yield of sulphur from gaseous mixtures containing sulphuretted hydrogen, than that obtained by the use of the contact substances hitherto employed in a Claus-kiln, in which the gases pass in a downward direction, the inventors propose the use of

bauxite, or other natural material of similar composition containing alumina or its hydrate, with artificial or natural metal oxides or their hydrates.—W. C. H.

United States Patent.

Cyanogen compounds; Production of ——. C. Bosch, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 821,457, May 22, 1906.

See Fr. Pat. 347,373 of 1904; this J., 1905, 333.—T.F.B.

French Patents.

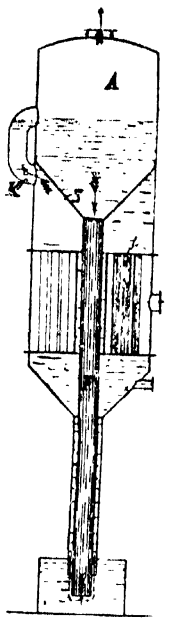
Sulphur and cyanides from spent oxide, &c.; Process and apparatus for the extraction of ——. J. J. M. Bécigneul. Second Addition, dated Nov. 25, 1905, to Fr. Pat. 345,071, July 23, 1904. II., page 583.

Gas-fired furnace for calcining alumina and similar products. R. Brosse. Fr. Pat. 361,268, Dec 30, 1905.

The furnace comprises a series of calcining chambers, each of which has three superposed hearths. A track extends alongside the whole length of the furnace, on which track, wagons containing the alumina to be calcined, travel. The alumina falls from the wagons into vertical conduits at the side of the hearths of each calcining chamber, and is spread on the hearths by means of mechanical rakes. Gas from a producer at one end of the furnace, is delivered to two independent supply pipes extending the whole length of the furnace, from which the gas passes to burners furnished with mixing chambers, and projecting into the calcining chambers. The air is preheated by being drawn through the chambers where the calcination has been completed, and then passes to a conduit below the furnace, whence it is delivered to the burners as required.—A. S.

German Patents.

Muffle furnace for the production of sulphate and hydrochloric acid. K. Oehler, Anilin und Anilinfarbenfabrik. Ger. Pat. 165,099, May 10, 1904.



The furnace communicates, on the one hand, through openings in the bottom, with a channel running underneath the whole length of the furnace, for the purpose of removing the sulphate, and on the other hand, through openings in the roof, with an auxiliary condensing plant. Both sets of openings can be closed. When the hot sulphate is being removed from the furnace, the acid vapours are drawn through the auxiliary condensing plant.—A. S.

Alkali compound that can be easily converted into alkali hydroxide or alkali carbonate; Process for the electrolytic manufacture of — — and of chlorine. J. Wunder. Ger. Pat. 165,487, Sept. 14, 1904. XI.A., page 594.

Magnesium carbonate; Process for the production of voluminous normal ——. O. Brill. Ger. Pat. 164,882, April 4, 1905.

Basic magnesium carbonate obtained by precipitating a solution of a magnesium salt with alkali carbonate, is heated in a current of carbon dioxide, preferably to 150°—220° C. If dry carbon dioxide be employed, an anhydrous product is obtained.—A. S.

Saturator for the manufacture of ammonium sulphate. Berlin-Anhaltische Maschinenbau A.-G. Ger. Pat. 165,308, March 25, 1903. III., page 584.

Evaporator for salt solutions and the like; Vacuum ——, *with separate heating and evaporating chambers.* F. Juergens. Ger. Pat. 165,220, Sept. 29, 1903

The evaporator is shown in section in the figure. It has separate evaporating and heating chambers communicating only by a circulation tube, K. The evaporating chamber, A, is provided at the bottom with a fall-tube, F, and the heating chamber has vertical heating tubes, L. The bottom, E, of the evaporating chamber forms the cover of the heating chamber, and it is claimed that incrustations on the bottom of the evaporating chamber and in the fall-tube are in this way prevented.—A. S.

Sodium nitrate free from perchlorate; Process for the manufacture of ——. E. Egor. Ger. Pat. 165,310, May 19, 1904.

The crude Chile saltpetre is treated, with agitation, with a quantity of cold water exactly sufficient to dissolve the sodium nitrate, in order to obtain a solution of this salt free from impurities. In carrying out the process, the ground material is mixed with a small quantity of cold water (at 10°- 15° C.), and then further quantities of cold water are added gradually, with continuous stirring, until the mixture contains $(100-3a)$ kilos. of water for each 100 kilos. of crude nitre (a = percentage of "potassium nitrate" *plus* "potassium perchlorate"). On the first addition of water the temperature falls below 0° C., and then gradually rises again, so that a solution of sodium nitrate saturated at a relatively low temperature is obtained, and neither potassium nitrate nor potassium chlorate is dissolved.—A. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 537.)

United States Patents.

Sheet-glass; Apparatus for the manufacture of ——. W. B. Keighley, Vineland, N.J. U.S. Pat 820,205, May 8, 1906.

The glass-making furnace or tank is provided with an adjustable block for varying the area of the discharge-outlet, the block having a wedge-bearing on the tank. Means are provided for projecting a fluid under pressure on to the under side of the sheet of glass to support it before it reaches a mechanical conveyor; an electrically-heated severing device, capable of being moved to and from the sheet of glass, is also provided, as well as means for projecting heating and cooling fluids alternately on to the glass, and means for projecting across the whole surface of the sheet a spray of fluid at a uniform temperature lower than that of the sheet.—A. G. L.

Glass sheets; Apparatus for drawing ——. J. H. Lubbers, Allegheny, Assignor to Window Glass Machine Co., Pittsburg. U.S. Pat. 821,724, May 29, 1906.

See Eng. Pat. 22,065 of 1904; this J., 1905, 29.—T. F. B.

Glass; Process and apparatus for drawing sheet ——. I. W. Colburn, E. Washburn, and C. W. Irwin, Franklin, Pa. U.S. Pats. 821,785 and 821,786, May 29, 1906.

See Eng. Pat. 13,788 of 1905; this J., 1905, 1306.—T.F.B.

FRENCH PATENT.

Glass-house pot furnaces, heated by gas. E. Derval. First Addition, dated Dec. 23, 1905, to Fr. Pat. 306,356, Dec. 18, 1900.

THE pot furnaces with a central column, described in the original patent, are, according to this addition, divided into two or more parts, by means of a transverse wall or partition, through which air can circulate, in order to allow of the continuous working of the furnace, and to facilitate the founding in the same furnace, and in the same "journey," of glasses of different compositions. By this arrangement, while the founding is proceeding in pots in one part, pots in another part of the furnace may be kept cool enough to be worked.—W. C. H.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 538.)

Puzzuolanas; Methods for the determination of the hydraulic value of ——. E. Manzella. Gaz. chim. ital., 1906, **36**, 113—123.

VICAT in 1826 (Ann. Chim. Phys., 1826, 197) stated that the hydraulic power of a puzzuolana corresponds to the quantity of lime which it is capable of absorbing from lime-water in a given period of time. The author has examined the modifications of this method proposed by Giorgis and Alvisi (Gaz. chim. ital., **30**, [I], 96). He finds that the use of lime dissolved in a solution of sugar instead of in pure water offers no advantage. The absorptive power of a puzzuolana for lime in aqueous solution increases considerably as the time of contact is prolonged. It is true, as Giorgis and Alvisi found, that clay and "vegetable soil" absorb some lime when placed in contact with lime-water, but the amount absorbed does not increase as the time of contact is prolonged, so that these substances can be readily distinguished from true puzzuolanas. In carrying out Vicat's test, the time of contact of the puzzuolana with the lime-water should be prolonged to more than 12 days, and the mixture should be continually agitated.—A. S.

Concrete; Notes on ——. R. W. Leonard. J. Canadian Min. Inst., 1905, **8**, 102—110.

THE specification common in Canada for Portland cement used in making concrete requires that 95 per cent. shall pass through a 100-mesh sieve, and that the neat cement shall bear a tensile strain per sq. in. at three days of 300 lb; seven days, 450 lb.; twenty-eight days, 600 lb. The initial set should take place in one or two hours, and the final set in five to eight hours. The soundness is tested by a boiling pat test. The specification of the Canadian Society of Civil Engineers, Jan., 1903, is more lenient than the above, and does not include a boiling test. The amount of magnesia is generally specified to be less than 3 per cent.

For sand, it has been found that pit sands (rounded, and made up of different sized grains) are better than crushed granite or quartz (sharp); that a little clay is probably not detrimental; that coarse sand or crushed stone gives a higher tensile strength than fine sand, and that pit sand or crushed limestone gives better results when subjected to abrasion than does sharp granite sand.

The stone is generally specified to be broken so as to pass a two-inch ring, and screened, but a mixture of gravel and sand pumped up together is now often used, and gives good results.

The author praises reinforced concrete work, and gives some examples to show that it may be made watertight, even against considerable heads of water (up to 15 ft.).

Roofing, paving, &c.; Composition for ——. E. J. Yetter, Denver, Colo. U.S. Pat. 819,833, May 8, 1906.

GILSONITE, lime sludge, and asphaltum or an equivalent are combined in suitable proportions with an oil or flux, either incorporated in the asphaltum, or added as a separate ingredient.—A. G. L.

Roofing, paving, &c.; Composition for ——. E. J. Yetter, Denver, Colo. U.S. Pat. 820,162, May 8, 1906.

ELATERITE, lime sludge, and asphaltum or an equivalent are mixed with a suitable oil or flux, either incorporated in the asphaltum, or added as a separate ingredient.
—A. G. L.

Roofing, paving, &c.; Composition for ——. E. J. Yetter, Denver, Colo. U.S. Pat. 820,163, May 8, 1906.

ELATERITE, gilsonite, lime sludge or calcium carbonate, and asphaltum are mixed with a suitable oil or flux, either incorporated in the asphaltum, or added as a separate ingredient.—A. G. L.

Emery; Process for the manufacture of artificial ——. A. Gacon, Montval, France. U.S. Pat. 820,859, May 15, 1906.

SEE Eng. Pat. 23,492 of 1904; this J., 1905, 92.—T. F. B.

Building material; Composition ——. Z. B. Taylor, Orbisonia, Pa. U.S. Pat. 821,550, May 22, 1906.

THE artificial stone is composed of 60 parts of crushed slag, containing 34 parts of silica; 12 parts of alumina; 50 parts of lime, and 4 parts of magnesia; to these 20 parts of cement and 20 parts of clay, or clay and sand, are added, together with sufficient water to make the mass plastic for moulding, a suitable colouring material being also added.—W. C. H.

Cement clinker; Process of burning ——. H. L. Doherty, Madison, Wis. U.S. Pat. 820,484, May 15, 1906.

THE cement is burned in a rotatory kiln, into the lower end of which is injected a mixture of powdered coal with sufficient air for its complete combustion. The air is diluted with products of combustion, the quantity of which is varied from time to time, whereby a periodical shifting of the clinkering zone in the kiln is effected, and the formation of kiln incrustations is avoided. The introduction of air from extraneous sources is prevented.
—A. G. L.

FRENCH PATENTS.

Tiles and stone; Process of manufacturing artificial ——. E. Vajda. Fr. Pat. 361,208. Dec. 19, 1905.

A MIXTURE of 60 to 90 per cent. of cement or other hydraulic binding agent, 30 to 10 of asbestos or other mineral fibre, and 5 to 2 of steatite, is made with water, moulded under a pressure sufficient to expel all surplus water, and, if necessary, subjected to a second moulding under pressure. The addition of steatite is designed to prevent the subsequent absorption of moisture from the air by reason of the greasy nature of the material.

Roads; Dust-free and absolutely firm ——. K. Schmoll von Eisenwerth. Fr. Pat. 360,941, Dec. 26, 1905.

THE formation of dust may be prevented by watering roads already constructed with a 2 to 10 per cent. solution of alkali silicate, preferably sodium silicate, in water, whilst for roads to be made, sodium silicate is added to the water used in their construction.—A. G. L.

X.—METALLURGY.

(*Continued from page* 543.)

Blast furnace slags. O. Boudouard. Rev. gén. Chim., 1906, 137; Chem.-Zeit., 1906, **30**, Rep. 160.

THE author notes that in the production of a ton of cast iron, in general about 1200 kilos. of slag are produced at the same time. This makes an annual production of 60 million tons of slag from iron furnaces alone. If other metallurgical operations be taken into account, there is a yearly production of 100 million tons of slag. Blast furnace slags are now used for road-making and paving; also for mortar, non-conducting media (slag wool), cement, bricks, &c. Slag cement is cheaper than Portland cement. Slags may be divided into two classes:—1, Silicate slags, commercially the most important; 2, non-silicate slags, consisting of acids other than silicic acid (boric, hydrofluoric, phosphoric, hydrochloric, sulphuric, titanic, and vanadic acids) and more or less basic oxides. The importance of the knowledge of the fusibility, melting-point, and viscosity of slags, and its bearing on the production of a given metal is discussed. Some slags possess considerable viscosity over a large range of temperature, and it might be thought, therefore, that the determination of the melting point was of little practical value. The author points out, however, that as the fusibility of a slag is inversely proportional to the amount of heat required to fuse it, and this in turn depends upon the specific heat and melting point of the slag, the melting point is one of the chief factors in determining the fusibility. (See also this J., 1905, 675.)—F. SHDN.

Nickel ores; Chlorinating treatment of ——. F. N. Rutherford. J. Canadian Min. Inst., 1905, **8**, 336—342.

THE author has made a number of experiments on chlorinating roasting applied to low-grade nickel ores after roasting for sulphur. Different mixtures of the roasted ore with raw ore and salt, and with ferrous sulphate and salt, were made, but all gave poor results, especially the ores with very low percentages of nickel. The best result was obtained by heating a mixture of 100 grms. of roasted ore, 15 of salt, 5 of manganese dioxide, and 10 of sulphuric acid to 400° C. for 30 minutes, and leaching with boiling water, 59 per cent. of the nickel in the ore being recovered. Nickel chloride is very easily decomposed and rendered insoluble by heating in the presence of silicates, especially if air be admitted.—A. G. L.

Cobalt-nickel ores; Solubility of ——, *in ammonia.* G. S. Hanes. J. Canadian Min. Inst., 1905, **8**, 358—362.

THE author has made a number of experiments with Malzac's ammonia process for the extraction of nickel, cobalt, and copper from arsenical and sulphide ores. The process consists in treating the ore, crushed to pass a 120-mesh screen, with ammonia solution (one part of ammonia solution of sp. gr. 0·880 to two parts of water), and blowing air through the mixture. Oxidation takes place, and the hydroxides of the metals produced are dissolved by the ammonia. Nickel is acted upon before cobalt, and a rough separation may be made in this way. The air, after leaving the lixiviating apparatus, is passed through washing towers to recover the ammonia. From the solution the metals are conveniently obtained by electrolysis. Proceeding in this way, from a pyrrhotite ore, containing 5·20 per cent. of nickel, 10 hours' blowing yielded 40·0 per cent. of the nickel, and 20 hours' 87·5 per cent. An arsenide ore containing 27·9 per cent. of cobalt and nickel yielded practically the whole after 10 hours' blowing. A copper-nickel matte containing 39·75 per cent. of iron, 9·9 per cent. of copper, and 21·1 per cent. of nickel also yielded the whole of its copper and nickel after 10 hours. (For action of ammonia solution on metallic nickel and cobalt, see Hodgkinson and Baillars, this J., 1895, 160.)—A. G. L.

Antimony and tin; Alloys of ——. F. E. Gallagher. J. of Physical Chem., 1906, **10**, 93—98. Chem. Centr., 1906, **1**, 1690—1691.

REINDERS (Z. anorg. Chem. **25**, 113) has stated that antimony and tin form two compounds, Sb_4Sn_3 or Sb_3Sn_4, and SbSn, whilst Van Bijlert (Z. physik. Chem., **8**, 843) considers the alloy corresponding to the last-mentioned formula to be a solid solution. The author has made a detailed microscopic examination of the alloys, and constructed their cooling curves. He finds that antimony and tin do not form any chemical compound, but give solid solutions, of which α-, β-, γ- and δ- crystals are distinguished. Transformation points at 430° and 243° C. were observed, just as by Reinders, and also at 319° C., instead of the 310° C. given by that author. The cause of this discrepancy is stated to be that the nature of the solid alloy varies considerably according to the rate of cooling, and that under some circumstances unstable systems are formed. For example, the β-crystals are unstable below 313° C., but undergo transformation only very slowly.—A. S.

Sulphide ores; Economical treatment of ——, *For white lead*]. C. B. Jackes. XIIIA., page 596.

Mines and quarries: General report and statistics for 1905. *Part I. District statistics.* [Cd. 2974.] Price 7d. [T. R.]

THIS return, which forms the first part of the General Report on Mines and Quarries for 1905, contains statistics of the number of persons employed, of the output of minerals, and of accidents at mines and quarries in the United Kingdom, arranged according to the inspection districts. The total output of the under-mentioned minerals in the United Kingdom in 1905 as compared with 1904 was as follows:—

	1904.	1905.
	Tons.	Tons.
Coal	232,428,272	236,128,936
Clays and shale	15,948,915	15,134,754
Iron ore	13,774,282	14,590,731
Limestone (other than chalk)	12,043,135	12,501,780
Igneous rocks	5,988,821	5,956,900
Sandstone	5,306,363	5,639,566
Chalk	4,438,728	4,535,584

Zinc or oxide of zinc; Process of extracting —— from its ores. F. W. Howorth, London. From Soc. Anon. Metallurgique Proc. de Laval, Frankfort on Maine, Germany. Eng. Pat. 14,573, July 14, 1905.

SEE Fr. Pat. 356,097 of 1905; this J., 1905, 1311.—T. F. B.

Furnace for roasting, desulphurising, chloridising [chlorinating], dehydrating or drying ores and other substances. A. V. Leggo, Ballarat, Australia. Eng. Pat. 17,370, Aug. 28, 1905.

SEE Fr. Pat. 357,661 of 1905; this J., 1906, 126.—T. F. B.

Furnaces for roasting, desulphurising, chloridising [chlorinating], dehydrating or drying ores, &c. A. V. Leggo, Ballarat, Australia. Eng. Pat. 21,160, Oct. 18, 1905.

THE furnace consists of two or more series of superimposed roasting chambers communicating with each other, and furnished with rabble-shafts carrying arms whereby the material under treatment is conveyed from one chamber to another. The material is fed into the furnace from a hopper, by means of fluted rollers, which can be driven at varying speeds. Solid, liquid, or gaseous fuel may be used. Specially constructed fire-boxes or combustion chambers are provided in certain cases at the discharge ends of the roasting chambers.—J. H. C.

Magnetic materials [Alloys]; Manufacture of ——. R. A. Hadfield, Sheffield. Eng. Pat. 22,130, Oct. 30, 1905. Under Int. Conv., June 8, 1905.

A MAGNETIC material having low hysteresis and eddy current is produced by alloying iron with silicon and a substance other than silicon, such as aluminium, to the extent of 0·35 per cent. up to 8 per cent. of the iron, the amount of this element (aluminium) amounting to from 25 to 75 per cent. of the silicon. The alloy so formed is heated to between 900° and 1100° C., allowed to cool, re-heated to between 700° C. and 850° C., and then left to cool slowly.—J. H. C.

Ores; Process for the balling together of pulverulent or dusty ——. J. E. Goldschmid, Frankfort on Maine, Germany. Eng. Pat. 26,170, Dec. 15, 1905. Under Int. Conv., Jan. 12, 1905.

SEE Fr. Pat. 360,576 of 1905; this J., 1906, 543.—T. F. B.

UNITED STATES PATENTS.

Metal-bearing materials; Process of treating ——. C. W. Merrill, Lead, S.D. U.S. Pat. 820,430, May 15, 1906.

MATERIALS containing precious metals, and especially such materials as also contain reducing agents, are crushed, and treated with a cyanogen-bearing solution in a closed vessel, "and the solution is removed from the interstitial spaces of the material." The material is then subjected to the action of an oxidising agent (air) under a pressure greater than that of the atmosphere, and afterwards again treated with a cyanogen-bearing material. —A. S.

Precious metals; Process of and apparatus for extracting —— from their ores. S. T. Muffly, Assignor to Philadelphia Cyanide Process Co., Philadelphia, Pa. U.S. Pats. 820,810 and 820,811, May 15, 1906.

ORES containing gold and silver are crushed, and then delivered into a neutralising chamber containing an alkaline solution for the purpose of neutralising any acid salts present. The ore is now carried by a conveyor through a valved conduit into a closed casing containing a stamp mortar, in which it is pulverised in an alkaline cyanide solution under a pressure of heated air greater than that of the atmosphere. The pulverised ore is conveyed continuously through a series of lixiviators containing cyanide solution under air pressure, and the solution and tailings are finally collected in separate receptacles. The air, before being discharged, is led through an absorbing chamber provided with a series of partitions forming a tortuous passage, and fed with a "compound alkaline cyanide and alkaline hydrate solution," whereby the hydrocyanic acid gas is absorbed, and vapours of base metals are condensed; the absorbing liquid is subsequently used for treating further quantities of ore. (See also following abstracts.)—A. S.

Lixiviator. S. T. Muffly, Assignor to Philadelphia Cyanide Process Co., Philadelphia, Pa. U.S. Pat. 820,812, May 15, 1906.

THE lixiviator consists of a horizontal receptacle or drum, having inlet and outlet pipes entering it, on opposite sides, at angles other than 90°, and also pipes for supply of compressed air and of solvent liquid. Inside the drum is a revolving device, provided with buckets, which carry the material under treatment, *e.g.*, ore-pulp, from the inlet to the outlet pipe. The air-supply pipe extends through the upper portion of the drum, and has a longitudinal slot, whereby the air is caused to exert a direct downward pressure upon the liquid contained in the drum. (See preceding abstract.)—A. S.

Condensing or dissolving gases and vapours; Process of, and apparatus for ——. S. T. Muffly, Assignor to Philadelphia Cyanide Process Co., Philadelphia, Pa. U.S. Pats. 820,813 and 820,884, May 15, 1906.

THE patents relate to a process of, and apparatus for recovering "gases and base or other metallic elements carried thereby in volatilised or finely-divided form." The gases, under pressure, are exposed to a solution of "a double cyanide of potassium and bromine," and are then passed through a series of thin films of the solution, while mixed with air under pressure. In the solution the base metal compounds are precipitated by an "alkaline hydrate solution containing ammonia." The apparatus consists of a closed chamber, having an inlet and outlet for the gases, and an inlet for compressed air. In the chamber is a series of vertical endless aprons, mounted on rollers, and extending downwards into the solvent liquid contained in the chamber. Between the aprons are vertical partitions reaching from the bottom nearly to the top of the chamber, and having openings to permit of the passage of liquid. The chamber has a false bottom of filtering material, and the space below has an outlet for the filtered solution. After leaving the chamber, the gases and air pass through a closed box fitted with baffle-plates, and provided with an automatic outlet valve, which opens periodically to allow the gases and air to escape. (See also preceding abstracts.)—A. S.

Iron; Process of manufacturing —— direct from its oxide. J. N. Whitman, Philadelphia, Pa., Assignor to M. T. Reynolds, Albany, N.Y. U.S. Pat. 820,898, May 15, 1906.

THE pulverised ore, after suitable mechanical treatment, is heated under oxidising conditions to eliminate the more volatile impurities, and then heated with a "reagent" to remove the remaining impurities. The purified ore is next subjected to heat and agitation "under de-oxidising and carburising conditions produced by the introduction of free carbon, to partially de-oxidise, carburise, partially reduce, and agglomerate the ore into coherent masses," and the product is then subjected to a higher temperature under reducing conditions to effect complete reduction. —A. S.

[Iron] Ores; Process of, and apparatus for smelting ——. J. A. Potter, San Francisco, Cal. U.S. Pats. 821,189 and 821,190, May 22, 1906.

THE apparatus consists of a smelting chamber with an open hearth, surmounted by a dome of refractory material. A conduit acting as a burner for fluid fuel, discharges over the hearth, and a vertical tubular retort, open at the bottom, extends upwards from the dome. The ore is ground with limestone and tarry hydrocarbonaceous material, and the mixture is fed from a hopper into the upper end of the retort. The mass is forced through the retort by means of a plunger, and the hydrocarbonaceous material is gasified, charred, and coked by means of the hot gases from the smelting chamber. The hardened mass issuing from the lower end of the retort falls on to the hearth of the smelting chamber, and is smelted, the molten iron and slag being drawn off at suitable intervals. —A. S.

Steel; Manufacture of ——. J. W. Spencer, Newcastle-on-Tyne. U.S. Pat. 822,082, May 29, 1906.

SEE Eng. Pat. 15,032 of 1903; this J., 1904, 664.—T. F. B.

Copper alloy. G. Chaudoir, jun., Vienna. U.S. Pat. 820,954, May 22, 1906.

SEE Fr. Pat. 335,838 of 1903; this J., 1904, 325.—T. F. B.

Copper and other values; Process of recovering —— from certain ores. T. J. Lovett, Chicago, Ill. U.S. Pat. 821,516, May 22, 1906.

THE patent relates to a combined dry and wet process of concentrating and collecting the non-magnetic sulphide and contained "values" in low-grade chalcopyrite ores containing a considerable percentage of magnetic iron. The ore is coarsely crushed, and treated in a magnetic separator, whereby the iron and the sulphides are roughly separated. The magnetic material is then ground with water, and again treated in a magnetic separator to recover adhering particles of sulphides.—A. S.

Slag; Apparatus for pulverising blast-furnace ——. H. Colloseus, Berlin. U.S. Pat. 821,609, May 29, 1906.

SEE Fr. Pat. 356,379 of 1905; this J., 1906, 26.—T. F. B.

Slag; Process for dissolving solid fluxes in fluid ——. F. C. W. Timm, Hamburg, Germany. U.S. Pat. 822,087, May 29, 1906.

See Fr. Pat. 356,252 of 1905; this J., 1905, 1308.—T.F.B.

Detinning; Method of ——. K. Goldschmidt and J. Weber, Assignors to Th. Goldschmidt, Essen on the Ruhr, Germany. U.S. Pat. 822,115, May 29, 1906.

See Fr. Pat. 356,228 of 1905; this J., 1905, 1311.—T. F. B.

French Patents.

Bronzo-nickel. Soc. Anon. du Bronzo-nickel. Fr. Pat. 360,910, March 18, 1905.

"Bronzo-nickel" is an alloy formed by melting together 10 parts of nickel, 65 of copper or of bronze, 25 of zinc, 5 of antimony, and phosphorus, borax, and magnesium to facilitate the mixing. The melting-point of the alloy formed is given as 1400° C.; it is said to resist the action of moisture, sea-water, and dilute acid.—A. G. L.

Furnace, reverberatory or blast; Process for carrying out chemical and metallurgical operations in a —— [*Furnace for casting steel, puddling, or reducing zinc, &c.*] *by introducing mixtures of gas and air at two or more points.* Schmidt and Desgraz. Fr. Pat. 361,189, Dec. 30, 1905. Under Int. Conv., June 5, 1905.

Mixtures of gas and air, varying in composition according to the nature of the operation to be carried out, are introduced into the furnace at two or more points. Thus, in a Bessemer convertor for steel, during certain stages of the blow, an oxidising mixture may be blown in from a lower tuyère and a reducing mixture from an upper tuyère, whilst towards the end of the blow the reverse procedure may be adopted.—A. G. L.

Silicon combined with calcium or its compounds; Thermic process based on the action of ——. J. Goldschmidt. Fr. Pat. 361,197, Dec. 30, 1905.

The invention consists in replacing the aluminium in thermite by a mixture of silicon and calcium. Thus, a mixture of 20 per cent. of calcium, 10 of silicon, and 70 of ferric oxide or magnetic iron oxide, will give a very liquid slag of calcium silicate and a large amount of metallic iron, considerable heat being evolved. Metallic aluminium or magnesium may be mixed with the calcium-silicon mixture, and other oxides, *e.g.*, of chromium, may be substituted for the ferric oxide, if it is desired to obtain different alloys, or (from the slag) different opaque or transparent products. Neither calcium nor silicon can be usefully employed alone.—A. G. L.

German Patent.

Cyanogen or ammonium compounds; Process for increasing the yield of —— in blast-furnace work. G. Reininger. Ger. Pat. 167,033, Sept. 16, 1904.

The process consists in introducing an alkaline earth carbide into that part of the furnace where the temperature is about 800°—1000° C.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 546.)

(A.)—ELECTRO-CHEMISTRY.

Ammonium sulphate; Conductivity of —— in mixtures of sulphuric acid and water. G. Boizard. Comptes rend., 1906, **142**, 1082—1084.

When ammonium sulphate is dissolved, *e.g.*, in the proportion of 1 per cent., in solutions of sulphuric acid of different strengths, the conductivity of the acid solution may be increased or diminished, according to the concentration of the acid. The author found that with solutions containing 100—95 per cent. of sulphuric acid, the addition of 1 per cent. of ammonium sulphate increases the conductivity; with acids containing 95—1·8 per cent. of sulphuric acid the conductivity is decreased, whilst with solutions containing 1·8—0 per cent. of sulphuric acid the conductivity is again increased. The effect of increasing the concentration of the ammonium sulphate varies according to the concentration of the sulphuric acid. With liquids containing over 3 per cent. of sulphuric acid an increase in the proportion of ammonium sulphate causes an increased difference in the conductivities. With acids of about 2 per cent. strength a high concentration of the ammonium sulphate may cause an increase of conductivity, whilst low proportions may cause a decrease. In other words, the point of change from solutions of less conductivity to solutions of greater conductivity than the solvent, which point lies at 1·8 per cent. of sulphuric acid when 1 per cent. of ammonium sulphate is added, can be raised by varying the proportion of ammonium sulphate. With rise of temperature in solutions containing 95—25 per cent. of acid, the ratio of the conductivities of solvent and product approaches unity. With acids of lower strength, increase of temperature has the opposite effect. It is noted that a very large number of substances other than ammonium sulphate have a similar effect on the conductivity of sulphuric acid solutions.—J. F. B.

Electro-chemical analysis; A simple form of rotating electrode for ——. F. M. Perkin. XXIII., page 609.

English Patents.

Electrolytic apparatus. G. G. Hepburn, Whitefield, and Mather and Platt, Ltd., Manchester, Lancs. Eng. Pat. 12,221, June 13, 1905.

The electrolytic apparatus described is designed for the use of bleachers in making hypochlorite, and is an adaptation of the "bell-jar" method on a small scale, and for intermittent working. The apparatus consists of a number of cells connected to a hydraulic main for filling and emptying by means of suitable valves and stop-cocks. Each cell may consist of two or more compartments, in each of which is placed an inverted vessel or "bell-jar," and each of which may be separately emptied or placed out of action by means of a siphon. Provision is also made for sweeping out of each cell the residual chlorine left after electrolysis has been stopped.—A. G. L.

Furnaces; Electric ——, *for treating gases by means of electro-magnetically or electro-dynamically actuated electric arcs.* A. J. Petersson, Sweden. Eng. Pat. 9164, April 18, 1906. Under Int. Conv., April 18, 1905.

This invention relates to an electric furnace for treating gases, by means of electric arcs struck between a central electrode and another electrode surrounding it, the arcs being made to rotate around the latter by the action of a magnetic field. The coil and iron core for producing the magnetic field are placed annularly around the reaction chamber. The winding of the coil may consist of a thick ribbon-shaped conductor wound spirally round the reaction chamber, the conductor being supplied with continuous current "of great volume," or with alternating current from a transformer. The primary winding of the latter is connected in series with the arcs, or the innermost turn of the coil may act as the outer annular electrode. Where alternating current is used for creating the magnetic field, the outer annular electrode may have the shape of an open ring. Modifications are described in which the coil surrounding the chamber, and also the pole surfaces of the ring-shaped iron core, have such a shape that the strength of the magnetic field, within the space enclosed by the outer annular electrode, decreases uniformly or approximately uniformly towards the centre. —B. N.

Ozonising atmospheric air; Apparatus for —— [*electrically*]. Ozonair, Ltd. and E. L. Joseph, both of London. Eng. Pat. 4579, Feb. 24, 1906.

This invention relates to a portable self-contained apparatus for ozonising air, and consists of a box divided into two compartments, one of which has its opposite ends open but fitted with wire screens above and below. The electrode structure consists of an open, square, vertical tube of flexible non-conducting material forming the dielectric, this being covered on its outer and inner

surfaces with sheets of wire gauze. The electrodes are mounted in the open compartment so as to leave air passages through the middle of the structure, and also between the electrodes and the sides of the compartment. The structure is secured in position in the box by means of a spider frame, made in two parts, which is inserted and expanded within the electrode structure, and the frame also supports at its centre an electric motor, the latter driving a fan which revolves between one of the wire screens and the corresponding end of the electrode structure. The closed compartment contains a step-up transformer, and upon the cover of this the two switches and connections are mounted for controlling the supply of current to the fan motor and, through the transformer, to the electrodes.—B. N.

United States Patents.

Furnace; Electric ——. J. E. Hewes, Plattsburg, N.Y. Assignor to C. H. Boone, Baltimore, Md. U.S. Pat. 820,574, May 15, 1906.

The hearth of the furnace consists of a series of trough-like plates, abutting against each other, and forming a rectilinear trough. On each side of the hearth are guides with two endless travelling chains or conveyers, travelling over and resting on them, and serving to move the hearth in a longitudinal direction under the electrodes, whereby the smelted materials are conveyed away from the electrodes. Stationary means are provided for feeding the materials to be smelted to the electrodes. One electrode is horizontal, and in line with the hearth and the second electrode, which is placed vertical, the latter being at a higher elevation so as to leave a space below it. A hood surrounds the electrodes and the hearth, and a depending shield fits down into the hearth and around the horizontal electrode, in order to close the hearth, yet permitting the latter to be moved forward.—B. N.

Conductors; Composition of matter for electric ——. W. G. Clark, New York, Assignor to Parker-Clark Electric Co., Jersey City, N.J. U.S. Pat. 821,017, May 22, 1906.

This invention relates to a substance which is a conductor of electricity when cold, and which consists of a dense, non-porous and non-crystalline combination of carbon and silicon less hard than carborundum. It is produced by decomposing gaseous compounds of carbon, in the presence of volatile compounds of silicon, at a temperature below the fusing point of carborundum.—B. N.

Contact substances used for catalytic action; Treating —— [*electrolytically*]. I. Kitsee, Philadelphia, Pa., Assignor to C. L. Hamilton and W. F. Hamilton. U.S. Pat. 821,042, May 22, 1906.

"Contact poisons," such as arsenic, are extracted from contact masses, such as platinum, by making the latter part of the anode in an electrolytic apparatus, and subjecting the mass to the action of the electric current; the contact poison is oxidised, and dissolved out of the mass.—B. N.

[*Calcium carbide*]. *Calcium oxide; Process of reducing* ——. T. L. Willson, New York, Assignor to Union Carbide Co., Va. U.S. Pat. 820,031, May 8, 1906.

An electric arc is established between suitable poles, one of which is the end of a depending carbon electrode. The arc is surrounded by a charge of calcium oxide and carbon in proportions suitable to form calcium carbide; the reduced carbide is accumulated into a mass, and used as one electrode, the arc being maintained by gradually moving the carbon electrode; unreduced portions of the charge are kept in contact with the arc and the electrode, so as to retain the heat of the arc, exclude air, and yet permit the escape of the gases produced by the reaction.—A. G. L.

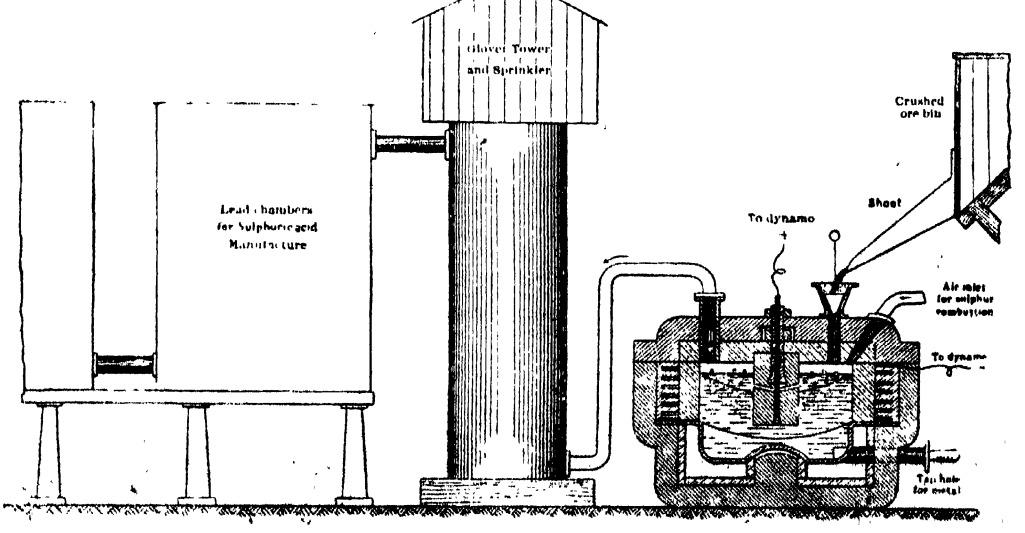
Turpentine; [Electrical] Process of treating wood for the extraction of ——. F. T. Snyder. U.S. Pat. 821,264, May 22, 1906. XIII*B*., page 597.

French Patent.

Incandescent filaments (Vacuum arc lamps); Process of manufacture of ——. A. Franfurther and H. Kuhlmann. First Addition, dated Nov. 13, 1905, to Fr. Pat. 356,999, Aug. 17, 1905. II., page 583.

German Patents.

Alkali compound that can be easily converted into alkali hydroxide or alkali carbonate; Process for the electrolytic manufacture of ——, *and of chlorine*. J. Wunder. Ger. Pat. 165,487, Sept. 14, 1904.



Mixtures of an alkali chloride and silica, free from sulphates, are electrolysed at about the melting temperature of the alkali chloride. The decomposition may be represented by the equation:—

$$6NaCl + 3SiO_2 = \underset{\text{at the cathode}}{Na_2Si} + \underset{\text{at the anode}}{2Na_2SiO_3 + 6Cl};$$

and it is claimed that the whole of the chlorine is obtained in the free state. A mixture of five parts of sodium chloride and two parts of silica is recommended.—A. S.

(B.)—ELECTRO-METALLURGY.

Fused electrolytes; Factory scale experiments with ——. E. A. Ashcroft. Electrochem. Ind., 1906, **4**, 178—180.

The author uses cells provided with means for magnetically rotating the fused bath during electrolysis. For the recovery of zinc from zinc sulphide, the ore is suspended in an electrolyte of fused zinc chloride, and by working at 450° C., the sulphide is resolved into its elements, sulphur distilling off, or being oxidised at the surface of the vat, and molten zinc depositing on the cathode at the bottom of the cell.

The plant as arranged for producing metallic zinc, and sulphuric acid, is illustrated in the figure.

So far as zinc is concerned, the process is not very promising, as most ores contain too much gangue and other impurities to be employed directly. With lead sulphide, electrolysed in a medium of fused zinc chloride or fused lead chloride, good results are obtained.

The reactions of ferrous chloride with lead are of some importance, as offering a method for eliminating iron in the mixed sulphide process. Below 450° C., iron appears to decompose lead chloride: $PbCl_2 + Fe = FeCl_2 + Pb$, but at about 600° C. the reaction is reversed, the iron is reduced, and alloys with the molten lead.

To overcome the difficulty of access to the contents in the cell illustrated above, a modified form has been devised, open at the top. When this is used for the electrolyses of fused chlorides with recovery of chlorine, the gas is drawn off through a tubular anode.—R. S. H.

Electrolysis of fused zinc chloride in cells heated externally. J. L. F. Vogel. Faraday Soc. Trans., May 15, 1906. [Advance proof.]

In 1898, in conjunction with O. J. Steinhart, a series of experiments was commenced with a view to preparing anhydrous zinc chloride, by dissolving oxide of zinc in hydrochloric acid, and subsequently electrolysing the fused salt in cells heated externally, a process suggested by the late F. Maxwell Lyte. At first, great difficulties were encountered in producing anhydrous zinc chloride, the complete dehydration of the salt proving to be very essential for the efficiency of the electrolysis. Finally, this was successfully accomplished by evaporation under a partial vacuum. In a small scale experiment, carried out in 1898 with 10 ampères at 3·3 volts a current efficiency of 93 per cent. was attained. In more recent experiments with a cell of fire-proof stoneware, taking 600 ampères at 4 to 5 volts., the current efficiency worked out at 91·5 per cent. over a period of 10½ days. The temperature of the cell was kept as near 500° C. as possible. The author points out the advantages of external heating, especially in the economy of electric energy, and considers that the field is still open for the commercial production of zinc and chlorine by such a process.—R. S. H.

United States Patent.

Copper; [Electrolytic] Recovery of —— from solutions containing it. B. Combs, Turin, Italy, Assignor to E. Casper, London. U.S. Pat. 820,555, May 15, 1906.

See Eng. Pat. 20,657 of 1902; this J., 1903, 1136.—T. F. B.

French Patent.

Sodium; Electrical conductor of metallic ——. A. G. Betts. Fr. Pat. 361,102, Dec. 19, 1905.

The conductor consists of metallic sodium protected from the air by a casing of copper or other metal. On account of the high coefficient of expansion of sodium, the conductors are best made in sections, several methods of joining these together being described. Since the specific gravity of copper is nine times that of sodium, whilst its electrical conductivity is only three times as high, it is claimed that a sodium conductor will carry as much current as a copper one three times its weight.—A. G. L.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

Lipolytic enzymes in higher fungi. J. Zellner. Monatsh. f. Chem., 1906, **27**, 295—304.

From the results obtained with nine representative species the author concludes that the fats in the higher fungi contain a large proportion of free fatty acids. These can be detected even in the fats of the fresh fungi, and their amount increases on drying and keeping the fungi. As much as 80 per cent. of the fats may be hydrolysed, but complete hydrolysis has not yet been observed. In many cases it is possible to effect the hydrolysis of other fats by means of the powdered fungus. This was notably the case with *Lycoperdon gemmatum*, *Boletus elegans*, *Galerrheus vellereus*, and *Lepiota procera*, whilst *Cantharellus cibarius*, *Polyporus confluens*, and *Hydnum repandum* were almost without action upon rape oil. The hydrolysis is promoted by gentle heat (40° to 45° C.), and is checked by heating the fungus powder to 110° C., or by the addition of mercuric chloride. No enzyme could be isolated from the fungi.—C. A. M.

Service berry [Sorbus aucuparia]; Seeds and oil of the ——. L. van Itallie and C. H. Nieuwland. Arch. Pharm., 1906, **244**, 164.

The seeds of *Sorbus aucuparia* contain 21·9 per cent. of a fatty oil which can be extracted with petroleum ether. The seeds, freed from oil, gave the following results on analysis:—Water, 9·2; nitrogen, 5·44; albumin (nitrogen × 6·25), 34·0; cellulose, 13·2; ash, 5·21; carbohydrate (calculated as glucose), 24·2 per cent. The oil is a sweet-tasting, mobile, slightly yellowish liquid, which rapidly dries on exposure. It possesses the following constants:—Sp. gr. at 15° C., 0·9317; refractive index at 15° C., 1·4753; acid value, 2·35; saponification value, 208·0; iodine value, 128·5; iodine value of the fatty acids, 137·5; acid value of the fatty acids, 230·2. Ten grms. of the seeds, freed from oil, gave 7·29 mgrms. of hydrocyanic acid.—F. Shdn.

Camels' butter; Analytical values of ——. J. Vamvakas. Ann. chim. anal., 1905, **10**. 350. Z. Untersuch. Nahr.- u. Genussm., 1906, **11**, 630.

A specimen of camels' butter from Tripoli was of firm consistency, and had a light grey colour and a characteristic odour. The fat gave the following results:—M. pt., 38° C.; m. pt. of fatty acids, 47° C.; volatile fatty acids, 8·6 per cent.; insoluble fatty acids, 88·29 per cent.; saponification value, 208·0; iodine value, 55·1; and refractometer reading, 20.—C. A. M.

Elaidin and Elaidic Acid. Gawalowski. Pharm. Post., 1905, **38**, 97—98. Z. Untersuch. Nahr.- u. Genussm., 1906, **11**, 622—623.

A commercial specimen of oleic acid, which melted at 30·7° C. and contained 4 per cent. of unsaponifiable matter, yielded on treatment with mercury and nitric acid, an elaidic acid which consisted of a mixture of a crystalline and a liquid product. The oily portion was nearly colourless and had a not unpleasant odour. The solid portion gave the following analytical values:—Sp. gr., 0·930; m.pt., 38° C.; solidification point, 23·0° C., and unsaponifiable matter, 0·3 per cent. It yielded a hard white soap. The liquid portion melted at 16·5° C., and solidified at 14·9° C. It had a sp. gr. of 0·936, and contained 16·2 per cent. of unsaponifiable matter. It solidified after standing for some days at 15° C. In the author's opinion two distinct acids, stearo-elaidic and oleo-elaidic acids, are formed in the elaidin reaction.—C. A. M.

Fats; Action of iron and manganese salts in producing rancidity of ——. P. F. Dalezki. Russi Wratsch., 1904, **3**, 752. Z. Untersuch. Nahr.- u. Genussm., 1906, **11**, 625—626.

Experiments were made with butter fat, cacao butter, and almond oil, freed from proteids and other impurities. Precautions were taken to exclude any bacterial action, air, light, and heat being the only factors in addition to the iron or manganese stearate. These salts were nearly

insoluble in cold almond oil, and in the fats at their melting points. In the experiments the admixture was made on the water-bath. It was found that both salts increased the oxidation process, the influence of manganese being greater than that of iron. The salts that had dissolved in the fats had a greater oxidising effect than the undissolved salts. The action was judged to be purely catalytic, the salts acting as conveyors of the atmospheric oxygen. The process of oxidation appeared to follow a somewhat different course with manganese than with iron. It proceeded more slowly at first, whilst heat accelerated the oxidation. When kept at the ordinary temperature with the admission of light and air, the fats became rancid, the iodine value decreasing, and the acid, saponification, and Reichert-Meissl values increasing. In the case of cows' butter, however, the last value remained almost constant.—C. A. M.

Cholesterol; Halogen derivatives of ——. J. Mauthner. XXIV., page 611.

Soap in Turkey. Oil, Paint and Drug Reporter, May 21, 1906. [T.R.]

According to the new regulations, which are based upon a report received from the faculty of the Imperial College of Medicine, the maximum percentage of solids (salt, soda and earthy matters) allowed in soap is 2 per cent., and of water 4 per cent. Soaps in which these percentages are exceeded are regarded as adulterated, and the manufacturers are liable to prosecution. The manufacture of soaps containing sodium silicate is forbidden. Merchants selling wares coming within the above prohibition are liable to prosecution for the sale of an adulterated article. Considerable trouble has been caused of late years to importers of soap into Turkey on account of the rigid requirements in regard to the chemical analysis of the goods before they are liberated from the customs. Three consignments of well-known brands of English soap were held for a long period, on the ground that the proportion of caustic soda exceeded 0·5 per cent., and that talc was present.

Turkey produces most of the common grades of soap required for ordinary consumption, but there is a considerable importation of the finer qualities, chiefly from Great Britain and France, and to some extent also from Italy and Germany. These importations at Smyrna reach an annual figure of about 315 tons. There is a large exportation from this section of cheap grades of soap made from olive oil, in which American purchasers are taking a steadily increasing share. An important market for this exportation has just been closed by the recent decree of the Bulgarian Government shutting out the soaps of this region on the ground that they are manufactured from materials of foreign origin.

The reason for the small imports of soap into Arabia is that the natives use a strong alkali substitute called "hootum." This is derived from an evergreen shrub growing plentifully on the desert, and called "shagar" by the Arabs. It is burned and the residual ash is incorporated with black mud into lumps. The prevailing use of this alkali explains why only 3,854 lb. of soap were imported into Aden last year, nearly all of it from France.

Fish oil industry; Japanese ——. Oil, Paint and Drug Reporter, May 14, 1906. [T. R.]

After boiling, the fish are put into wooden presses about 3 ft. square and 2½ ft. deep, the sides and bottom of which are composed of slats having a small opening between them. The cover is put on, and pressure is exerted by means of levers or stones put on top of the cover, the oil and water pressed from the fish running into a tank, where the water, going to the bottom, is first drawn off, and the oil afterward put into cans, soldered up, and is then ready for shipment.

The fish, after being pressed, is in the shape of a hard sodden mass, which is removed from the press, broken into small pieces, and spread out on mats in the sun and dried. When dry it is packed in straw mats, and shipped. It is estimated that not more than 60 per cent. of the oil is extracted from the fish, while in drying the manure, more than half of the phosphates, the most valuable part, are lost.

The oil is nearly all exported to Holland and England, but the manure is all used in Japan, and the amount annually produced is not sufficient to supply the demand.

Olive oil. U.S. Customs Decisions. [T. R.]

The following decisions on olive oil have been issued by the Treasury Department:—

(1) Mere presence or absence of free fatty acids in olive oil does not determine whether or not such oil is fit for use as an article of human food. Rancidity may exist in such oil before the formation of free fatty acids, and such acids may exist long before the oil becomes rancid.

(2) Olive oil in condition to be filtered, and blended with cottonseed oil, and when so blended fit to be used as an article of human food, is dutiable at the rate of 40 cents per gall., under the provisions of paragraph 40 of the tariff.

English Patents.

Bones, skins, &c.; Treatment of various substances such as —— for obtaining useful products [Grease, glue, and manure] therefrom. J. Harger. Eng. Pat. 9779, May 9, 1905. XIV., page 597.

Soap and detergent compounds; Manufacture of ——. H. J. Armstrong, M. R. Armstrong, both of Ashton on Ribble, and H. H. Armstrong, Penwortham. Eng. Pat. 16,406, Aug. 12, 1905.

Claim is made for the incorporation with the soap of carbon tetrachloride, either by itself, or together with hydrocarbon solvents. The carbon tetrachloride may be mixed with fatty acids before saponification with alkali, or it may be incorporated with the still fluid soap-mass obtained from fixed oils, whilst volatilisation may be prevented by carrying out the process in covered vessels. Detergent preparations are obtained by pulverising a soap containing carbon tetrachloride with a suitable quantity of sodium carbonate.—C. A. M.

French Patent.

Soap; Manufacture of a dry —— *from colophony and soda [for paper-sizing].* M. Douxami. Fr. Pat. 361,154, Dec. 29, 1905.

Colophony (100 parts) is melted and treated, little by little, with sodium carbonate (20 to 25 parts), and the mixture, which contains a slight excess of alkali, heated and stirred until nearly solid.—C. A. M.

German Patent.

Sulphide ores; Economical treatment of —— *[for white lead].* C. B. Jackes. J. Canadian Min. Inst., 1905, 8, 244—258.

The author proposes to apply Kingsley's white lead process (Eng. Pat. 23,909; this J., 1905, 681) to the enormous sulphide deposits of Canada which cannot profitably be worked in the ordinary way on account of their remoteness from smelting works. Briefly, the method consists in acting on the concentrated galena with 30 per cent. nitric acid containing some nitrous acid, at a temperature of 80° C., lead nitrate, sulphur, and nitric oxide being formed. The last is oxidised by air to nitrogen peroxide, which, in presence of air and water, again yields nitric

acid containing nitrous acid, and is used over again. The solution of lead nitrate is run off from the sulphur and gangue, freed from iron by adding a little basic lead carbonate (white lead), and then precipitated by a mixture of caustic soda and sodium carbonate, white lead and sodium nitrate being formed. From the latter, the nitric acid is recovered by acting on it with sulphuric acid formed from the sulphur liberated in the first stage of the process, the nitric acid being distilled off, and condensed in pipes which serve to heat the mixture of ore and acid to the proper temperature. Apart from losses in working, the whole of the nitric acid used is thus recovered.—A. G. L.

UNITED STATES PATENT.

Turpentine; [Electrical] Process of treating wood for the extraction of ——. F. T. Snyder, Oak Park, Ill. U.S. Pat. 821,264, May 22, 1906.

THE wood is enclosed in a vessel, having air-tight sides and top, and the vessel is inserted in a furnace, also provided with air-tight sides and top, through an opening in the bottom of the furnace. Heat is developed electrically in the interior of the latter, sufficient to produce destructive distillation of the wood, and the vapours, containing turpentine, are drawn off through the bottom of the vessel, and collected. The vessel, containing the remaining charcoal, is removed through the bottom of the furnace, the vessel being maintained in an upright position so as to prevent the escape of the heated vapours and consequent admission of air. Another vessel containing wood for treatment is placed in the furnace, the heat of the latter being thus maintained, and the charcoal is removed in a heated condition without damage by the external air; the charcoal is subsequently cooled apart from the furnace and out of contact with air.—B. N.

(*C.*)—INDIA-RUBBER, ETC.

Balata; Reactions of ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 844.

WHEN the pure hydrocarbon of balata is subjected to prolonged treatment with chlorine in chloroform solution, and the resulting product reprecipitated several times from benzene solution, a white, microcrystalline body is obtained which answers to the formula $C_{10}H_{12}Cl_6$. It is soluble with difficulty in benzene, and is not attacked by concentrated nitric acid. By dissolving balata hydrocarbon in fuming nitric acid, precipitating with water, and reprecipitating the product several times with ether from acetone solution, a yellow amorphous body of an acid nature is obtained, which contains 53·17 per cent. of carbon, 6·46 per cent. of hydrogen, and 8·59 per cent. of nitrogen. (See also Caspari, this J., 1905, 1274.)—W. A. C.

India-rubber; Influence of light magnesia as a filling material upon ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 816.

FIVE experimental mixings of Para rubber with 10 per cent. of sulphur and rising percentages of light magnesia were vulcanised and tested as before (this J., 1906, 487). Both strength and elasticity are greatly enhanced by 25 per cent. of light magnesia, the former more than 10 times and the latter about 2½ times, as compared with a blank experiment. The increase, up to 25 per cent. of admixture, is quite steady.—W. A. C.

Rubber; Methods of colouring ——. E. W. Lewis. J. Soc. Dyers and Col., 1906, **22**, 184—187.

THE following methods are considered in detail: (1) The incorporation of coloured pigments with the rubber mass during the ordinary process of mixing, either dry or in the presence of solvents, (2) the staining of vulcanised rubber goods subsequent to curing, by means of soluble colours, and (3) the admixture of colours, soluble in the ordinary solvents of rubber, with rubber solutions intended for use in the preparation of dipped or spread goods.—D. B.

Ebonite; Analysis of ——. R. Thal. XXIII., page 610.

Tanning materials; Duty-free importation of ——, *into Germany.* Board of Trade J., May 31, 1905. [T.R.]

THE Bundesrath has authorised the duty-free importation, under the conditions governing "improvement" trade, of quebracho and other tanning woods, and of tanning materials generally, destined either to be cut up in small pieces, and re-exported, or for use in the manufacture of tanning or colouring extracts for exportation.

ENGLISH PATENT.

Bones, skins, &c.; Treatment of various substances such as ——, *for obtaining useful products [Grease, glue, and manure] therefrom.* J. Harger, Market Harborough. Eng. Pat. 9779, May 9, 1905.

THE apparatus employed consists of a horizontal rotating cylinder constructed of perforated metal plates or gauze, mounted upon a central shaft, and surrounded by a fixed cylinder provided with a steam-jacket. The material, such as bones or skins, is placed in the inner cylinder, a manhole being provided for the purpose, and the space between the two cylinders is about one-third filled with benzene. Steam is then turned into the steam-jacket until the benzene boils, the inner cylinder being slowly rotated. The benzene vapours pass out of the cylinder, and are condensed in a separate apparatus, fresh quantities of the solvent being introduced as required. When the bones have been freed from grease, the solvent containing the oil is run off, and all the benzene removed by the introduction of a current of steam. Manholes in the outer cylinder are now opened, and air is allowed to pass through the cylinders, the inner one being rotated so that all dirt, meat, &c., is rubbed off, and falling through the gauze, is removed by brushes affixed to the outer part of the inner cylinder. The bones are then subjected to the action of steam and water to remove gelatinous

substances, and are afterwards dried by reducing the pressure in the cylinders. The inner cylinder is finally rotated rapidly until the bones are sufficiently disintegrated to pass through the gauze and a perforated plate fixed in the manhole of the outer cylinder.—W. P. S.

Tanning and colouring materials; Automatic extractor for ——. L. F. Jury. First Addition, dated Dec. 19, 1905, to Fr. Pat. 358,783, Oct. 7, 1905.

IN this addition, the ball-floats which are provided in the original specification (this J., 1905, 327), for the automatic control of the admission of liquors into the various tanks, are replaced by shafts carrying cams, which are placed in positions so that they open, at the right moment, sluice valves situated either in the diffuser or in the liquor reservoirs.—J. F. B.

GERMAN PATENT.

Gelatin; Process of hardening objects of ——, *so that they retain their shape.* H. Rumpel. Ger. Pat. 167,318, Oct. 16, 1904.

GELATIN objects can be permanently hardened by the action of formaldehyde, acrolein, and chromium compounds, dissolved in alcohol, acetone, or ether.—T. F. B.

XV.—MANURES, Etc.

(*Continued from page* 549.)

Over-limed soil; Regeneration of ——. S. Maki and S. Tanaka. Bull. Coll. Agric., Tokyo, 1906, **7**, 61—65.

IT has been shown previously, that in order to obtain the best yield of plants, a certain ratio of available lime to magnesia is necessary. In the case of cereals, the proportion of magnesia should be equal to that of lime, if the former be present as magnesite, which is similar to the lime compounds present in most soils in its behaviour to solvents. The authors have examined the action of magnesium sulphate, which is much more readily available than magnesite, in restoring the efficacy of over-limed soils. It was found that on both sandy and loamy soils, 14 parts of crystallised magnesium sulphate have the same effect as 100 parts of magnesite.—A. S.

Manure; Influence of the reaction of —— *upon the yield.* K. Aso and R. Bahadur. Bull. Coll. Agric., Tokyo, 1906, **7**, 39—46.

WAGNER has shown that a mixture of superphosphate with ammonium sulphate, which latter is physiologically acid, does not give good results unless some calcium carbonate is applied to counteract the evil effect of the acid reaction on the roots of the plants. The authors have compared the effects of the (neutral) disodium phosphate with the (acid) monosodium phosphate, and with calcium superphosphate in presence of ammonium sulphate (physiologically acid) and of sodium nitrate (physiologically alkaline). Experiments with peas and barley showed that the combination of several acid manures or of several alkaline manures does not lead to good results, but that a mixture of acid and alkaline salts acts beneficially on the yield. The best results with sand cultures of barley and peas were obtained with a mixture of sodium nitrate and monosodium phosphate, whilst in the case of paddy-rice, a mixture of ammonium sulphate and disodium phosphate proved the most satisfactory. In experiments with soil cultures of onions, ammonium sulphate, in the presence of disodium phosphate and potassium carbonate, yielded a far better result than sodium nitrate, and the results also confirmed the observations of other investigators, that ammonia under suitable conditions is as efficacious as nitrate, and that nitrification is not necessary. The general conclusion drawn by the authors is that small changes in the reaction of the manure have often a much greater influence on the yield than might be presumed, and that the effects differ with different crops.—A. S.

Calcium cyanamide; Efficacy of ——, *[as fertiliser] under different conditions.* R. Inamura. Bull. Coll. Agric., Tokyo, 1906, **7**, 53—55.

CALCIUM cyanamide is an alkaline manure since, on decomposition in the soil, it yields calcium carbonate and ammonia, the latter in turn being soon transformed into ammonium carbonate. As ammonium sulphate, though of neutral reaction, is physiologically acid, it appeared probable that the most suitable conditions for obtaining satisfactory results would be different with the two compounds, and accordingly the efficacy of mixtures of calcium cyanamide with the acid double superphosphate and the neutral disodium phosphate respectively, was determined. The best results were obtained with the superphosphate mixtures, whereas in the case of ammonium sulphate, the neutral disodium phosphate mixtures are superior to those containing double superphosphate (see preceding abstract).—A. S.

Calcium cyanamide; Manurial value of ——. K. Aso. Bull. Coll. Agric., Tokyo, 1906, **7**, 47—52.

COMPARATIVE experiments on rice ("upland" and "paddy"), sesamum, and hemp with calcium cyanamide (19·2 per cent. of nitrogen), Chili saltpetre, and ammonium sulphate, showed that in general the cyanamide gave rather better results than equivalent quantities of the sodium nitrate and ammonium sulphate. The only unsatisfactory result with cyanamide was in the case of paddy rice on a soil rich in humus, and of a similar character to moor soils, which have been shown by Tacke and Feilitzen not to yield such satisfactory results with calcium cyanamide as other soils do.—A. S.

Potassium compounds; Manurial value of different —— *for barley and rice.* K. Aso. Bull. Coll. Agric., Tokyo, 1906, **7**, 67—72.

THE author has compared the manurial effect of four potassium compounds—the carbonate, sulphate, chloride, and silicate—in three consecutive years on barley and paddy rice. Potassium chloride was found to accelerate the flowering process and increase the grain production, giving the highest quotient of yield, in the case of barley; but with rice it caused a decrease in the yield. In several cases with rice plants, potassium silicate proved to be the most efficacious of the four compounds. Potassium sulphate favoured the production of straw rather than of grain. Potassium carbonate was inferior to sulphate in all cases, when applied together with disodium phosphate, a physiologically alkaline manure.—A. S.

Silica; Function of —— *in the nutrition of cereals.* A. D. Hall and C. G. T. Morison. Roy. Soc. Proc., 1906, **77B.**, 455—477.

EXPERIMENTS extending over a series of years show that whilst silica is not an essential constituent of plant food, it may play a definite part in the nutrition of cereal plants, such as barley, which contain normally a considerable proportion of silica in their ash. A free supply of soluble silica (sodium silicate) causes an increased and earlier formation of grain, and thus acts in a similar manner to phosphoric acid. The effect of the silica is not a direct one, but is due to an increased assimilation of phosphoric acid by the plant. Apparently, the silica within the plant does not cause a more complete utilisation of the phosphoric acid that has already been assimilated, or promote the migration of food materials from the straw to the grain, but it gives the plant such a stimulus that more vigorous development and an increased assimilation of the phosphoric acid contained in the soil are possible. The results of water cultures of barley, and direct experiments on the effect of sodium silicate on the constituents of the soil, show that the silicate has no chemical action on the soil phosphates.—A. S.

Beetroots; Substitution of soda for potash in the ash of ——. J. Urban. XVI., below.

Superphosphates; Determination of the soluble and total phosphoric acid in ——. K. Rohm. Chem.-Zeit., 1906, 30, 542—543.

A COMPARISON of the digestion and agitation methods of determining the soluble phosphoric acid shows the latter to give higher and more constant results, especially when the agitator is run at a speed of 32—40 revolutions per minute, the differences in that case being only 0·04—0·08 per cent. of phosphorus pentoxide. In the determination of the total acid, the three methods generally used for dissociation (namely, nitrohydrochloric acid, nitric acid, or nitric and sulphuric acids) gave very concordant results, whereas results obtained with hydrochloric acid (tried for comparison) came out too low and irregular. Where no stirring apparatus is available, it is essential that the precipitate should be left for 24 hours to subside, before filtering, owing to the irregularity in the results otherwise obtained.—C. S.

ENGLISH PATENTS.

Bones, skins, &c.; Treatment of various substances such as ——, *for obtaining useful products [Grease, glue, and manure] therefrom.* J. Harger. Eng. Pat. 9779, May 9, 1905. XIV., page 597.

Fertiliser; Manufacture of a ——. R. Hooton and J. Noble, both of Ashton-under-Lyne. Eng. Pat. 10,733A, May 23, 1905.

CLAIM is made for the use of the residue left in the retort on carbonising cottonseed husks or the like, either by itself or with the addition of substances containing phosphates. A substance such as oil or resinous waste may be mixed with the husks prior to carbonisation to render the residue cohesive.—C. A. M.

XVI.—SUGAR, STARCH, GUM, Etc.

(*Continued from page* 550.)

Beetroots; Substitution of soda for potash in the ash of ——. J. Urban. Z. Zuckerind. Böhmen., 1906, 30, 397—402.

THE author has examined some beetroot plants grown in a sandy-humus soil manured only with Chili saltpetre. These beets showed an abnormally large development of the green organs, the weight of which was double that of the root, whereas in normal beets the ratio is reversed. The colour of the foliage of these abnormal beets was exceptionally dark green. The author concludes that the composition of the ash, both of the roots and the green portions, is liable to change according to the soil, fertilisation, and other conditions. In the case of the abnormally developed beets the plants had taken up a very high proportion of sodium salts, the quantity of which considerably exceeded that of the potash; at the same time the quantity of total alkali was approximately the same as in normal beets. But although the soda can thus replace an equal amount of potash in the composition of the plant, it was established that the former alkali is not equivalent to the latter so far as the sugar-producing value is concerned. The author shows that the most favourable condition for sugar-production exists when the ratio of potash (K_2O) to nitrogen is about 1:1. The peculiar characters noted in the abnormal beets mentioned above, are attributed to a great preponderance of nitrogen over potash, the ratio of K_2O to N being 1:3·1. —J. F. B.

Sugar beet; Growth of ——, *in Germany during* 1905. Hollrung. Zeit. Ver. deut. Zuckerind., 1906, 446—451.

FOLLOWING the dry weather of 1904, the year 1905 was characterised by low temperature and much rain. The cold, dry April weather was most unfavourable for the sprouting of the beet, which requires at this stage moisture and a free supply of warm air; factors which can, to some extent, be supplied in bad years by ensuring a loose, moist soil. On the whole, the roots were free during the year from any very serious animal or vegetable pests; those observed are mentioned in detail in the paper. In East Germany, there was a marked growth of the beetroots above the surface of the soil due to the dryness and hardness of the ground a short depth below the surface, which prevented the roots from piercing downwards, so that growth forced them out of the ground. Owing to the prevalence of disease among cattle fed on the green leaves of the beet, these leaves were examined for poisonous fungi without such being found. The disease, inflammation of the bowels, is probably due to the fact that a lack of sunshine prevailing, the soluble and deleterious potassium oxalate of the unripe leaves has not been converted into the insoluble and harmless calcium oxalates which occurs in the ripening process. The paper concludes with a series of mechanical analyses of soils from sugar beet farms.—E. F. A.

Sugar beet; Influence of environment on the composition of ——. H. Wiley. U.S. Dept. of Agriculture, Bureau of Chemistry, Bulletin No. 96, 1905.

THIS is a summary of work extending over the five seasons 1900—1904. During this period, a number of experimental stations have collaborated to collect data bearing on the influence of environment on the sugar content of the beet, in order to determine the average potency of such factors as latitude, temperature, rainfall, &c.

Preliminary reports have been issued each year. The same seed—of the Kleinwanzlebener variety—was furnished to each station. Determinations have been made of the yield per acre, percentage of sugar in the beet, and purity coefficient; also of the mean temperature, rainfall, number of clear days, and sunshine. The results are given in tabular form, and also plotted graphically. In spite of many minor modifying circumstances, it has been possible to determine with considerable accuracy the effect of the major features of environment on the composition of the beet.

As a whole, the observations show that latitude, or, in other words, temperature, is the most potent element of the environment in the production of a beet rich in sugar. "As the temperature rises, the proportion of sugar falls." There appears to be but little relation between the percentage of sunshine and the amount of sugar, but the curve for the length of day, which of course is only a function of the latitude, shows a very close correspondence to that for the sugar content, an increase in the hours of daylight corresponding to a larger yield. The influence of this last factor, however, is somewhat modified by the influence of altitude, which affects very materially the sugar without altering the length of day. It is difficult to trace accurately the influence of altitude, but the observations indicate the tendency of the high altitude to compensate for low latitude, and so increase the sugar.

In considering the apparent relationship shown between the total rainfall and the sugar, it must be remembered that the distribution of the rainfall over the year is quite as important a factor as the total fall. The results indicate that the total fall is really greater than the crop would require, if it could be distributed evenly and at the proper times. The rainfall in reality only incidentally affects the amount of sugar in the beet, its great function being related to the magnitude of the crop.

It is an interesting fact that "a small yield, or small sized beets tends to increase abnormally the percentage of sugar in the beet." This, the author states, is due to the fact that the beet has acquired, as the result of long continued selection, a habit of producing sugar, which it exercises even under the most adverse circumstances. The storage room in the small beet being less than in the

large, it becomes more fully charged with the abnormal amount of sugar produced.

For this reason, a deficiency in the rainfall, such as to cause a small crop of undersized beets, has incidentally a tendency to increase the percentage of sugar, whereas an abundant and well-distributed rainfall, by supplying the conditions to grow a beet of abnormal size, will have the opposite effect of diminishing the percentage of sugar in the beet. The same relations govern any direct effect that soil may have on the sugar. An excess of plant food will tend to produce an overgrowth and diminish the sugar content and *vice versa*.

The total changes induced by the rainfall may determine whether or no favourable economic results will be obtained; special interest, therefore, attaches to the experiment on irrigated lands, inasmuch as the control by irrigation of the distribution of water renders the production of a crop practically certain.

Lastly, the experiments bring out in a most convincing manner, that the purity of the juice increases as the proportion of sugar rises.—E. F. A.

Sugar; Storage of beet ——. A. Vermehren. Z. Ver. deut. Zuckerind., 1906, 513—517.

The author has examined from time to time three specimens of sugar stored for a year under proper conditions. Of the specimens, No. 1 was a very dark coloured sugar already a year old, whilst Nos. 2 and 3 were low-grade sugars containing a good deal of calcium salts, and with an acid reaction towards phenolphthalein. After a year, all the sugars had kept excellently: in No. 1, the quotient of purity remained unaltered, and the sample retained its alkalinity towards phenolphthalein. The cupric-reducing power had increased considerably unless the solution tested was precipitated previously with lead acetate; this increase is attributed to the dark colouring matter of the sugar. In No. 2, there was a fall of 0·45 in the quotient of purity, but practically no difference otherwise in spite of the fact that the sugar had an acid reaction when stored; the acidity had only slightly increased, whilst the alkalinity to rosolic acid, though decreasing, was maintained almost to the end. The third sample behaved in a similar manner.—E. F. A.

Lime in sulphited sugar products; Determination [Soap test] of ——. J. de Grobert. Bull. Assoc. Chim. Sucr. Dist., 1906, **23**, 1100—1102.

The determination of lime in the filtered juices from the carbonating process is frequently made by the soap test as employed for the determination of hardness in water. In testing sulphited juices in this manner, it often appears as if the quantity of calcium salts in solution had risen to almost double the value found before sulphitation. Control determinations of the lime as calcium oxalate, show that this apparent increase is really an error, due to the action of the constituents of the sulphited juice on the soap solution. The alkali sulphites in the juice are dissociated on heating, so that a juice which is distinctly alkaline to litmus when hot, may be acid when cold, and therefore capable of decomposing soap. Normal results can be obtained by adding acetic acid to the sulphited juice until it is slightly acid to litmus, and then adding dilute ammonia until the reaction is slightly alkaline.

It is remarked that under normal conditions the soap test always yields rather lower values for lime than the real values determined as calcium oxalate, and that the results require correction by a coefficient which can be established in each particular factory.—J. F. B.

Cane-molasses; Decolorisation [by hypochlorite] of —— for analysis. H. Pellet and C. Fribourg. Bull. Assoc. Chim. Sucr. Dist., 1906, **23**, 1128—1139.

The authors have subjected the process of decolorising sugar solutions and cane molasses by means of calcium hypochlorite to an exhaustive critical study. They find that it is preferable to employ normal lead acetate for defecation in conjunction with the solution of bleaching powder. These reagents when used either separately or together, have no influence on the direct polarisation of the liquid, even in the case of molasses rich in reducing sugars. The hypochlorite when used alone, sensibly increases the lævo-rotation of the solution after inversion for the Clerget test. This action, however, is gradually neutralised by the addition of normal lead acetate, so that when the reagents are used in approximately equal proportions, the polarisation of the inverted acid solution is the same as that of a similar solution without reagents.

In another series of experiments, the authors show that sodium hyposulphite (hydrosulphite) has no useful decolorising effect on solutions of molasses for analysis.—J. F. B.

Molasses; Recovery of sugar from ——. *Utilisation of the "Schleudersalz" [Strontium hydroxide] for washing the saccharate.* K. Andrlik. Z. Zuckerind. Böhmen., 1906, **30**, 402—405.

"Schleudersalz" is the strontium hydroxide which crystallises out when the insoluble strontium "bisaccharate" is decomposed by treatment in the cold, with the production of the soluble "monosaccharate." The utilisation of a hot solution of this strontia, either for the treatment of fresh molasses, or for washing the crude precipitate of strontium "bisaccharate," is rendered very difficult by the fact that the filtration of its solutions is extraordinarily slow. This difficulty has been supposed to be due to the presence of viscous substances, but the author considers that it is caused by the very fine slimy precipitate which is suspended in the solutions, and which clogs the filters. The precipitate is composed mainly of strontium "bisaccharate," strontium carbonate, and calcium carbonate. When the "Schleudersalz" is dissolved, sucrose and raffinose are present, both in the filtrate and in the precipitate, but mainly in the latter. The simplest way of clarifying solutions of "Schleudersalz" is by decantation, for which purpose a pair of settling tanks should be provided above the "bisaccharate" filters. One part of salt dissolved in 5—6 parts of hot water yields a sediment in a quarter of an hour which occupies about one-tenth of the total volume. The clear liquid, containing 15—16 per cent. of $Sr(OH)_2 + 8aq.$, can then be used with perfectly satisfactory results for washing the crude precipitate of strontium "bisaccharate," whilst the sediment can be added to the washed "bisaccharate," and treated with it in the cold chamber.—J. F. B.

Raffinose; Hydrolysis of —— by citric acid. J. Piersaerts. Bull. Assoc. Chim. Sucr. Dist., 1906, **23**, 1143—1146.

The regulated hydrolysis of raffinose by acids yields a mixture of lævulose and melibiose, the specific rotatory power of the products being, according to several observers, $[\alpha]_D^{20^\circ} = 53{\cdot}0^\circ—53{\cdot}5^\circ$. The complete hydrolysis of raffinose requires a much more profound attack, and cannot be effected by acids in a quantitative manner owing to the destruction of the lævulose, and the formation of reversion products. The author has studied the hydrolysis of raffinose by citric acid under the following conditions:—50 c.c. of a 5 per cent. solution of raffinose and 10 c.c. of a 20 per cent. solution of citric acid were heated under a reflux condenser in a round-bottomed flask of 250 c.c. capacity. The specific rotatory power decreased as the time of ebullition was prolonged, from 56° after seven minutes to 43·2° after three hours, at the end of which time the liquid had become yellow owing to the decomposition products of the lævulose. It was observed, however, that there is a period of ebullition, lasting from 10 to 30 minutes, during which the specific rotatory power of the solution remains practically constant between 53·8° and 53·0°, corresponding to a quantitative resolution into lævulose and melibiose. Longer heating with acid of the above concentration, or shorter heating with more concentrated acid caused a partial hydrolysis of the melibiose, increasing with the time. The latitude afforded under the conditions described above is more than sufficient for analytical purposes, and no destruction of the lævulose was perceptible until long after the melibiose stage of hydrolysis had been reached.—J. F. B.

Starch; Process for producing an improved ——. F. Drittler, Rutherford, N.J., U.S.A. Eng. Pat. 7705, March 30, 1905.

ONE hundred parts of dry corn-starch are treated with about 80 parts by weight of a liquid hydrocarbon, and thoroughly mixed. By the term "hydrocarbon" the patentee includes paraffins, olefines, compounds of the benzene series, and some of their substitution products, and, by preference, employs carbon tetrachloride or a mixture of the same with crude paraffin oil. From 40 to 50 parts by weight of sodium hydroxide solution (30° B.) are then added to the starchy mixture when a voluminous dry powder is obtained. From this the hydrocarbon may be removed by evaporation, and the alkali may be neutralised by the addition of a suitable quantity of acetic, tartaric, citric, or other organic acid. The resulting product, either alkaline or neutral, retains the unbroken epidermis of the original starch grains, and is capable of swelling in cold water.—W. P. S.

UNITED STATES PATENT.

Massecuite or syrup; Process of purifying ——. M. Weinrich, Yonkers, N.Y. U.S. Pat. 822,171, May 29, 1906.

XVII.—BREWING, WINES, SPIRITS, Etc.

(*Continued from page* 553.)

Barley; Different diastatic capacities of malt from large-corned and small-corned varieties of ——. G. Ellrodt. Woch. f. Brau., 1906, 23, 243—244.

SINCE the number of embryos in a given weight of a small-corned barley is very much greater than in the same weight of a large-corned barley, and since the diastase is secreted by the embryo, it follows that small-corned malts are far richer in diastase than large ones, and that the former are more suitable for distilleries, where malt is used mainly for conversion purposes, whilst the latter are more suitable for breweries, where the extract of the malt is the chief factor. Haymann has experimented with two types of barley containing approximately the same percentage of nitrogen. The large-corned barley had a weight per 1000 corns of 44·9 grms., and a germinative power of 96 per cent., whilst the small-corned barley had a weight per 1000 corns of 29·5 grms., and a germinative power of only 87 per cent. Both barleys were steeped and germinated under identical conditions, and the diastatic powers were determined at different stages of the growth with the following results:—

Age of green malt.	Diastatic units per 100 grms.	
	Large-corned barley.	Small-corned barley.
days.		
1	120	162
3	195	183
5	356	386
7	485	603
8	502	739

Taking the price of the large-corned brewing barley at 15 marks per 100 kilos. and that of the small-corned distillery barley at 12 marks, it is calculated that the unit of diastase costs double as much in the large-corned malt as in the small-corned malt, and, consequently, the choice of the latter for distillery purposes is justified in spite of its lower germinative capacity.—J. F. B.

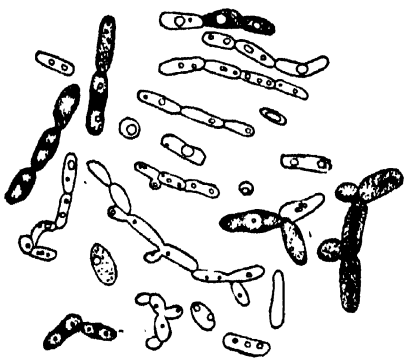
Malt; Sterilisation of ——. J. E. Brauer. Chem.-Zeit., 1906, 30, 529—530.

THE author recommends "bacillol," a product prepared by dissolving tar-oil in soap solution, and containing about 52 per cent. of cresols, as a disinfectant for malt, and states it to be capable of killing all fungi and bacteria without either interfering with the growth of the grain and activity of the diastase, or importing any taste or odour to the mash. After preliminary steeping of the malt for three hours with water, and subsequent washing, the grain is soaked for three hours with a $\frac{1}{4}$ to 1 per cent. solution of "bacillol" in water whereby all micro-organisms are destroyed. "Bacillol" is also applicable for sterilising the malt room, which is best effected by allowing the concentrated solution to evaporate in shallow pans.—E. F. A.

Diastatic saccharification; New researches on ——. L. Maquenne and E. Roux. Comptes. rend., 1906, 142, 1059—1065.

STARCH pastes of different origins were saccharified by malt at a temperature of 50° C., and the proportions of maltose produced were determined at intervals during four days, the results being calculated per cent. of the original weight of dry starch taken. The conditions of alkalinity of the media were varied in a definite manner, being either "normal," *i.e.*, the natural alkalinity of the starch and malt extract, "optimum" *i.e.*, with the addition of acid to the extent indicated in this J., 1906, 192, or "neutral" to methyl orange. The "optimum" condition of alkalinity, recognised in the dextrinification of the starch paste, is also found to be the most favourable for the production of maltose. Saccharification does not really stop at any intermediate stage, but proceeds to the end if sufficient time be allowed. The reaction can, however, be divided into two very distinct phases, the first of which takes place with extreme rapidity, and corresponds to the conversion of 70—85 per cent. of the starch into maltose, whilst the second phase, in which the remaining 15 per cent. of the original starch is saccharified, proceeds very slowly, and may extend over several days. This is regarded as evidence of the existence in crude starch of two constituents unequally sensitive to the action of amylase, one of the components, *i.e.*, pure amylose, being very readily saccharified, whilst the other, *i.e.*, amylopectin, is saccharified with great difficulty, but is nevertheless a true maltosane, distinguished from amylose by its insolubility in alkalis. The addition of small quantities of acid to malt extract lowers the power of resistance of the amylase to heat (temperature 58° C.) to an extent corresponding with the degree of neutralisation of the natural alkaline reaction by the acid. Hence the falling off of the saccharification when the medium is fully neutralised by acid is due to the rapid destruction of the amylase. The influence of the addition of acid to a malt extract, intensifying at first, and subsequently destructive, suggests to the authors that the amylase exists in the form of an unstable salt or compound with the basic mineral or nitrogenous constituents, *i.e.*, as a partially dissociated zymogen, more stable than the free amylase itself. The acid function recognised in starch is probably sufficiently pronounced to liberate the amylase from the zymogen. The extreme instability of free amylase would account for the fact that a slight alkalinity, equal to about two-thirds of the natural alkalinity, must be retained if the maximum intensity of saccharification is desired. Owing probably to the amphoteric nature of the amino-acids produced by the proteolytic enzyme, the reaction of the medium tends to re-adjust itself by a species of auto-regulation during saccharification. If the initial alkalinity is very high, as in the case of rice starch pastes, the alkalinity decreases in the course of saccharification; on the other hand, if the

initial alkalinity be reduced to the "optimum," or neutralised altogether by the addition of acid, it will be found to have increased at the end of the saccharification.
—J. F. B.



Mycoderma; Influence of —— on the reproductive and fermentative properties of yeast. I. A Kossowicz. Woch. f. Brau., 1906, **23**, 262—263.

In experiments made with a view of testing the existence of Wildier's "bios," the author made the observation that infection by mould fungi favoured the development of very minute quantities of yeast cells in mineral nutrient media under conditions in which similar or even larger quantities of pure yeast failed to develop. Mycodermæ also have a similar effect. Moulds and mycodermæ, even when they have no fermentative power, are capable of assimilating ammonium salts, and they excrete large quantities of invertase; they thereby assist the yeast in artificial media composed of cane sugar and saline nutrients. Mixtures of yeast and mycoderma can produce fermentation more readily than either in the pure state. It was found that a small quantity of yeast, which in the pure state showed a very small reproductive development, and produced no visible fermentation, multiplied a thousand times more strongly when mixed with a few cells of mycoderma, and set up a vigorous fermentation under the same conditions.

Lindner remarks, in connection with the above observation, that in the pressed yeast ("Lufthefe") industry, the practical man knows that the highest yield of yeast is obtained when there is a slight infection by mycoderma. It has always been assumed that such yeast is of inferior quality, but possibly this is not really the case. Perhaps the two organisms work together more vigorously than otherwise, owing to the fact that the mycoderma is able to assimilate the more or less poisonous metabolic excretion products of the yeast.—J F. B.

Mycoderma yeast; New variety of —— as a cause of saké disease. T. Takahashi. Bull. Coll. Agric., Tokyo, 1906, **7**, 101—104.

The author has recently examined a "turned" saké,

which proved to be infected with a new mycoderma yeast, which the author has named *Mycoderma saprogenes saké*. The saké contained 8·1 per cent. of alcohol by vol., 0·36 per cent. of free acid, and 1·5 per cent. of extractive matters. Pasteurised saké containing 17 per cent. of alcohol by volume was attacked when inoculated with this mycoderma yeast; after 10 days at 20°—28° C., the amount of alcohol was reduced to 9·37 per cent. *Mycoderma saprogenes saké*, as obtained by Lindner's droplet method, forms elliptical filamental or sausage-shaped cells, rarely globular (see figure). Two or three fat globules are frequently seen in the large cells. The yeast assimilates dextrose, levulose, sucrose, maltose, and galactose; ferments dextrose and galactose very feebly, but not levulose, sucrose, and maltose; and does not assimilate nitrates or nitrites. It rapidly oxidises alcohol to carbon dioxide and water, with formation of only a trace of organic acids. The growth of the yeast on koji-extract-agar, koji-extract-gelatin, wort-agar, bouillon-agar, wort-gelatin, and saké-agar is described. The yeast develops best at 25° C. It is distinguished from other varieties of mycoderma by its inability to ferment levulose, sucrose, and maltose, and also by the growth of stab-cultures on saké-agar. Also it differs from *Mycoderma cerevisiæ vini.* in that it develops readily on Mayer and Nägeli's solution containing 9 per cent. of alcohol, whilst Hayduck's solution containing 2 per cent. or 4 per cent. of acetic acid is unfavourable for its growth. The yeast is destroyed by exposure to a temperature of 70° C., or on exposure to 55° C., for five minutes. Its resistance to alcohol is considerably diminished by long artificial culture.—A. S.

Emulsin; Secretion of —— by yeast. L. Guignard. Bull. des Scien. pharmacol., 1906, **13**, 75; Woch. f. Brau., 1906, **23**, 252.

The fresh juice of elderberries contains no emulsin, and is entirely without action on amygdalin. But after the juice has started fermenting, the presence of hydrocyanic acid can be detected after 48 hours, and the reaction increases in intensity with the time. The author has isolated from the fermenting juice a species of yeast which appears to be *S. Pastorianus*, and which, like bakers' yeast, possesses the property of splitting up amygdalin. The yeast cells, therefore, secrete emulsin or a similar enzyme during the process of fermentation.—J. F. B.

Sarcina [in brewery yeast]. N. H. Claussen. Z. ges. Brauw., 1906, **29**, 339—342.

The sarcina of Bettges and Heller (this J., 1906, 227) agrees in properties with the author's *Pediococcus damnosus* (this J., 1904, 332). Like the latter, the above sarcina is also resistant to the action of acid ammonium fluoride, as is shown by the experiments of Bettges and Heller, although these authors arrive at the opposite conclusion. In some cases pediococcus forms apparently die when cultivated on gelatin plates, but this is due to lack of space preventing the organisms from developing. That these micro-organisms require room for their development is shown by the fact that the largest colonies always form in the body of the gelatin, where the concentration of cells is least.—T. H. P.

Milk and beer: The ropy fermentation of ——. F. C. Harisson. Rev. gen. du lait, 1906, **5**, 145; Woch. f. Brau., 1906, **23**, 252.

The author has studied a number of species of bacteria from ropy milk, and a species, *B. lactis aërogenes*, from ropy beer. These bacteria were isolated from a dairy in which ropy fermentation had become established. The author divides the bacteria into four classes: those previously studied by other authors and those isolated for the first time by himself, all from ropy milk; those belonging to the group of *B. lactis aerogenes*, and lastly, two coccus forms which were isolated from milk, and from the gullet of a dog. The nature of the ropy substance developed in the milk is not perfectly understood, but it is intimately connected with the body-substance of the organisms themselves, which possess a more or less strongly developed capsule. This substance is precipitated by acetic or hydrochloric acid. Alkalis dissolve the ropy masses; the ropiness of the liquid is not diminished by heating for 20 minutes at 100° C. The ropiness is developed just as much under aërobic conditions as in absence of air; oxygen has no influence on its formation. As a general rule the ropiness is proportional to the degree of development of the bacteria, so long as the reaction of the medium does not become acid.—J. F. B.

Champagne wines; Biological studies on ——. F. A. Cordier. Bull. des Scien. Pharmacol., 1906, **13**, 77; Woch. f. Brau., 1906, **23**, 252.

The wines of the Champagne and northern districts of France are generally fermented by only a single species of yeast, whilst those of the southern districts are always fermented by several species. In the Champagne wine there is a residue of lævulose remaining after the primary fermentation. This sugar is then fermented only with

great difficulty, and forms an obstacle to the rapid clarification of the wine; it also makes the wine particularly liable to ropy fermentation. In order to effect the rapid fermentation of the lævulose, the author has cultivated the typical yeast of the Champagne district for a prolonged period on solid artificial media containing no other sugar than levulose.—J. F. B.

Sachsia suaveolens: the wine-bouquet fungus. P. Lindner. Woch. f. Brau., 1906, **23**, 258—260.

Sachsia suaveolens was discovered by the author 18 years ago on the walls of the fermentation room of a distillery. It grows either in yeast-like forms or in mycelial threads with hyphæ like the mould fungi, and it produces a pleasant odour of fruity ethers. The fungus, when grown on wort-gelatin, gradually assimilates the whole of the culture medium, and forms a tough film of greenish colour. In presence of air a considerable accumulation of fat globules is observed. One of the most striking properties of this fungus is its very high attenuating power in beer wort. It is far stronger in this respect than the ordinary culture yeasts, and is equal to *Schizzosacch. Pombe* and *octosporus*. It ferments dextrin, dextrose, levulose, cane sugar, and maltose strongly, galactose, milk sugar, and β-methylglucoside moderately, and mannose and raffinose slightly. If air be excluded from a wort which has already been fermented by *Sachsia*, a further development of the fungus takes place, but the cells assume quite a different morphological form and manner of growth. The fungus produces an appreciable quantity of acid in the course of fermentation. In hopped wort of 14·3° Balling. it produced 6·9 per cent. of alcohol by volume, and the product had the flavour of porter. The most favourable temperature for its development lies between 20° and 25° C.; very little growth takes place above 30° C. In de-alcoholised beer the fungus produced a further quantity of 3·2 per cent. of alcohol by volume, Wibiral has invented a non-alcoholic drink by developing the fungus in apple juice or in a mixture of apple juice and wort soured by the lactic acid ferment. The growth is stopped as soon as the fungus film has been formed and alcoholic fermentation has commenced. The liquid is filtered, and saturated with carbon dioxide; the product somewhat resembles Moselle wine.—J. F. B.

Vinegar factory; Annual report of German experimental ——. F. Rothenbach. Woch. f. Brau., 1906, **23**, 260—261.

The report for 1906 deals with the introduction of pure cultures of bacteria in the experimental acetifiers. In the ordinary acetifiers the vinegar comes out with an acidity of 14·7—14·5 per cent. The vinegar from the acetifiers working with pure cultures is not so strong. *B. xylinum* can be detected in nearly all the acetifiers, although no visible formation of slime is observed either in the acetifiers or in the vinegar. The presence of enzymes in the acetifying bacteria could not be ascertained with certainty by the guaiacum and hydrogen peroxide test, since the bacteria yielded a blue coloration even after boiling. A wine-vinegar bacterium which yields on the large scale a vinegar of 8·0—8·5 per cent. strength has been isolated; this has even been acclimatised to an acidity of 11·2 per cent. Henneberg has obtained several species of bacteria from wine-vinegars which will acetify wine-vinegar worts up to 9 per cent. acidity, and are therefore useful in practice; they are being prepared and sold in the form of pure cultures. According to Henneberg, a temperature of 48°—50° C. maintained for a few minutes is sufficient to pasteurise "lager vinegar" effectively. The observation of Buchner and Meisenheimer that vinegar fermentation is due to the activity of enzymes secreted by the bacteria is confirmed. The tendency of some vinegars to frothing is attributed to a deficiency of carbon dioxide in their composition. Carbon dioxide is one of the fermentation products of the "quick" vinegar process. A vinegar of moderate acidity dissolves iron at the ordinary temperature; defective enamelled iron vessels are not suitable for the storage of vinegar.—J. F. B.

Beetroots; Industrial yield of alcohol from ——. D. Sidersky. Bull. Assoc. Chim. Suer. Dist., 1906, **23**, 1090—1092.

As the result of a prolonged period of very careful control of the weights and composition of the beetroots taken into work in the distillery, it was established that in the season 1905–6, 10,403 tons of beets were employed, and 6951 hectolitres of absolute alcohol, measured in the phlegms, were obtained: a yield of 66·81 litres per ton of beets. The beets were treated by diffusion, and the above weight represents cleaned beets ready for treatment; the loss of sugar in the diffusion amounted to 0·33 per cent. From the above data it is calculated that the yield amounted to 59·22 litres of absolute alcohol per 100 kilos. of sugar entering the factory, or 60·10 litres per 100 kilos. sent into the fermentation system. The author suggests that in beet-juice distilleries, the development of the yeast takes place without any appreciable expenditure of the saccharine constituents of the juice.
—J. F. B.

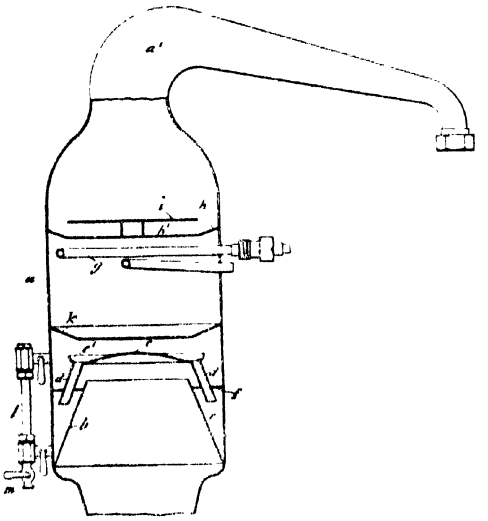
English Patents.

Kilns or oasts for drying hops, malt, and the like; Impts. in ——. The Electric and Ordnance Accessories Co., Ltd., Birmingham, R. Hancock, London, and R. F. Hall. Eng. Pat. 15,691, Aug. 1, 1905.

The air for drying the hops is passed through a tubular heater placed within the kiln, but at such a distance below the perforated drying floor that the materials are not directly influenced by the tubular heater. The latter is heated by steam from an external source of supply, and fans may be used to force the air through the heater.
—W. H. C.

Ethereal oils from blooms of hops; Extraction of ——. L. Nathan, Zurich, Switzerland. Eng Pat. 519, Jan. 8, 1906. Under Int. Conv., Jan. 19, 1905.

The essential oils of the hop blooms are extracted by a current of heated carbon dioxide, the gas being subsequently cooled to obtain the oils. The dried hops are added to the wort before boiling, and the oils extracted can be advantageously added after the boiling.—F. Shdn.



Beer, ale, and other liquids; Process and apparatus for fermenting ——. A. E. Edwards, London. From The Pfaudler Co., Rochester, N.Y., U.S.A. Eng. Pat. 18,658, Sept. 15, 1905.

The fermentation vessel consists of a closed iron tank, enamelled internally. The pitched wort is introduced into the tank up to a certain level, and is then stirred and aerated intermittently every three or four hours by the passage of a relatively strong current of air introduced near the bottom of the tank. The air is cooled, sterilised, and filtered by pumping it through a system of cooling pipes, then through towers containing gravel and a sterilising solution, *e.g.*, permanganate, and finally through cotton-wool. When fermentation has set in, a white foam forms on the top of the wort; the air current is then connected with a very fine distributing nozzle, and aeration of the wort is continued steadily for six to eight hours. As fermentation proceeds, after aeration is finished, the gas escaping from the pipe in the head of the tank gradually becomes richer in carbon dioxide, and when a test shows that this gas is approximately free from air, it is diverted by means of a 3-way cock into a pipe leading to the compressor. Fermentation is continued for five to six days, the maximum temperature being limited to 11° C. by means of an attemperator. When the gravity has fallen to 1 per cent. above the desired final gravity, holes in the upper part of the tank just above the level of the liquid are opened, and a current of sterilised air is admitted to the top of the tank by way of the gas-escape pipe. The whole of the carbon dioxide is thus expelled, and the last stages of fermentation are conducted in the presence of a gentle stream of pure air. After the beer is well "broken," its temperature is lowered to about 4° C., and it is drawn off through a racking device situated in the bottom of the tank into a chip-cask; the residue of yeast is then removed. The total duration of fermentation in the tank is seven to eight days.—J. F. B.

Fusel oils; Manufacture of ——. E. A. Mislin, Prague, and L. Lewin, Vienna. Eng. Pat. 10,435, May 18, 1905.

See Fr. Pat. 354,807 of 1905; this J., 1905, 1121.—T. F. B.

Distilling apparatus [Alcohol, &c.]; Impts. in ——. J. H. Covell, Montague, Cape Colony. Eng. Pat. 15,371, July 26, 1905.

The still head, *a*, has a horizontal cooling coil, *g*, for the purpose of causing the condensation of the higher boiling portions of the vapour coming from the still. Baffle plates, *i*, *h*, the latter being perforated as shown at, h^1, are arranged above the coil to assist in the condensation, and the condensed liquid is directed by the cone, *k*, on to the drip-plate, *c*, c^1, from which it flows by the pipes, *d*, into the chamber, *e*, formed by the cone, *b*, and the plate, *f*. The heavier liquids collect in, *e*, and when the gauge glass, *l*, shows that sufficient liquid has accumulated, it is drawn off through the tap, *m*. The uncondensed vapours pass on by the "swan neck," a^1, to the condenser.—W. H. C.

Evaporator for evaporating the liquid in brewers' wash, spent wash or pot ale from distilleries, sewage, waste or spent dyes, and the like, the evaporator being also applicable as a smoke washer. A. B. Lennox and P. Dawson. Eng. Pat. 9572, May 6, 1905. XVIII*B*., page 605.

Distillery refuse known as "pot ale" or spent wash; Treatment of ——, *for the production of fuel.* J. T. Connell, F. F. Haldane, and J. Thomson, all of Edinburgh. Eng. Pat. 13,914, July 6, 1905.

The spent wash, after being evaporated to a syrupy or viscuous condition, is forced by suitable means into a boiler furnace already containing a bright hot coal fire. The syrup may also be mixed with powdered coal, cinders, peat, or the like, and pressed into cakes or briquettes for use as fuel in ordinary grates.—W. P. S.

United States Patent.

Distillery "slop"; Desiccated ——, *and process of making same.* G. F. Ahlers. U.S. Pat. 821,326, May 22, 1906. XVIII*A*., next column.

German Patent.

Wood spirit; Continuous process for the preparation of pure, concentrated ——. J. Farkas. Ger. Pat. 166,360, Aug. 11, 1904.

Crude wood spirit is distilled, and the vapours are first passed through lime water, then through a warm, concentrated alkali solution (15°—20° B.), afterwards washed with stearic or other fatty acid, and finally with alkali to remove any entrained fatty acid. This treatment has the effect of removing all the aldehydic resins, higher alcohols, ketones, &c., which formerly had to be eliminated in a separate process.—T. F. B.

English Patents.

Liquids [Milk, &c.]; Method of treating ——, *by means of hydrogen peroxide.* F. Z. Franzén, Stockholm. Eng. Pat. 9703, May 8, 1905. Under Int. Conv., June 23, 1904.

See Fr. Pat. 355,457 of 1905; this J., 1905, 1184.—W.P.S.

Flour; Method of and apparatus for treating —— *with gases.* M. A. and C. P. Eybert, Livron, France. Eng. Pat. 26,777, Dec. 22, 1905. Under Int. Conv., July 18, 1905.

See Addition of July 18, 1905, to Fr. Pat. 353,179 of 1905; this J., 1905, 1319.—T. F. B.

United States Patent.

Distillery "slop"; Desiccated ——, *and process of making same.* G. F. Ahlers, Covington, Ky. U.S. Pat. 821,326, May 22, 1906.

A dry fodder is prepared from distillery slop by separating the latter into solid and liquid portions. The solid portions are dried to a granular and absorbent condition, whilst the liquid portions are concentrated to a syrup, which is then incorporated with the absorbent granular portion, and the whole is dried. The product may be mixed with starchy materials to form a properly balanced foodstuff.—J. F. B.

(*B*.)—SANITATION; WATER PURIFICATION.

Water gas and other gases in factories; Memorandum as to the use of ——. Home Office Memorandum (Form 827), May, 1906. [T.R.]

This memorandum contains a short summary of the accidents which have occurred through carbon monoxide poisoning during the last seven years, with a list of the causes to which they were traced. An account of the symptoms of this poisoning, and preventive measures to be adopted are given, and a notice, intended to serve as a model of one to be posted up near the place where danger exists, is appended.

English Patents.

Evaporator for evaporating the liquid in brewers' wash, spent wash or pot ale from distilleries, sewage, waste or spent dyes, and the like, the evaporator being also applicable as a smoke washer. A. B. Lennox, Newcastle-on-Tyne, and P. Dawson, Glasgow. Eng. Pat. 9572, May 6, 1905.

The evaporator, which may consist of several compartments of increasing area, is fitted either within the furnace flue or other source of heat, or connected with the flue, or within a casing fitted over and adapted to constitute part of the flue between the furnace or other source of heat and the chimney or outlet. The evaporator consists of a series of open-ended iron pipes or square casings fixed approximately smoke-tight into suitable orifices in a plate or plates adapted to cover the orifice from the flue, so that the hot gases travelling towards the chimney, pass through the pipes or casings. The liquid to be evaporated is sprayed into the interior of the outer casing, above the upper end of the evaporator, and passes down through the tubes, the remaining liquid being collected, and re-delivered through the sprays. Means for cleaning the evaporator tubes are provided, and a fan may be employed when the natural draught is not sufficiently strong. When the apparatus is used as a smoke washer, the smoke from the furnace is subjected to the scrubbing action of pure liquid.—T. H. P.

Ammoniacal liquor obtained by washing illuminating and heating gases; Treatment of certain products of ——. J. Radcliffe. Eng. Pat. 10,075, May 13, 1905. III., page 584.

French Patent.

Water and other liquids; Apparatus for the purification of ——. P. G. Griffith. Fr. Pat. 360,970, Dec. 27, 1905. Under Int. Conv., Dec. 31, 1904.

The invention relates to an apparatus by means of which water or other liquid is heated to a temperature of from 65° to 85° C. for a period of not more than 25 seconds, and then rapidly cooled, in order to destroy any pathogenic organisms present. The water to be treated is received in a tank, provided with a ball-tap, and from this flows down a pipe to a space at the bottom of a cylindrical vessel fitted with a large number of tubes. The number of the latter is such that the space between the tubes and the walls of the cylinder is about equal to the capacity of the tubes. The tubes project through the top and bottom covers of the cylinder so that the water delivered by the above mentioned pipe passes upwards through them, and is then led into the lower part of a heating apparatus. This consists of four concentric cylinders connected with one another, the innermost one being heated by a flame placed under it. A small chamber placed at the top of the innermost heating cylinder is provided with a valve, regulated by a capsule containing a liquid of constant boiling point, which allows the water to escape only when heated to the desired temperature. The heated water is then conducted to the space in the tubular apparatus outside the tubes, where it is cooled by the water flowing through the tubes. Corrugated metallic sheets may be placed in this space to accelerate the cooling. A second valve is provided at the top of the heating chamber to allow of the escape of air. The water leaves the cooling cylinder through a pipe at the bottom, which pipe extends upwards so as to keep the cylinder full of water. (See also Eng. Pat. 17,984 of 1904; this J., 1905, 811.)—W. P. S.

(C.)—DISINFECTANTS.

Phenol [as a disinfectant]; Efficacy of ——, *compared with other poisons.* Th. Bokorny. Chem.-Zeit., 1906, **30**, 554—556.

The author has compared quantitatively the effects of certain organic poisons on simple organisms such as yeast. The first four items in the following table are his results, the others being collected for comparison:—

	Weight in grms. required to kill 10 grms. of yeast.
Phenol	0·05 —0·1
Formaldehyde	0·02 —0·04
o-Hydroxybenzaldehyde	0·25 —0·5
Acetic acid	0·2 —0·4
Copper sulphate	0·001—0·0025
Mercuric chloride	0·005—0·01
Silver nitrate	0·01 —0·02
Lead acetate	0·05 —0·1
Caustic soda	0·05 —0·1
Potassium permanganate	0·02 —0·05
Chlorine	0·015—0·03
Tannic acid	0·5 —1·0

Substances, such as acetaldehyde, which act as a poison to moulds when present in sufficient quantity, may in more dilute solutions act as a food, assisting their growth.—F. Sodn.

Disinfectants from naphthols. H. Schneider. Z. Hyg., 1906, **52**, 534—538. Chem. Centr., 1906, **1**, 1680.

The naphthols can be dissolved in alkali carbonate solutions, and the author states that such solutions contain the naphthol in the free state, not combined with the alkali, and have a considerably greater disinfecting power than solutions of alkali naphtholates. Dry mixtures of naphthol and anhydrous sodium carbonate can be kept for any length of time without undergoing alteration. The most effective mixture is one containing equimolecular proportions of naphthol and carbonate; with such a mixture, a 1 per cent. solution of the naphthol is the strongest obtainable. By increasing the proportion of sodium carbonate, more naphthol can be dissolved, but the disinfecting power of the dissolved naphthol is reduced. The solutions exert a disinfecting action on vegetative forms of anthrax, more than twice as great as that of "Lysol." Staphylococci and typhus bacilli are destroyed in a very short time by 0·5 and 1 per cent. solutions of β-naphthol and alkali carbonate. α-Naphthol has a similar action, but is not so useful in practice as β-naphthol, owing to its dearer price and its inferior keeping qualities.—A. S.

English Patents.

Gaseous mixture [Sulphur dioxide, &c.] for extinguishing fire, killing insects, &c.; Apparatus for the production and distribution of a ——. R. Marot, Paris. Eng. Pat. 9536, May 5, 1905.

The claims relate to improvements in the apparatus described in Eng. Pat. 14,372 of 1904 (this J., 1904, 879). The improvements consist mainly in arrangements for the rapid production of a large quantity of sulphur dioxide, liquid sulphurous acid being employed. The vaporised acid is mixed with a regulated supply of air, the cold produced by the vaporisation of the acid being used to cool the water-jacket of the motor. The mixture of gases then receives the addition of a further quantity of heated sulphur dioxide before being led into the chamber where it is subjected to the electric discharge (see original specification). A fan is provided to draw the mixture from the electric chamber, and to discharge it wherever required. When the motor is only used for re-aspirating the mixture of gases from the place where it is required, an arrangement is provided, by means of which the water-jacket of the motor is separately cooled. Besides being heated by the combustion gases of the motor, the heating chamber is also supplied with a source of heat from a series of Bunsen burners.—W. P. S.

Vegetation; Materials for the destruction or retarding of ——. [*Weed-killer.*] A. Blackie, Tunbridge Wells. Eng. Pat. 10,450, May 18, 1905.

The claims of this patent are for the use of solutions of boric acid and soluble borates, or mixtures of the same as weed-killers. Other substances may be added to the solutions.—W. P. S.

XIX.—PAPER, PASTEBOARD, Etc.

(*Continued from page 556.*)

Cellulose acetates; Studies on ——. H. Ost. Z. angew. Chem., 1906, 19, 993—1000.

THE three processes for preparing soluble acetates of cellulose which have been investigated by the author, *viz.*, Cross and Bevan's process by the action of zinc acetate and acetyl chloride, Lederer's process by the action of acetic anhydride and sulphuric acid on hydrocellulose, and Bayer's process by the action of the same reagents on normal cellulose, all yield the same product, triacetylcellulose $C_6H_7O_5(C_2H_3O)_3$. At the same time, the author is inclined to doubt whether a triacetate of normal cellulose really exists, and to regard these products as the triacetates of a series of hydrocelluloses of varying degrees of degradation, the position of any member in the series being determined by the relative viscosity of its solution, and the elasticity of its films. The author estimates that the relation of such a hydrocellulose to the normal cellulose may be expressed by the fixation by hydrolysis of 1 mol. of water on to 6 mols. of cellulose. The incipient hydrolysis of the cellulose which appears to be a condition necessary for the esterification, may be effected either simultaneously, as in Bayer's process, or in a separate preliminary operation, as in Lederer's process. The author contends that the cellulose acetate obtained by Cross and Bevan's process is not a tetracetate as asserted by the discoverers, but a triacetate identical with the other products. The error which is thus stated to exist in the latter authors' work is attributed to the fact that the saponification of these esters by boiling aqueous-alcoholic potash is accompanied by the production of acids at the expense of the cellulose residue, and that the results of saponification are too high. The author prefers to effect the hydrolysis by means of equal volumes of sulphuric acid and water, acting in the cold for about 48 hours, and to distil off the acetic acid in a current of steam for 4—5 hours. The production of all these triacetates is preceded by the production of diacetates, which can be isolated by stopping the reaction whilst still incomplete. The analogy between the acetate and nitrates of cellulose is complete; in both cases the highest limit of esterification corresponds with the substitution of three hydroxyl groups in each C_6 unit, the products not being esters of normal cellulose but of modified, hydrolysed, or oxidised derivatives of cellulose.
—J. F. B.

ENGLISH PATENT.

FRENCH PATENTS.

Cellulose preparations; Apparatus for boiling impure liquids, especially those which, during the heating, deposit sediment or solid matter of any kind, and in particular ——. H. Kestner. Fr. Pat. 361,248, Dec. 4, 1905.

THE liquid to be evaporated is heated in a number of tubes set at a slight angle to the vertical. The upper ends of these tubes open out into a wide vessel, and the lower ends communicate by means of a wide bent pipe with a horizontal cylindrical vessel, which is joined by another wide vertical pipe to the upper vessel. The liquid rises through the heating tubes, carrying with it the solids separating out, which are buoyed up by bubbles of steam. On emerging into the upper vessel, these bubbles break, and the liquid *plus* suspended matter falls through the wide vertical pipe into the lower cylinder, where the suspended matter collects, the liquid again circulating upwards through the heating tubes, and being further concentrated.—A. G. L.

(*Continued from page 560.*)

Aconitine and aconine from Aconitum napellus. H. Schulze. Arch. Pharm., 1906, 244, 136—159.

THE author gives a complete historical survey of previous investigations of aconitine and aconine. The author used aconitine obtained from *Aconitum napellus*, and after crystallising from methyl alcohol the m.pt. was 197°—198° C. Analyses of the base and its derivatives point to the formula $C_{34}H_{47}NO_{11}$, or $C_{34}H_{45}NO_{11}$. The base was hydrolysed by heating under 6—7 atmospheres pressure in an autoclave, when there was an 85 per cent. yield of aconine. Aconine hydrochloride, $C_{25}H_{39}NO_9,HCl,2H_2O$, or $C_{25}H_{41}NO_9,HCl,2H_2O$, melted at 175°—176° C. The hydrobromide, $B,HBr,1\frac{1}{2}H_2O$ (taking B, as alkaloid base) melted at 225° C. Aconine contains one N-methyl group and four methoxyl groups. Although a tertiary base, it does not react with methyl iodide or methyl sulphate. The free hydroxyl groups are alcoholic in character, not phenolic. By treating aconine with acetyl chloride, tetra-acetylaconine, $C_{33}H_{43}NO_{13}$, or $C_{33}H_{47}NO_9$, m.pt. 231°—232° C., is obtained. The author finds that tetra-acetylpikraconitine (=triacetylaconitine) m.pt. 207°—208° C., gives an amorphous gold salt of normal constitution. If aconitine be heated with methyl alcohol in a sealed tube to 120°—130° C., a methoxyl group takes the place of the acetyl group. The hydrobromide of the new base, $C_{32}H_{47}NO_{10},HBr,3H_2O$, melts at 188°—189° C. The hydrochloride, $B,HCl,3H_2O$, melts at 190° C. On heating this base with water for 24 hours to 150°—160° C., it decomposes into benzoic acid, methyl alcohol, and aconine. The author considers that the acetyl and benzoyl groups in aconitine are in neighbouring positions. Aconitine is stable to permanganate in acid solution. By oxidation with chromic acid a small quantity of a base was obtained, together with a larger proportion of a substance possessing acid and basic properties. The hydrochloride of the base, $C_{24}H_{37}NO_8,HCl,3H_2O$, or $C_{24}H_{35}NO_8,HCl,3H_2O$, melted at 213° C. It is oxidised by permanganate in acid solution.—F. SHDN.

Aconitine and aconine from Aconitum napellus. H. Schulze. Arch. Pharm., 1906, 244, 165—196.

IN this paper the author gives the experimental details of the results recorded in a previous paper (see previous abstract). The analytical figures and the melting point of the aconitine obtained by the author from the roots of *Aconitum napellus* agree with those obtained by Freund and Beck (this J., 1904, 1042). A crystallographic examination of aconitine was made. From his results the author concludes that the aconitine obtained by Dunstan from English aconite root is identical with the German crystalline aconitine. This is opposed to the view recently expressed by Dunstan (this J., 1905, 1252).—F. SHDN.

Ephedrine; Conversion of —— *into pseudo-ephedrine.* E. Schmidt. Arch. Pharm., 1906, 244, 239—240.

EPHEDRINE can be converted into pseudo-ephedrine by heating with 25 per cent. hydrochloric acid on the water-bath for 12 hours. The transformation is not complete, but good yields of pseudo-ephedrine are obtainable. The pseudo-ephedrine thus produced, is chemically, optically, and crystallographically identical with the natural base. Whilst ephedrine is lævo-rotatory, pseudo-ephedrine is more strongly dextro-rotatory. Both substances on exhaustive methylation yield an unsaturated alcohol, C_9H_9OH, but the alcohols differ in their boiling points.
—F. SHDN.

Musk; *Presence of an odorous ketone, muskone in* ——. Schimmel's Report, May, 1906, 94—96.

500 GRMS. of musk, when submitted to prolonged distillation with steam, gave 1·4 per cent. of strong smelling brown oil on shaking out the aqueous distillates with ether, and evaporating the solvent. The chief constituent of this oil is a ketone. This was isolated by saponifying the oil, washing with water, in order to remove fatty acids and fats, and then subjecting it to fractional distillation under 2 mm. pressure, when the ketone distilled at 142°—143° C. It forms a viscous colourless oil with an intense and pure musk odour. Under 752 mm. pressure it boils at 327°—330° C.; sp. gr. at 15° C. 0·9268; $a_D = -10° 6'$; $n_D^{25°} = 1.47900$; soluble in alcohol in all proportions. It gives analytical figures agreeing with the formula $C_{15}H_{28}O$ or $C_{16}H_{30}O$. It forms crystalline compounds with hydroxylamine and with semicarbazide; the semicarbazone, purified by recrystallisation from alcohol, has the m. pt. 133°—134° C. The fine white prisms of the semicarbazone are absolutely odourless, but develop the powerful odour of muskone when a trace is heated with dilute sulphuric acid. Muskone is considered to be the sole odorous principle of value in musk, other odorous bodies present being unpleasant.—J. O. B.

Oils of Galician fennel and Laurus mobilis leaves; *Essential* ——. Schimmel's Report, May, 1906, 36—39; 43.

IN addition to the previously recorded constituents of fennel oil, camphene and α-phellandrene have been detected, together with traces of basic constituents in the first portion of the distillate. A small quantity of aldehydes was also found. Cymene, stated by Tardy to occur, was not present in the oil examined.

Linalôol and eugenol methyl ether are added to the number of the constituents of oil of sweet bay leaves.

—J. O. B.

Aluminium phenolate. A. N. Cook. J. Amer. Chem. Soc., 1906, **28**, 608—617.

THE best method of preparing aluminium phenolate is to heat from 100 to 500 grms. of phenol in a flask attached to a reflux condenser, and to add the aluminium gradually in the form of strips. An analysis showed that the phenolate contains 9·3 per cent. of aluminium, a quantity somewhat larger than that calculated for the formula $Al(OC_6H_5)_3$, and probably due to the high temperature resolving some of the aluminium phenolate into aluminium oxide and phenyl ether. Aluminium phenolate is a translucent, brittle solid, which keeps fairly well in closed vessels. It melts at 265° C., has a sp. gr. of 1·23, and is soluble in chloroform, carbon bisulphide, aniline, carbon tetrachloride, and acetone and in methyl, ethyl, and amyl alcohols, if these be entirely free from water. It is also soluble in hot benzene, toluene, and xylene. Water decomposes aluminium phenolate with the evolution of heat, various hydrates being formed according to the temperature of the solution; bromine decomposes it, tribromophenol and tribromophenol bromide being formed. When treated with nitric acid, aluminium phenolate yields orthonitrophenol, 1.2.4-dinitrophenol, and picric acid, the quantities of each produced depending on the concentration, the temperature, and the time employed in the reaction. Aluminium phenolate dissolves in anhydrous alcohol without evolution of heat. On adding a little water, a bulky precipitate of aluminium alcoholate, $Al(OC_2H_5)_3$, is thrown down, the alcohol radical simply taking the place of the phenyl. A similar reaction takes place in the case of ether. Hydrochloric, sulphuric, and hydrofluoric acids decompose the compound, phenol being liberated and the corresponding aluminium salts formed. Acetic acid attacks it but slowly, and the weaker organic acids have no action on it. By distilling aluminium phenolate, a small quantity of benzene, phenol, a varying amount of phenyl ether, and some higher boiling substances are obtained. (See also Gladstone and Tribe, Chem. Soc. Trans., 1881, 9.)—W. P. S.

Mercury oxycyanide. K. Holdermann. Arch. Pharm., 1906, **244**, 133—136.

THE author considers that the formula CN.Hg.O.Hg.CN well represents the constitution of solid mercury oxycyanide. In solution, a molecule of water is taken up, and a hydroxycyanide, Hg(OH)CN is formed, which dissociates into hydroxyl-ion and the complex ion, $HgCN$. Mercury oxycyanide can be readily prepared by a method suggested by Prussia (Gazz. chim. ital., 1898, **28**, II., 116). 125 grms. of mercuric acetate and 105 grms. of mercuric cyanide are dissolved in about a litre of boiling water. On adding N/1-caustic soda solution till the liquid is alkaline to phenolphthalein, a crystalline precipitate of mercury oxycyanide is formed.—F. SHDN.

Bismuth chloride; *New organic double salts of* —— L. Vanino and F. Hartl. Arch. Pharm. 1906, **244**, 216—220.

BISMUTH chloride is dissolved in alcohol, acetone, or ether, and the solution made clear by the addition of a little hydrochloric acid. This solution is heated, and a hot concentrated solution containing a molecular proportion of a base is then added. The double salts are immediately precipitated. *Diphenylamine bismuth chloride*, $(C_6H_5)_2NH$, $BiCl_3$, forms well-defined monoclinic crystals. *p-Nitrosodiphenylamine bismuth chloride*, $(C_6H_5)_2N.NO$, $BiCl_3$, comes down as dark crystals. *2-Nitrosodimethylaniline-3-bismuth chloride*, $2C_6H_4.NO.N(CH_3)_2$, $3BiCl_3$, is a microcrystalline powder. *Aldehyde ammonia bismuth chloride*, $(CH_3.CH.NH)_3$, $3BiCl_3$, is obtained as a yellowish-brown precipitate. *Methylamine hydrochloride bismuth chloride*, $3CH_3NH_2HCl$, $2BiCl_3$, forms long hexagonal needles. *Rheumatine bismuth chloride*, $C_{34}H_{44}N_2O_7$, $2BiCl_3$, forms small matted needles. *Quinaphenine bismuth chloride*, $2C_6H_5NH.CO.O.C_{20}H_{23}N_2O$, $5BiCl_3$, is obtained as a yellow precipitate. *Piperazine bismuth chloride*, $2C_4H_{10}N_2$, $3BiCl_3$, forms small quadratic crystals.

—F. SHDN.

Phosphorus; *Bologna* ——. L. Vanino. J. pr. Chem., 1906, **73**, 446—448.

PHOSPHORESCENT calcium sulphide or zinc sulphide, laid on black paper which covers a photographic plate, affects the plate; but if it be contained in a celluloid case it is without action. Since a radio-active lead preparation affects the plate almost equally whether laid directly on the black paper or contained in the celluloid case, it appears that celluloid is transparent to the β- or γ-radiation, and the action of the phosphorescent sulphide is not due to the emission of these rays, but possibly to minute quantities of hydrogen sulphide, which penetrate the black paper.

The author finds that in preparing phosphorescent calcium sulphide, the presence of calcium fluoride in the mixture enables a good phosphorescent preparation to be obtained at a much lower temperature than without it. He also finds that a mixture which on heating only produces a small proportion of the sulphide, or a mixture of the sulphide with a considerable proportion of inert substance, may show a very strong phosphorescence.

ENGLISH PATENTS.

Aminobenzoic acid alkamine esters and derivatives thereof; *Manufacture of* ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Hoechst-am-Main, Germany. Eng. Pat. 17,162, Aug. 24, 1905.

THE new aminobenzoic acid alkamine esters are stated to be valuable local anæsthetics. The esters are produced by reducing nitrobenzoic acid alkamine esters, by reducing azo and azoxybenzoic acid alkamine esters, by heating amino-

benzoic acid esters with alkamines, by treating aminobenzoic acids with alkamines according to the well-known methods for the manufacture of esters, or by heating aminobenzoic acid esters of halogen substituted alcohols with ammonia, or primary and secondary amines.
—F. Shdn.

Polychloranilines; New derivatives of certain ——. [*Substitutes for camphor in manufacture of celluloid*]. J. Y. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 8077, April 3, 1906.

This invention relates to the manufacture of a new class of alkyl-acyl derivatives of polychloranilines containing three or more atoms of chlorine, two of which are in the ortho positions to the amino group. These new derivatives can be obtained by the action of an acid chloride or acid anhydride on the corresponding alkyl derivatives. Or, the alkali salts of the acyl compounds can be treated with a halogen alkyl compound. The new compounds of this class can be used as substitutes for camphor in the production of substances like celluloid. The methods of preparation of the following derivatives are described in this patent; *s*-methyl-acetyl-trichloranilide, m.pt. 89°—90° C.; *s*-mono-ethyl-acetyl-trichloranilide, m.pt. 50°—51° C.; *s*-ethyl-benzoyl-trichloranilide, m.pt. 127°—128° C.; *as*-ethyl-acetyl-tetrachloranilide, $N(C_2H_5)(C_2H_3O):Cl:Cl:Cl:Cl = 1:2:3:4:6$, m.pt. 73°—74° C.; *as*-methyl-acetyl-tetrachloranilide, m.pt. 96°—97° C.; *s*-benzyl-acetyl-tetrachloranilide, m.pt. 97° C.; benzyl-benzoyl-tetrachloranilide, m.pt. 134° C.; *s*-benzyl-acetyl-trichloranilide, m.pt. 61° C.—F. Shdn.

Phosphoric acid; Manufacture of an officinal preparation of ——. J. Nicolaïdi, Paris. Eng. Pat. 15,118, July 22, 1905.

A preparation, stated to be solid and quite stable, and containing free phosphoric acid, is obtained by mixing phosphoric acid with milk sugar, adding sufficient gum arabic to give the mixture the necessary consistency, adding a further quantity of phosphoric acid, macerating the mixture for a few hours, granulating, and finally drying the product at 45°—50° C. The most suitable proportions are given as 100 c.c. of phosphoric acid, 37·5° B., for each kilo. of milk sugar.—T. F. B.

United States Patents.

Alkamine ester [*of alkylaminobenzoic acids*]. F. Stolz and B. Reuter, Assignors to Farbwerke vorm. Meister, Lucius und Brüning, Höchst on the Maine, Germany. U.S. Pat. 820,830, May 15, 1906.

Benzoylsuccinylperoxide and process of making same. A. C. Houghton, Syracuse, N.Y. U.S. Pat. 821,291, May 22, 1906.

Benzoylsuccinyl peroxide is a monobasic compound, obtained by the action of benzoic peracid on succinic anhydride; it is a colourless, crystalline substance, possessing an aromatic odour and powerful germicidal properties. It is soluble in alcohol, benzene and chloroform, and insoluble in petroleum spirit; its m.pt. is 96°C. It is slowly decomposed by water into benzoic peracid and succinic acid.—T. F. B.

Dialkylbarbituric acids; Process of making ——. W. Traube, Berlin. U.S. Pat. 822,165, May 29, 1906.

See Eng. Pat. 14,161 of 1905; this J., 1905, 1188.—T. F. B.

German Patents.

Anhydrides of monobasic organic acids; Process of preparing ——. Verein f. Chem. Industrie. Ger. Pat. 167,304, June 26, 1902. Addition to Ger. Pat. 161,882, March 30, 1902 (this J., 1905, 1323).

The mixture of alkali salt and alkaline earth salt is treated with a mixture of sulphur dioxide and chlorine, instead of with sulphuryl chloride. In presence of traces of moisture, a small quantity of organic acid is liberated, which acts as "contact material" for the formation of sulphuryl chloride; the apparatus is cooled externally during the process, and the anhydride finally isolated by distillation. (See also Ger. Pat. 163,103; this J., 1906, 392).—T. F. B.

Hæmoglobin preparation of the colour of arterial blood; Process for producing a stable, palatable ——. Kalle und Co., A.-G. Ger. Pat. 167,081, Oct. 16, 1903.

A current of sterilised air at the ordinary temperature is blown through an ethereal solution of hæmoglobin, obtained by extracting defibrinated blood with ether.
—T. F. B.

Aldehydes, alcohols, and [*fatty*] *acids; Process of producing* ——. Chem. Fabr. Flörsheim, Dr. H. Noerdlinger. Ger. Pat. 167,137, Jan. 16, 1904.

The liquid products obtained by passing air, oxygen, or ozonised air through oils or fats are treated by any known method for the isolation of the acids, alcohols, and aldehydes which they contain; the aldehydes and alcohols are said to include, amongst others, those of the C_6 series, hitherto only obtained with difficulty. The products are stated to be applicable to medicine, perfumery, &c.
—T. F. B.

Hydroxy-derivatives of the benzene series and their substitution products; Process for preparing ——. Soc. Chim. des Usines du Rhone, St. Gilliard, P. Monnet, et Cartier. Ger. Pat. 167,211, Jan. 30, 1904.

Hydroxy-compounds of the benzene series are easily obtained by heating an aqueous solution of the corresponding diazonium salt and copper sulphate; the diazonium compound may be slowly added to a boiling aqueous solution of copper sulphate, the temperature being maintained by direct heat, or by passing a current of steam through the solution.—T. F. B.

p-Dialkylaminobenzhydralamines; Process for preparing ——. E. Merck. Ger. Pat. 167,463, Feb. 20, 1904. Addition to Ger. Pat. 167,462, Jan. 9, 1904.

p-Dialkylaminobenzhydralamines are produced by the action of potassium phthalimide on the halogen acid esters of *p*-dialkylaminodiphenylcarbinols, the phthalic acid radical being subsequently eliminated, preferably in ammoniacal solution. The yield is stated to be considerably higher than when ammonia is used in place of phthalimide.
—T. F. B.

Copaïba balsam; Process for preparing neutral preparations from ——. Knoll und Co. Ger. Pat. 167,170, May 29, 1904.

Copaïba balsam, or the resinous saponifiable product from which the illurinic acid has been extracted, is converted into a neutral substance, insoluble in alkali, by esterification or by acidylation, *e.g.*, with acetic anhydride, benzoyl chloride, &c. The product is said to possess no irritant properties, and not to be decomposed in the digestive tract.—T. F. B.

Aminoguanidine; Process of preparing —— *from nitroguanidine.* C. F. Boehringer und Soehne. Ger. Pat. 167,637, Aug. 17, 1904.

Aminoguanidine may be obtained by the electrolytic reduction of nitroguanidine in a neutral suspension, using a tin cathode; other cathodes may be employed, provided that tin powder or a tin salt be present.—T.F.B.

Cyanamide and urea; Process for preparing acidyl derivatives of ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 167,138, Dec. 6, 1904.

By the action of cyano- or halogenated acetic esters on cyanamide, cyano-acetylcyanamide, $CN.CH_2.CO.NH.CN$, is produced; in the case of most monoalkylcyanamide derivatives, however, an acidylurea derivative is formed, *e.g.*, with methylcyanamide, the following reactions take place—

$$NC.CH_2COOH + NC.NH.CH_3 =$$
$$NC.CH_2.CO.N:C(OH)NH.CH_3 =$$
$$NC.CH_2.CO.NH.CO.NH.CH_3.$$

—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page 560.*)

ENGLISH PATENT.

Photographic pictures; Impts. in ——, in the process of making them, and in sensitive plates therefor. G. N. Pifer, Cleveland, U.S.A. Eng. Pat. 22,735, Nov. 6, 1905.

SEE U.S. Pats. 804,038 and 804,039 of 1905; this J., 1905, 1255.—T. F. B.

UNITED STATES PATENTS.

Photographs in natural colours; Process for the production of ——. J. Szczepanik, Vienna. U.S. Pat. 821,200, May 22, 1906.

SEE Eng. Pat. 10,812 of 1902; this J., 1902, 1097.—T. F. B.

Photographic sensitive emulsions; Base or support for ——. J. Findlay, Ilford. Assignor to Bromar, Ltd., London. U.S. Pat. 822,107, May 29, 1906.

SEE Eng. Pat. 5948 of 1904; this J., 1905, 512.—T. F. B.

FRENCH PATENTS.

Lighting compositions for photography in artificial light; Preparation of ——. Soc. Anon. des Plaques et Papiers Photographiques A. Lumière et ses fils. First Addition, dated March 21, 1905, to Fr. Pat. 360,588, March 2, 1905.

THE use of antimony chromate (1 part) mixed with magnesium powder (2 to 3 parts) is especially claimed in this addition. It is further specified that two or more of the chromates named in the principal patent (see this J., 1906, 560) may be added to magnesium, or to a mixture of magnesium and aluminium.—T. F. B.

Lighting compositions for photography in artificial light; Preparation of ——. Soc. Anon. des Plaques et Papiers Photographiques, A. Lumière et ses fils. Second Addition, dated March 22, 1905, to Fr. Pat. 360,588, March 2, 1905.

OXIDES of copper, iron, cobalt, &c., obtained by heating the nitrates or other neutral salts of acids possessing an oxidising action, may replace the chromates in the principal patent (this J., 1906, 560) to form lighting compositions which burn rapidly, giving flashes of great actinic power, but making slightly more noise and smoke than those prepared with chromates. The proportions used are one part of magnesium and one to two parts of the metal oxide.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

(*Continued from page 561.*)

Explosion of nitroglycerin in waste acid; Circumstances attending an ——, which occurred at the chemical works of Messrs. F. W. Berk and Co., Ltd., at Abbey Mills, Stratford-by-Bow, in the County of Essex, on Jan. 15, 1906. By Capt. J. H. Thompson, H.M. Chief Inspector of Explosives.

A QUANTITY of waste acid from the manufacture of nitroglycerin had been sent from the factory of the Explosive and Chemical Products Co. for denitration, and the plug of one of the drums was being loosened by hammering, when a violent explosion occurred, killing a workman. The cause of the explosion is traced to the presence of a film of nitroglycerin on the surface of the acid, separation having probably occurred during transit. The acid had not been allowed to stand in after-separators, but to prevent separation of the dissolved nitroglycerin, 2—3 per cent. of water had been added, a precaution which has been looked on by many as sufficient. Since the behaviour of waste acid under varying conditions of cold is not definitely known, experiments were carried out for H.M. Inspector at Waltham Abbey and Ardeer which indicate that even after long standing in after-separators a considerable quantity of nitroglycerin still remains in solution, which is apt to separate on lowering the temperature. The addition of water serves to keep the nitroglycerin in solution, but as much as 5 per cent. of water should be added to prevent separation on cooling. For safety, however, nitroglycerin waste acid should not be transported until it has first been denitrated by the action of heat.—B. J. S.

ENGLISH PATENTS.

Smokeless powders; Impts. in ——. A. T. Cocking and Kynoch, Ltd., Birmingham. Eng. Pat. 15,565, July 29, 1905.

CLAIM is made for the use of olive oil as an ingredient of propellants to lower the temperature of combustion together with vaseline, if necessary, to diminish the rate of burning. Thus, in the manufacture of cordite, the usual 5 per cent. of vaseline is replaced by a mixture of 3·75 per cent. of vaseline and 2·5 per cent. of olive oil. It is stated that the resulting powder possesses great stability.—B. J. S.

Smokeless powders; Impts. in ——. A. T. Cocking and Kynoch, Ltd., Birmingham. Eng. Pat. 15,566, July 29, 1905.

AN alkali carbonate or alkaline-earth carbonate is introduced into a propellant in order to neutralise the acid products of combustion, and lubricate the gun-barrel. In the case of potassium and sodium carbonates, excessive smoke is produced, whilst with barium, strontium, and calcium carbonates, the lubricating effect is not so good. By using a mixture so that the residue on explosion contains 2·8 per cent. of barium carbonate and 0·55 per cent. of potassium carbonate, it is possible to combine the useful properties of both carbonates. This is best accomplished by incorporating into the powder 4 per cent. of barium tartrate and 0·9 per cent. of potassium tartrate in a very fine state of division.—B. J. S.

Noxious or poisonous fumes, or gases, in blasting operations; Means for neutralising the —— in mines and the like. H. Walker, Knights, Transvaal. Eng. Pat. 24,002, Nov. 21, 1905.

TEN pounds of potassium permanganate, 1 drm. of potassium chlorate, if used in the form of fine crystals, or 2 drms if used in the form of powder, and ½ to 1 drm. of ammonium chloride, are intimately mixed, and made up into cartridges. These cartridges are placed in the blasting holes together with the dynamite, &c., one ½-lb. cartridge of the mixture being used for every five ½-lb. dynamite cartridges. The function of the potassium chlorate is to act as detonator to the permanganate in the mixture.—A. G. L.

UNITED STATES PATENT.

Blasting-powder. B. Eberle, Passaic, N.J. U.S. Pat. 820,854, May 15, 1906.

THIS invention relates to a blasting compound consisting of 4 lb. of saltpetre, 1½ lb. of potassium chlorate, 1½ lb. of sugar, 3 oz. of phosphorus, ½ lb. of sulphur, and ½ lb. of "manure."—B. N.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page 563.*)

APPARATUS, ETC.

Electrochemical analysis; A simple form of rotating electrode for ——. F. M. Perkin. Faraday Soc. Trans., June 12, 1906. [Advance proof.]

TWO concentric coils of platinum-iridium wire of 1 mm. thickness serve as electrodes, the central cathode being rotated. Nickel wire cathodes have also been used with some success.—R. S. H.

ENGLISH PATENT.

ts; Apparatus for use in analysing ——. E. Schatz, Frankfort on Maine, Germany. Eng. Pat. 25,466, Dec. 7, 1905. Under Int. Conv., Dec. 7, 1904.

E Fr. Pat. 359,352 of 1905; this J., 1906, 394.—T. F. B.

INORGANIC—QUALITATIVE.

ckel; Detection of ——. *New reaction.* C. Reichard. Chem.-Zeit., 1906, **30**, 556—557.

IE substance is mixed with dry methylamine hydrochloride or a few drops of its concentrated solution, and e mixture heated carefully in a small porcelain capsule til white fumes are evolved. A deep blue colour slowly velops which disappears on cooling, and appears again reheating as long as any methylamine remains. Cobalt der similar circumstances gives a dark-blue colour, t this does not disappear immediately on cooling, a haviour which is characteristic of nickel. The reaction is tremely delicate.—F. Sodn.

n; Detection of ——, *in woollen goods.* D. Paterson. J. Soc. Dyers and Col., 1906, **22**, 189—190.

E method consists in examining the strongly heated n of the woollen thread or fabric for any appearance of a aracteristic indigo-blue iridescence or metallic reflex. has been possible to detect by this test the presence tin in a small thread of olive-coloured carpet yarn ighing only 0·01 grm., and containing about 0·00015 n. of tin.—D. B.

INORGANIC—QUANTITATIVE.

ecipitates suspended in liquids; Pyknometric determination of weight and volume of ——. H. Gillot and A. Grosjean. Bull. Assoc. Chim. Sucr. Dist., 1906, **23**, 1148—1166.

L methods for the pyknometric determination of the ume or weight of precipitates suspended in any liquid, uire, as a necessary condition, that there should be no sotive accumulation or absorption of any of the disved substances, or solvent, on the surface of the precipie. The present method is based on the fact that if the ve condition be fulfilled, an intimate proportionality sts between the weight of the precipitate and the differe between the density of the mixed system and that the clear filtrate.

Thus: $p=(D-d')V\times k$, where p = the weight of the cipitate, D = the density of the mixture (liquid and cipitate), d′ = the density of the clear filtrate, V = the al volume, and k = a constant which has to be determined for any given precipitate. The value of

$$k=\frac{p}{(D-d')V}$$

ndependent of the concentration, but decreases as the sity of the precipitate increases. When the density the precipitate is not known, its volume is calculated m the expression

$$v=V-\frac{P-p}{d'}$$

ere v = the volume of the precipitate and P = the total ight of the mixture. On testing the method for the ermination of the values of k, it was found that accurate ults were obtained for lead sulphate, barium sulphate, oric hydroxide (when precipitated in presence of a nute proportion of sugar), and aluminium hydroxide, in the case of calcium oxalate, the method gave very oneous results, owing to a considerable adsorption of dissolved salts by the precipitate. The authors ve drawn a curve illustrating the connection between values of k and the densities of the precipitates; y hope to extend the method to the determination of the ume of the precipitates formed in saccharine solutions various defecating agents.—J. F. B.

ine titrations; "Back reactions" in ——. J. H. Davies and E. P. Perman. Chem. News, 1906, **93**, 225.

the titration of solutions containing iodine by thiosulphate or arsenious acid, using starch as indicator, the end-point of the reaction is frequently uncertain owing to the reappearance of the blue colour on standing for a short time. This "back reaction" is most marked when the iodine has been set free by copper sulphate or potassium bichromate, and is due to the comparative slowness (and incompleteness) of the liberation of iodine from dilute solutions of potassium iodide by these substances. If the concentration of the iodide solution be increased, the reaction becomes nearly instantaneous, and the "back reaction" is avoided. Suitable quantities of potassium iodide are 1 grm. in 10 c.c. of water for 25 c.c. of N/10 solution of potassium bichromate, and 2 grms. in 20 c.c. of water for 1 grm. of copper sulphate crystals in 50 c.c. of water.—A. S.

ORGANIC—QUANTITATIVE.

Ebonite; Analysis of ——. R. Thal. Chem.-Zeit., 1906, **30**, 499—501.

THE ash and total sulphur are determined in the usual manner.

Resin and substitute are determined together. One grm. of ebonite is boiled under a reflux condenser for four hours, with 100 c.c. of 8 per cent. alcoholic caustic soda. The residue is thoroughly washed with hot water, and weighed on a tared filter after drying at 100°—105° C. Blanks are necessary to ascertain the extracting effect of the alcoholic caustic soda on the filter and on the free sulphur in the ebonite, and the amount of soda retained by the ebonite.

Ebonite cannot be dried for more than two hours without gaining weight by oxidation. Good surgical ebonite should not contain more than 0·6 per cent. of ash, and the fact that samples exceeding this limit fail to yield clear solutions in nitric acid, affords a useful preliminary test.—W. A. C.

Saccharose and raffinose in presence of invert sugar and dextrose; Determination of ——. H. Pellet. Bull. Assoc. Chim. Sucr. Dist., 1906, **23**, 1140—1141.

THE reducing sugars of molasses may be composed of varying proportions of dextrose and levulose, sometimes one being in excess and sometimes the other. Fogelberg has proposed a method for the determination of the saccharose and raffinose, which is quite independent of the relative proportions of dextrose and levulose in the reducing sugars, since all these sugars are eliminated by the destructive action of alkali. For this purpose he employs barium hydroxide at the rate of 12 grms. for half to twice the normal weight of molasses. The materials are mixed with 120—130 c.c. of water, and the whole is heated on the water-bath at the boiling temperature for 10—15 minutes, whereby the reducing sugars are entirely destroyed. The liquid is then cooled, neutralised with acetic acid, decolorised with a little hypochlorite, and diluted to 200 c.c. The saccharose and raffinose are then determined by polarisation before and after inversion. Grzybowski has modified this method by precipitating the baryta by mercuric sulphate and the excess of mercury by a tin salt. The author points out that he proposed a similar method for the destruction of the reducing sugars by means of potash (see this J., 1898, 187).—J. F. B.

Oil of mustard; Determination of allyl isothiocyanate in essential ——. Schimmel's Report, May, 1906, 45—46.

THE official process of the Ph.G. IV. for the determination of allyl isothiocyanate in mustard oil gives results which are about 8 per cent. too low, so that no essential oil of mustard can meet the German official requirements. More accurate results are obtained by the following method:—

About 5 grms. of a 2 per cent. by weight solution of the oil in alcohol are treated with 50 c.c. of N/10 silver nitrate solution and 10 c.c. of solution of ammonia (sp. gr. 0·960) in a 100 c.c. flask. The mixture is allowed to stand in the dark, after closing the flask, for 24 hours. The flask is then immersed in a water-bath at 80° C. for 30 minutes, with frequent agitation, and subsequently cooled to the normal temperature. After adjusting the volume of the solution to 100 c.c. by the addition of distilled water, 50 c.c. are filtered off, and titrated in the usual manner

with N/10 ammonium thiocyanate solution, after adding 6 c.c. of nitric acid, sp. gr. 1·153, employing iron alum as indicator.

When a = the number of c.c. of N/10 silver nitrate solution used up, and b = the weight of alcoholic solution of mustard oil taken, $\frac{a \times 24.7875}{b}$ = the percentage of allyl isothiocyanate present.

Natural mustard oil should give about 94 per cent. by this method, the synthetic oil about 98 per cent.

—J. O. B.

Chloroform; Determination of alcohol in ——. M. Nicloux. Bull. Soc. Chim., 1906, **35**, 330—335.

Five c.c. of the chloroform under examination are agitated with 20 c.c. of water, and the alcohol determined in the aqueous extract by titration with potassium bichromate solution (19 grms. per litre) in presence of sulphuric acid, the end point of the reaction being detected by the change of colour of the solution from blue-green to yellowish-green.—T. F. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

(*Continued from page* 564.)

Platinum black; Some catalytic actions of ——. O. Loew and K. Aso. Bull. Coll. Agric., Tokyo, 1906, **7**, 1—6.

Experiments with a very active preparation of platinum black, obtained by treatment of platinum chloride with formaldehyde in presence of a considerable quantity of alkali (see this J., 1890, 550), showed that platinum black is capable of effecting the transformation of labile compounds, *e.g.*, of maleïc acid into fumaric acid. The reducing action of platinum black upon nitrates in the presence of dextrose (this J., 1890, 634) is found to take place also with dilute free nitric acid. A solution of 2 grms. of dextrose in 100 c.c. of water was treated with 2 c.c. of dilute nitric acid (0·08 grm. of HNO_3) and 10 grms. of platinum black, and heated on the water-bath for three hours. On distillation with magnesia, 0·012 grm. of ammonia was obtained. In another trial 0·049 grm. of ammonia was obtained from 2 c.c. of nitric acid of sp. gr. 1·3, 10 c.c. of water, 5 grms. of dextrose, and 10 grms. of platinum black. Chlorates, perchlorates, and iodates are also reduced by platinum black in presence of dextrose, chlorides and iodides respectively, being produced. It has been shown previously that platinum black, moistened with pure caustic potash solution forms traces of nitrous acid and ammonia from the nitrogen of the air (see this J., 1890, 979). After similar experiments with distilled water in place of caustic potash solution, traces of ammonia and of nitric acid (probably by oxidation of nitrous acid) were detected.—A. S.

Hexamethylethane, a new octane. L. Henry. Comptes rend., 1906, **142**, 1075—1076.

Hexamethylethane, $(CH_3)_3C.C(CH_3)_3$, is obtained as a by-product in the preparation of pinacolic alcohol by the action of acetaldehyde on tertiary butyl magnesium bromide. It is evidently formed without the intervention of the acetaldehyde, merely by the reaction of the butyl bromide with its own magnesium compound. It is a well crystallised body, with a sharp and very penetrating odour. It evaporates rapidly on exposure to the air, its vapour tension at 14° C. being equal to 20 mm. of mercury. It melts at 103°—104° C., and boils at 106°—107° C. under a pressure of 765 mm.

Cholesterol; Halogen derivatives of ——. J. Mauthner. Monatsh. Chem., 1906, **27**, 305—314.

It was shown by Suida and the author (Monatsh. Chem., 1894, 374) that cholesterol and cholestene yielded crystalline chlorine derivatives on treatment with alcoholic hydrochloric acid, but the nature of the cholesterol compound was not determined owing to its composition being variable, and the readiness with which it decomposed. The author has now found that the hydrochloric acid combines with the double bond, forming addition compounds from cholesterol itself, cholesteryl chloride, and cholestene. *Chlorcholestanol* (cholesterol hydrochloride), $C_{27}H_{45}ClO$, crystallises in fine silky needles, melting at 154°—155° C., with the evolution of gas. It is fairly soluble in chloroform, ether, benzene, and carbon bisulphide; less soluble in alcohol. *β-Dichlorcholestan*, $C_{27}H_{44}Cl_2$, crystallises from the mother liquor after separation of the chlorcholestanol, being formed by the replacement of the hydroxyl group in the chlorcholestanol by chlorine. It melts at 117° C., and is readily soluble in ether, benzene, chloroform, and carbon bisulphide, and with more difficulty in alcohol. It is slowly attacked by cold sulphuric acid, but is not acted upon by fuming nitric acid. *Chlorcholestan* (cholesteryl chloride) is obtained in flat prismatic crystals by the action of gaseous hydrochloric acid on a solution of cholestene in chloroform. It begins to melt at about 80° C., and is completely fused at 91° C., becoming crystalline again on cooling. Its solubility in ordinary solvents is similar to that of β-dichlorcholestan. It melts to a colourless oil in boiling alcohol.—C. A. M.

Trade Report.

South African Customs Union Convention. [Cd. 2977.]

The Customs Union Convention provisionally agreed to by the representatives of the South African Customs at a Conference held at Pietermaritzburg in March, 1906, was presented to both Houses of Parliament last week, and has been published by the Stationery Office. The following is an abstract:—

Class I.—*Special Rates.*

—		Rebate upon Goods the Growth, Produce, or Manufacture of the United Kingdom and Reciprocating British Colonies.
	£ s. d.	£ s. d.
Acetic acid ..... per Imp. gall.	0 3 3	0 0 3
Lard, including compound lard, cottolene, nuttose, and other similar substances for use as food....per lb.	0 0 1½	0 0 0½
Milk, condensed, desiccated, or preserved milk or cream—		
(*a*) Full cream .....per 100 lb	0 5 2	0 1 0
(*b*) Skimmed or separated .per lb.	0 0 6	—
Oils, mineral, illuminating and burning ..... per Imp. gall.	0 0 1	—
Soap, soap powders and extracts per 100 lbs.	0 4 9 (or 25 per cent. *ad valorem* whichever shall be the greater)	0 0 7 (or 3 per cent. *ad valorem* as the case may be)
Turmeric.....per lb.	0 0 2½	0 0 0½
Spirits—		
(*a*) Perfumed .... per Imp. gall.	1 2 6	—
(*b*) Liqueurs, cordials and mixed spirits, exceeding 3 per cent. of proof spirit .... per Imp. gall.	1 0 0	—
(*c*) Other sorts, exceeding 3 per cent. of proof spirit, per Imp. proof gall.	0 19 0	—
Note.—No allowance will be made for underproof in excess of 15 per cent.		
Note.—Medicinal and toilet preparations and essences (liquid), and syrups and tinctures containing over 3 per cent. of proof spirit to be classed as spirits under item (*b*).		
Blasting compounds.....per lb.	0 0 2½	0 0 0½
Candles .....per 100 lb.	0 5 0	0 0 10
Cement .....per 400 lb.	0 1 3	0 0 3
Gunpowder and other explosives for firearms.....per lb.	0 0 6 and 15 per cent. *ad valorem*	3 per cent. *ad valorem*

CLASS II.—25 *per cent. ad valorem.*

Beverages:—

(*a*) Waters, aerated, mineral, and table.

(*b*) Fruit juices, cordials, and syrups not elsewhere enumerated.

(*c*) All other kinds not exceeding 3 per cent. of proof spirit.

CLASS III.—25 *per cent. ad valorem.*

Extracts and essences of all kinds for food, flavouring, or perfumery not elsewhere enumerated, including concentrated soup.

Oils, essential or perfumed, including eucalyptus.

CLASS IV.—3 *per cent. ad valorem.*

Ammonia, anhydrous, carbonate, chloride (sal ammoniac) and nitrate, in bulk.

Assay apparatus and assay mabor.

Barytes and pumice in bulk.

Calcium carbonate, caustic, chloride, chlorate, bisulphate (in bulk).

Carbonic-acid gas.

Collodion, cotton, and glycerin, and kieselguhr in bulk for manufacturing purposes.

Confectioners' requisites—*viz.*, glucose, moulding-starch, gelatin, and unsweetened desiccated cocoanut in bulk.

Crucibles.

Cyanide of potassium and sodium, sulphocyanide of potassium, sodium, and calcium.

Disinfectants in bulk (provided they are of a standard approved by the various Governments of the Union).

Glue in bulk.

India-rubber, manufactured.

Magnesium sulphate in bulk.

Potassium and sodium carbonate, bicarbonate, caustic and silicate, chlorate, chloride, bichromate, permanganate, red and yellow prussiate (in bulk).

Resin in bulk.

Sheep-dip, sheep-dipping powders, materials suitable only for dip and dipping-tanks.

Substances for destroying pests or diseases in stock, such as copper sulphate, arsenic, arsenious acid, arseniate of soda (in bulk).

CLASS V.—*Free.*

Included in this are: Alum, borax, bromine, litharge, manganese dioxide, mercury (all in bulk), dye nuts, gambier, myrabolans, sumach, valonia, and dyestuffs for leather; guano and other substances, animal, mineral, or vegetable, artificial or natural, suitable for use as fertilisers or manures; nitrates in bulk (except nitrate of ammonium) for manufacturing purposes or for fertilisers; palm oil, palm-kernel oil, cotton-seed oil (in bulk); chloride of platinum, sulphur (in bulk), sulphurous anhydride, paraffin wax and stearin, and stearin grease for use in the manufacture of candles or explosives.

JAPANESE TARIFF; NEW ——.

Chem. and Drug., June 2, 1906.

The following is an excerpt from the new Japanese Import Tariff, which comes into force on October 1st next:—

EGYPTIAN VALUATION TARIFF.

Bd. of Trade J., June 7, 1906.

"The Egyptian "Journal Officiel" for May 19, contains the following revised Valuation Tariff for use in assessing import duties on certain oils, colours, &c., which came into operation on May 22:—

Articles.	Valuation per kilo. (net).*
	Millièmes.†
Cotton-seed oil, "prime winter yellow"	22
" " refined and "summer yellow"	20
Linseed oil, raw	21
" " boiled	22
Zinc white (first quality), including "Vieille Montagne"	26
Zinc white (second quality), including "Nouvelle Montagne"	*ad val.*
Red lead	19
Cochineal	*ad val.*
Cocoanut oil, raw or refined	"

* Duty is levied on these valuations at the rate of 8 per cent.
† 1000 millièmes = £E 1 = 1*l.* 0*s.* 6*d.*

BORDEAUX; TRADE OF —— IN 1905.

For. Off. Ann. Series, No. 3616.

The amount of pure olive oil exported from Bordeaux in 1905 was 29,979 cwts., an increase of 2,507 cwts., 9,794 cwts. being sent to the United Kingdom against 9,486 cwts. of 1904. Ground nut or "Arachide" oil showed an increase as compared with 1904 of 11,365 cwts., the total exported being 38,126 cwts., of which 15,606 cwts. were sent to the United Kingdom, an increase from 1904 of 2,731 cwts. Oils other than pure olive and ground nut oil, were exported to the total of 12,633 cwts., being a small increase upon 1904. Hardly any of these found their way to the United Kingdom.

Exports of raw sugar in 1905 amounted to 29,225 cwts., or more than double the trade in 1904; of refined sugar to 80,170 cwts., a decrease of 9,415 cwts. Exports to the United Kingdom showed an increase compared with 1904 of 5,025 cwts. of raw sugar and a falling-off of 2,867 cwts. of refined. The entire amount exported to the United Kingdom in 1905 was:—Raw sugar, 8,233 cwts.; refined, 10,367 cwts.

The following table shows the most important chemical products exported in 1904—05:—

Articles.	Total.		Increase or decrease in 1905.	United Kingdom.		Increase or decrease in 1905.
	1904.	1905.		1904.	1905.	
	Cwts.	Cwts.	Cwts.	Cwts.	Cwts.	Cwts.
Acids	21,402	31,629	+ 10,227	9,130	4,060	— 5,070
Oxides	4,804	5,157	+ 353	985	2,486	+ 1,503
Salts, &c.	18,170	32,164	+ 13,994	1,903	24	— 1,879
Acetate of copper	2,835	1,861	— 974	587	317	— 270
Glycerin	5,044	7,016	+ 1,972	1,126	2,880	+ 1,754
Kermes (mineral)	1,216	3,086	+ 2,870	25	20	— 5
Wine lees	2,028	8,250	+ 6,222	1,057	2,325	+ 1,268
Crude tartar	38,147	67,759	+ 29,612	20,774	30,380	+ 9,606
Cream of tartar	33,974	50,974	+ 17,000	30,076	46,194	+ 16,118
Superphosphate of lime	28,574	192,286	+ 163,712	—	—	—
Tannin extracts	280,646	347,340	+ 66,694	206,129	266,005	+ 59,876

Exports of gums in 1905 amounted to 28,655 cwts., an increase upon 1904 of 2,911 cwts. The quantity purchased by the United Kingdom was 12,082 cwts., a decline compared with 1904 of 2,970 cwts.

Exports of resin and pitch in 1905 amounted to 898,458 cwts., an increase of 563,039 cwts. upon the figures for 1904. Of this the United Kingdom purchased to the amount of 332,798 cwts., an increase compared with 1904 of 197,705 cwts. The demand for common strained resin was good, the article being somewhat difficult to obtain in October. Turpentine exports in 1905 were estimated at 145,250 cwts., an increase from 1904 of 97,036 cwts. The United Kingdom purchased 35,864 cwts., compared with 8,518 cwts. in 1904. The market in this commodity was most unsteady and excited. The amount of vegetable tar exported in 1905 was 2,174 cwts., a decline from 1904 of 5,422 cwts. Exports to the United Kingdom showed a falling off of 4,742 cwts., the total being 1,034 cwts.

Arsenic is manufactured near Carcassonne and shipped to the United Kingdom *via* Bordeaux. The amount exported was 3,165 tons, an increase of 2,950 tons upon 1904. Of this amount 2,615 tons were purchased by the United Kingdom.

Shipments of porcelain from Bordeaux in 1905 showed a decline of 3,518 cwts. compared with 1904, the total exportation being 84,785 cwts., of which 67,598 cwts. were sent to the United Kingdom, a falling off from 1904 of 5,280 cwts. Pottery and faïence had also declined, the total exported under this head in 1905 being 5,963 cwts. In the exportation of glass (chiefly bottles), there was an increase for 1905 of 38,828 cwts., the total amounting to 292,174 cwts., of which 53,134 cwts. were taken by the United Kingdom.

New Books.

THE ELEMENTS OF CHEMICAL ENGINEERING. By J. GROSSMANN, M.A., Ph.D., F.I.C. With a Preface by Sir William Ramsay, K.C.B., F.R.S. Chas. Griffin and Company, Ltd., Exeter Street, Strand, London. 1906. Price 3s. 6d.

8vo. volume containing 148 pages of subject matter, and the alphabetical index. There are 50 illustrations. The general treatment of the subject may be gathered from the sub-divisions of the text, which are as follows:—I. The Beaker and its technical equivalents. II. Distilling flasks; Liebig condensers; Fractionating tubes and their technical equivalents. III. The Air-Bath and its technical equivalents. IV. The Blowpipe and the Crucible and their technical equivalents. V. The Steam-Boiler and other sources of power. VI. Application of Heat in Chemical Engineering. VII. The Funnel, Mortar, Measuring Instruments, and their technical equivalents. VIII. Materials used in Chemical Engineering, and their Mode of Application. IX. Technical Research, and the Designing of Plant. X. Current prices of Chemicals and Materials.

REPORT ON THE INCIDENCE OF ANTHRAX IN THE MANIPULATION OF HORSEHAIR AND BRISTLES. By T. M. LEGGE, M.D., H.M. Medical Inspector of Factories. Wyman and Sons, Fetter Lane, E.C.

THE particulars contained in this Report with regard to the number of cases of anthrax due to the use of the materials (horsehair and bristles) during the last seven years show that the risk of infection to the persons employed in handling them is serious, and indicate the need for preventive measures being taken. The method by which the risk can be minimised by means of steam disinfection, is briefly described, and it is suggested that the process of disinfection could be most effectively,

and presumably most cheaply, carried out before the distribution of the raw materials to the manufacturer. The Secretary of State proposes to take into consideration the question of issuing Regulations under section 79 of the Factory and Workshop Act, prohibiting the use of dangerous classes of horsehair and bristles unless they have first been submitted to some efficient system of disinfection by steam; but before framing Regulations he would be glad to receive and consider any observations which manufacturers in the industries affected may desire to make, especially with regard to the suggestion mentioned.

FINAL REPORT OF THE DEPARTMENTAL COMMITTEE ON THE ROYAL COLLEGE OF SCIENCE, &c. Vol. II. Minutes of evidence, Appendices (II.—XIII.) and Index. [Cd. 2956.] Wyman and Sons, Fetter Lane, E.C. Price 1*s.* 11*d.*

A FOOLSCAP volume of 231 pages, containing minutes of evidence taken before the Departmental Committee of the Board of Education, 12 appendices on various allied subjects, and an index to the various subjects dealt with in the report, minutes and appendices.

JOURNAL OF THE

Society of Chemical Industry.

No. 13.—Vol. XXV. SUPPLEMENT. JULY 16, 1906.

HON. TREASURER:—
Samuel Hall, East London Soap Works, Bow, E.

PRESIDENT:—
Dr. Edward Divers, F.R.S.
GENERAL SECRETARY:—
Charles G. Cresswell.

EDITOR:—
Watson Smith, 34, Upper Park Road, Haverstock Hill, N.W

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie., 55, Rue des Francs-Bourgeois, Paris (3e).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy. A form of application for this purpose will shortly be issued.

Members are invited to call the attention of the Editor to any errors or omissions which they may have noticed in the Annual Indexes, 1896—1905, as soon as possible, in order that they may be put right in the Decennial Index.

List of Members Elected.

July 11, 1906.

Crowther, R. E., c/o Mark Fletcher & Sons, Ltd., Moss Lane, Whitefield, Manchester, Chemist.

Greene, George M., c/o Colgate & Co., Jersey City, N.J., U.S.A., Chemist.

Haefele, J. Ernest, 5, Marion Street, New York City, U.S.A., Chemist.

Henius, Dr. Max, 327, Fullerton Avenue, Chicago, Ill., U.S.A., Secretary, Brewers' School.

Herig, Harry W., 14, Van Houten Avenue, Jersey City, N.J., U.S.A., Chemist.

Hulme, Robert B., c/o Kentucky Refining Co., Louisville, Ky., U.S.A., Chief Chemist.

Johnson, Oliver L., Jewett City, Conn., U.S.A., Dye Works Manager.

Kremers, William, Holland, Mich., U.S.A., Sugar Mill Superintendent.

Morris, A. H., 77, Beverley Road, Bolton, Lancashire, Brewer.

Peverley, Frank, Holly Lea, Longfield Road, Urmston, near Manchester, Dyer.

Shaw, Ronald W. F., Hooghly College, Chinsurah, Bengal, India, Principal.

Sinclair, Edmund E., 3, Marion Street, New York City, U.S.A., Printing Ink Manufacturer.

Stokes, Francis J., 704, Locust Avenue, Germantown, Philadelphia, Pa., U.S.A., Manufacturing Chemist.

Wahl, Dr. Robert, 327, Fullerton Avenue, Chicago, Ill., U.S.A., President, Brewers' School.

Zdanowicz, Joseph, 5, Place de la Station, Alost, Belgium, Chemical Engineer (Artificial Silk).

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the Journal depends.

Baker, John T.; Journals to Phillipsburg, N.J., U.S.A.

Bartripp, G. F., l/o South Woodford; 20, Grove Road, Wanstead, Essex.

Benjamin, Albert A., l/o Bolton; Springbrook Works, Middleton Road, Oldham, Bleach and Dyeworks Manager.

Birwith, L. W., l/o Dover, N.J.; c/o E. I. du Pont and Co., Central National Bank Building, Wilmington, Del., U.S.A.

Brettell-Vaughan, E.; Journals to 18, Queen Street, London, E.C.

Breyer, Theodor, l/o Waukegan; 842, Lunt Avenue, Rogers Park, Chicago, Ill., U.S.A.

Broome, Jos., l/o Bayonne; 5, Webster Terrace, Roselle Park, N.J., U.S.A.

Buchanan, E. F., l/o Berlin; c/o Dresdner Bank, Frankfurt a/Main, Germany.

Davidson, C., l/o Pollokshields; 328, Golfhill Drive, Dennistown, Glasgow.

Dibdin, W. J., l/o Sutton; "Purley Bury," Purley Downs Road, Sanderstead, Surrey.

Duryea, C. B., l/o New York; c/o Edwardsburg Starch Co., Cardinal, Ont., Canada.

Evans, Sir John, K.C.B., F.R.S., l/o Hemel Hempstead; Britwell, Berkhamstead, Herts.

Fuller, C. J. P., l/o Brownlow Road; 603, Chorley New Road, Horwich, near Bolton.

Guthrie, Alan; Journals to c/o Cooper, Allen and Co., Cawnpore, India.

Hodgkins, D. H., l/o La Fayette Avenue,; 80, Paulison Avenue, Passaic, N.J., U.S.A.

Hudson, A. W., l/o Vancouver Island; retain Journals.

Jones, Chas. H., l/o Crouch End; c/o Capillitas Copper Co., Muschaca, near Andalgala, Prov. Catamarca, Argentina.

Labonde, Dr. Leon, l/o Rochester; Los Angeles, Cal., U.S.A.

Lachmann, Dr. Arthur, l/o San Francisco; Petaluma, Cal., U.S.A.

Lindsay, Robt., l/o Johannesburg; Cyanide Works, Durban Roodepoort G. M. Co., Roodepoort, Transvaal.

McGovney, C. S., l/o West La Fayette; Engineering Experiment Station, Urbana, Ill., U.S.A.

Matthews, Dr. J. Merritt, l/o South Street; 320, South Broad Street, Philadelphia, Pa., U.S.A.

Miller, J. Carlile, l/o Bridgeton; 188, St. Vincent Street, Glasgow.

Morris, Edgar F.; all communications to c/o Cornbrook Chemical Co., Ltd., Color Works, Stockport.

Myles, C. D.; Journals to Ossory Lodge, Kingstown, Co. Dublin.

Novarina, J. L., l/o Main Street; 289, Myrtle Avenue, Brooklyn, N.Y., U.S.A.

Payne, Allen G. C., l/o Peckham; 63, Plassey Street, Penarth, near Cardiff.

Proctor, C., l/o 27; 43a, London Road, Forest Hill, S.E.

Pullin, S. R., l/o Leeds; Attasi Mines, Prinsisu, Dunkwa Station, Sekondi, Gold Coast Colony.

Shuler, D. P., l/o Detroit; R.F.D. No. 7, Box 146, Los Angeles, Cal., U.S.A.

Siebold, Alf., l/o Alloa; c/o British Dyewood and Chemical Co., Ltd., Lacovia P.O., Jamaica.

Symmes, Whitman, l/o San Francisco; 2231, Piedmont Avenue, Berkeley, Cal., U.S.A.

Thompson, Dr. J. Fairfield, l/o New York; c/o Orford Copper Co., New Brighton, N.Y., U.S.A.

Tighe, Arthur, l/o Darling Point; Springfield, Darlinghurst Road, Sydney, N.S.W., Australia.

Walpole, G. Stanley, Journals to 140, Warwick Street, Pimlico, S.W.

Change of Address Required.

Pollitt, R. B., l/o Johannesburg.

Deaths.

Orsman, W. J., of Gathurst, Wigan; at Port Said. June 21st.

Russell, David, at Silverburn, Leven, Fife. June 2nd.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of Application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

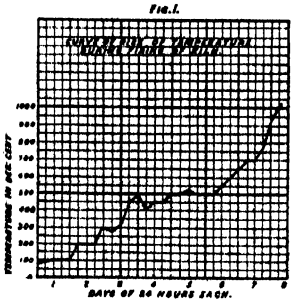
Meeting held at Birmingham on Wednesday, May 16th, 1906.

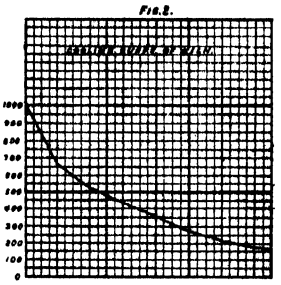
PROF. P. F. FRANKLAND, F.R.S., IN THE CHAIR.



SOME TEMPERATURE OBSERVATIONS DURING THE BURNING OF FIRE-CLAY GOODS.

BY WALTER C. HANCOCK, B.A. (CANTAB.), F.I.C.

Clays, in their natural state, contain both moisture and combined water. In the course of manufacture more water is introduced to render the clay plastic, but the bulk of this is removed during the drying process, and is accompanied by the contraction known as "air shrinkage." What little added water remains when the goods are ready for burning may be treated as "moisture." Moisture is driven off from clay at from 100° to 150° C; the expulsion of combined water begins at about 350° to 400° C. and is complete at from 600° to 700° C. By the determination of this "temperature of dehydration," according to Le Chatelier, hydrated aluminium silicates are capable of better classification than by chemical analysis. Le Chatelier has also shown that besides the usual absorption of heat on dehydration, which checks the rise of temperature, there is at certain temperatures, a brisk evolution of heat due to physical change. On heating, clays also lose carbon dioxide, sulphur dioxide, organic matter, &c. Kennedy (Transactions of the American Ceramic Society, 1902, 4, 146) found that pure kaolin briquettes up to 600° C. lost weight equally with briquettes of 70 per cent. kaolin and 30 per cent. chalk, but that the latter lost further in weight up to about 900° C., showing that the carbon dioxide was driven off between 600° and 900° C.



In order to follow the temperature changes occurring during the burning of an ordinary circular down-draught kiln, an electrical pyrometer was inserted in the centre of the crown of the kiln, and extended to a depth of about 1 ft. inside. Observations were recorded every two hours, with the results shown in Fig. 1.

FIG. 1.

The first reading was taken at 80° C., when the grates were half full and the top of the "wicket" still open. The fires in the grates were increased by regular additions to the top, and the temperature rose gradually to 500° C. At this point the top of the wicket was bricked up, and 1 in. of draught put on the chimney. The temperature then fell to 400° C., evidently due to insufficient draught. After 24 hours, however, with a 2-in. draught, the temperature of 500° C. was regained. For the next 32 hours the temperature of the kiln remained stationary at 500° C., although the firing was steadily maintained and the 3rd and 4th inches of chimney draught were added. This stationary temperature indicated absorption of heat, due to dehydration of the clay, and this observation, made on a kiln containing some 27 tons of material, practically confirms observations made on a laboratory scale by Le Chatelier and others. From this point the temperature rose steadily until the maximum of 1000° C. was reached. The readings of the electrical pyrometer corresponded fairly closely with the fusing points of

FIG. 2.

some Seger cones also contained in the kiln. Fig. 2 shows the cooling curve of the kiln.

An electrical pyrometer enables the changes occurring in the kiln to be followed without opening it. By its use the workman's attention to the firing can be checked, the supply of heat controlled, and the temperatures known at which absorption or disengagement of heat occurs. This critical temperature of dehydration should be known to all burners of clay articles as A. E. Barnes has already pointed out. In kilns closely set, as with bricks, a large quantity of steam is rapidly set free, and becomes in a measure superheated. The action of this steam upon the cooler parts of a kiln and the ventilation and construction of kilns to meet this emergency, all demand further study. With regard to some of the points here mentioned, the use of an electrical pyrometer would give information. At the same time, as Prof. H. Ries mentions in a report upon "The Clays and Clay Industry of New Jersey," the price, delicacy of the instrument, and lack of realisation of its importance, have all tended to restrict its use—though many of the larger clay-working plants of New Jersey are adopting it, an example, which from my own personal experience, I would commend to the careful consideration of English manufacturers.

My thanks are due to Messrs. Chance, Brothers and Co., Ltd., for kindly allowing the results of these observations, made on their works, to be published.

DISCUSSION.

Dr. SLATER PRICE asked if the curve obtained when the kiln was being heated up was the only one taken, or whether others had been taken, all showing a similar peculiarity at a temperature of about 500° C.

The CHAIRMAN asked whether a similar curve had been taken showing the effect of firing upon an empty kiln. Was it absolutely certain that the effect was entirely due to the charge?

Mr. ALEX. TUCKER said that he had seen, near Dusseldorf, an interesting control for high temperatures applied to a kiln, which depended on the flotation of a bar of iron in mercury. The mercury was placed in a by-pass from the main flue, and in this way the temperature to which it was exposed was reduced considerably. The iron bar actuated a differential valve as a kind of relay, and by a damper controlled the chimney outlet of the furnace, and so regulated the heat of the kiln.

Mr. ROSSITER asked whether any temperatures had been taken with the pyrometer in different positions in the kiln? He had had some experience in taking tem-

peratures in furnaces and he found there could be enormous differences in just shifting the pyrometer from one place to another; in fact, a small shift of the pyrometer would sometimes make a great difference in the temperature. It appeared to him that if a kiln were charged with a quantity of fire-clay goods, the temperature at the crown of the kiln, or 2 ft. below the crown of the kiln would be different from the temperature at the same time 2 ft. from the floor of the kiln.

Mr. PAGE said that the pyrometer was not placed in the most desirable position for the purpose. The fluctuations in the temperature of the fuses at this point were considerable, due to the conditions of "firing." The fire mouths had no doors, and the quantity of air admitted over the fire was very variable, and of course such variation would be very pronounced at the point where the pyrometer was placed. This would be evident had the sketch shown the relative position of the fire holes or furnaces of the pyrometer.

The question of dehydration had been dealt with recently by Mr. Jos. Burton in a paper read before the English Ceramic Society. The method he adopted was to burn small tiles (previously dried at 105° C.) to temperature intervals of 20° C., and so find the loss in weight. These experiments showed that the combined water was driven off as follows, taking each 40° interval:—120° C., 0·32 per cent. of the total combined water; 160° C., 0·51 per cent.; 200° C., 0·62 per cent.; 240° C., 0·67 per cent.; 280° C., 0·86 per cent.; 320° C., 1·40 per cent.; 360° C., 2·30 per cent.; 400° C., 2·82 per cent.; 440° C., 2·96 per cent.; 480° C., 4·24 per cent.; 520° C., 9·59 per cent.; 560° C., 10·18 per cent.; 600° C., 10·69 per cent.; 700° C., 11·15 per cent.; 800° C., 11·42 per cent.; and at 1200° C., 12·01 per cent.

The temperatures were taken with a carefully calibrated Le Chatelier pyrometer, and it would be noticed that nearly half of the combined water was driven off between 480° and 520°, which would agree with Mr. Hancock's conclusions. As to the fact that the temperature curve showed a retardation about 500°, this was fully recognised by a competent kiln man, and so far from trying to increase the temperature at this point, he kept the fire mouths open, thus admitting a large quantity of air over the fire, and made no attempt to force the heating until he was satisfied that the rush of this so-called "second steam" was past. The beginning and the end of this critical period were easily observed in cases where the ordinary down draught kilns had independent chimneys. The indication was the discharge from the chimney of a yellowish vapour. It was this vapour, too, which gave rise to the bluish haze often observed when one looked down on a brick yard lying in a valley or depression.

Mr. H. L. HEATHCOTE referred to a method of measuring the temperature in kilns and other hot places. Mr. Hancock had mentioned the well-known advantages of the pyrometer, but the pyrometer generally employed could not be moved about, and it measured the temperature at a particular place in the kiln. In conjunction with Mr. John Pugh, of the Rudge Whitworth Co., he had perfected a pyrometer which enabled one to tell the temperature quite accurately at any part of the kiln that could be seen from the outside—it was very simple and only involved the employment of solutions which were contained in glass cylinders half an inch in diameter and half an inch in thickness. These were so made and so composed that if one looked at a red hot body through a pair of these cells, it would be invisible because the light was entirely absorbed. If the hot body rose in temperature it would just become visible. These were so made, too, that they gave the same reading with another person's eyes, because the rods were not stimulated. A number of pairs could be placed in front of the eyes, which were protected from extraneous light by a stereoscope-like hood. Each pair corresponded to one temperature. The instrument could be hooked to the ears like spectacles.

Mr. L. ARCHBUTT asked whether Mr. Heathcote's pyrometer was made commercially, and where it could be obtained.

Mr. HEATHCOTE replied that the instrument was at present being perfected for other materials besides iron and steel, and that it would be put on the market, although not immediately.

Mr. W. C. HANCOCK, in reply, said that he was quite aware that there was one rather weak point in this communication, and that was that the curves which he had shown simply represented the observations upon one kiln. His explanation was that he was not now in a position to follow up the subject. With regard to the question as to what would be the variations of the pyrometer supposing the kiln to be empty, he had no data, as no such experiment had been tried, but he must say that he failed to see why for 32 hours that particular temperature should have been maintained, considering the fact that the amount of heat which was being communicated to the kiln was being continually increased. He was certain from personal observation of the kiln that it would not remain stationary from any actual neglect on the part of the workmen. He was exceedingly interested to hear of the instrument described by Mr. Tucker, and also of the method of measuring the temperatures, which was quite new to him; he should be very pleased to hear more of the matter. He was, of course, quite willing to admit the difficulties attending the use of this pyrometer, and the fact that it simply recorded the temperature of one point in the kiln. But he thought, regarding the symmetry of such a kiln, that the point he had chosen was the best at which to take the observations. He was fully aware of the difference which existed between the temperature at the top and the bottom of a kiln, but this kiln also contained a number of Seger cones which were placed on the top of some materials in the kiln, and consequently about 3 or 4 ft. lower than the junction of the thermo-couple, and the temperatures at which these cones fused corresponded fairly closely with the readings of the pyrometer. For example, a 01 cone, the fusing point of which is 920° C., was noticed to go down when the reading of the pyrometer was about 925°, and another cone corresponded pretty closely with 990° C. With reference to the method Mr. Page referred to, he himself had made some observations on a large scale in the same way. He could see no explanation for the curve remaining practically constant for 32 hours except that it was due to some physical change that was taking place in the materials in the kiln, and he was certainly confirmed in that opinion by the fact that on the laboratory scale Le Chatelier had obtained the same result. Of course he did not maintain that the temperature was accurate within a few degrees; it would vary with different clays, especially in the case of fire-clays, which were more complex than ordinary clays.

EFFECT OF CERTAIN ELEMENTS ON THE STRUCTURE AND PROPERTIES OF COPPER.

BY ARTHUR H. HIORNS.

Much work has been done in recent years in investigating the influence of various metals when alloyed with copper in different proportions, notably by Charpy, Stead, Le Chatelier, Gautier, Stansfield, Roberts-Austen, Baykoff, Heycock and Neville, Campbell, and the author. The present research has special reference to the alloys of copper with arsenic, antimony, bismuth, lead and phosphorus. Some of these alloys, viz., Cu-As, Cu-Sb, Cu-P, form chemical compounds, others exist as solutions, and some form mere mixtures or emulsions.

The mode of procedure was to melt pure copper and then add the alloying element. Two methods of treatment were employed, viz., the freezing point method and the microscopic examination of the alloys, one method confirming the results of the other.

For the preparation of the alloys carbon crucibles were employed. After melting the metals together they

were vigorously stirred with a charred stick, covered with powdered charcoal and a lid, and then allowed very slowly to cool. Another portion was cooled quickly. For microscopic examination a slice was cut right through the centre of the ingot, and the surface selected for polishing was that at right angles to the cooling surface. For obtaining the freezing point of a series the freezing points of the separate metals were first determined, and then that of the various alloys.

The types of pattern visible on the etched surface of the metal depend upon the position of the freezing-point on the curve. For alloys whose freezing-points are on or near the summit of a curve the whole of the section is composed of one substance, generally made up of crystal-grains having fine boundaries. When by the addition of either constituent a summit of a curve is left, the lines between the crystal-grains widen and become filled with a network of matter differing from that of the crystals and generally showing a more or less striated structure, characteristic of eutectics. As the bottom of a curve leading from a summit is reached, the eutectic occupies the whole surface. Any deviation from the eutectic proportion causes the breaking up of this striated pattern, and grains of one of the constituents appear in the eutectic matrix. The nature of these grains will depend on which side of the eutectic angle the alloy belongs to. These grains are primary bodies; they crystallise out first on the cooling of the alloy, and often arrange themselves in rows at right angles to each other, forming a dendritic structure. They are probably skeleton crystals, which are gradually filled up from the matrix by addition from one of the constituents as a true chemical compound or a pure metal is approached.

The freezing-points of the various alloys were determined by a protected thermo-junction, and the readings taken from a graduated scale.

Curves of freezing-points.—The curves recording the freezing-points are shown in Fig. 1. The composition is given in percentages. The alloys were analysed and micro-sections taken before and after the re-melting.

Arsenic.—The addition of arsenic lowers the melting point of copper uniformly down to 14 per cent., when a steep fall occurs, reaching its lowest point at 685° C. This alloy contains 19·2 per cent. of arsenic, which corresponds to the formula Cu_5As. The alloy with 22 per cent. of arsenic freezes at 708°, and the curve gradually rises until the alloy with 28·4 per cent. is reached at 747°. This is the chemical compound Cu_3As, and is distinguished by several characteristics, which will be referred to when describing the micro-sections.

At 847° C. another chemical compound freezes, having the formula Cu_5As_2, and containing 32·2 per cent. of arsenic. This is a well-marked body, as shown by its colour, fracture, melting point, and internal structure; it solidifies at one temperature like a pure metal. Beyond this proportion the temperature falls to a minimum with about 35 per cent. of arsenic. The curve then rises to another summit at 740° with 37·34 per cent. of arsenic, forming the compound Cu_2As. From this position the curve descends to 702°, with the alloy containing 41 per cent. of arsenic. This is near the practical limit of the direct combination of copper with arsenic.

The information furnished by the curve may be stated as follows: The line is practically straight from 0 to 14 per cent., then falls rapidly to the eutectic mixture B. At C, the first chemical compound, Cu_5As, crystallises out as a pure substance. This is soon followed by the compound Cu_5As_2 at D. At E another eutectic mixture occurs and at F we get the compound Cu_2As. Beyond G the constituents form mere mechanical mixtures, the arsenic rapidly burning off.

In Watts' Dictionary of Chemistry, vol. 2, 1882, it is stated that the chemical compound Cu_3As occurs native as domeykite in Chili and Cornwall. The compound Cu_2As is known as white copper or white tombac, obtained by heating an arsenite or arseniate of copper with charcoal. The compound Cu_2As_2 may be produced by passing arsenuretted hydrogen over dry cupric chloride.

Table of Alloys.

No.	Per cent. of arsenic.	Freezing point in degrees centigrade.	Notes.
1	0·1 to 0·2	Between 1060 and 1020	
2	0·3 to 0·4		
3	0·5 to 1·0		
4	2·0 to 3·0		
5	4·0 to 5·0	1010	
6	6·0 to 10·0	1000 to 965	
7	11·0 to 13·0	950 to 920	
8	13·0 to 15·0	920 to 900	
9	16·0 to 18·0	810 to 790	
10	19·2	685

17	41·0	702	
18	43·0	—	Extreme limit of combination.

Friedrich (Metallurge 2, 477, 1905), has investigated the alloys of copper and arsenic, and gives three eutectics and four horizontals in the cooling curve. The former at 688°, 711°, and 603°. He says the compound Cu_3As does not exist.

Antimony.—The addition of antimony to copper lowers the freezing-point more or less rapidly down to 31·5 per cent., when the eutectic mixture is formed, Fig. 1, H. As the antimony is increased above this limit the freezing-points rise in temperature, reaching a maximum at, I, with about 46 per cent. of antimony, which is midway between the compounds Cu_3Sb and Cu_2Sb. There should be a break in the curve in the points representing these compounds, but it is probably too small to be recorded by the instrument. The point, I, must consist of a solid solution which decomposes into two separate bodies on cooling to 410° C. Beyond the alloys with 50 per cent. of antimony the fall is continued to, J, with 75 per cent., which has the lowest melting point of the series, and is therefore the true eutectic mixture. With still more antimony the temperature rises until the freezing-point of pure antimony is reached at 632°.

The alloys of copper and antimony have been studied by Charpy, Stead, Le Chatelier, Stansfield, and Baykoff.

Baykoff (Soc. d'Encour. pour l'Indus., 1903) gives both micro-sections and cooling curves. He considers that the curve consists of four branches, each corresponding to a special solid phase. That the branch, I—J, has a slight arrest at 586°, corresponding to the transition of $SbCu_3$ into $SbCu_2$. His highest point is at 681° with the compound $SbCu_3$. This is not confirmed by the author's experiments. On cooling the alloys with 46½ to 32 per cent. of antimony, a low arrest at 410° is observed. The nearer the alloy approaches to $SbCu_3$ the longer are the arrests. The action is reversible, from which Baykoff concludes that $SbCu_3$ is dimorphous, and designates them as *alpha* and *beta* modifications. Alloys with excess of antimony contain crystals of the *beta* form.

Table of Alloys.

No.	Per cent. of antimony.	Freezing point in degrees centigrade.	Notes.
1	0·1 to 2·0	1080 to 1064	
2	0·2 to 5·0	1064 to 1025	
3	5·0 to 9·0	1025 to 970	
4	9·0 to 13·0	970 to 920	
5	15·0 to 19·0	905 to 863	
6	22·0 to 25·0	840 to 800

14	48·3	655	,, $SbCu_3$.
15	50·0 to 55·0	650 to 630	
16	55·0 to 60·0	630 to 600	
17	60·0 to 74·0	600 to 480	
18	75·0	470	The eutectic mixture.
19	76·0 to 97·0	480 to 595	
20	98·0 to 99·5	600 to 622	

Phosphorus.—According to Percy, copper is capable of taking up 11 per cent. of phosphorus, and this alloy is stated to be so hard that it can scarcely be touched with a file. This statement is not correct for the 11 per cent. P alloy, but it is true if applied to the 14 per cent. alloy, which is probably the one Percy must have tested. (Percy's Metallurgy I., 279.)

Abel obtained a greyish-black crystalline substance by passing hydrogen over monocupric phosphate, to which he gave the formula Cu_3P_2, and found that it changed to Cu_6P_2 on ignition. He also remarks that the 14 per cent. alloy, Cu_3P, is the highest phosphide of copper that can exist at a red heat. (Chem. Soc. J., xiv., 183.)

Rose obtained the compound Cu_3P_2 by passing phosphoretted hydrogen over heated cupric chloride, or through a solution of cupric sulphate. He also obtained the compound Cu_3P by passing phosphoretted hydrogen over cuprous chloride or sulphide. (Pogg. Ann., xiv., 188; xxiv., 321.)

Since Abel's time great attention has been given to the preparation of phosphor-copper for commercial purposes, especially by Dr. Kunzel, but, so far as the author is aware, no elaborate research giving the freezing-points and micro-structure has been printed.

The freezing-point curve shows that phosphorus rapidly lowers the freezing-point of copper, reaching a minimum at the point, P, with 8·21 per cent. phosphorus. With an increase of phosphorus beyond this limit the temperature gradually rises, reaching a maximum at, R, with 14 per cent. phosphorus. As this is the saturation point of phosphorus in copper no further tracing of the curve is possible.

Table of Alloys.

No.	Freezing points in degrees centigrade.	Per cent. phosphorus.	Notes.

13	860	11·30	
14	950	12·00	
15	990	13·00	
16	1005	14·00	Cu_3P.

Bismuth.—From A, the freezing-point of pure copper, the curve falls gradually to 868° with 57 per cent. of bismuth. This forms a transition point, beyond which the curve forms a nearly horizontal line till about 70 per cent. is attained. In this region two possible chemical compounds may be present, viz., Cu_3Bi_2 at 68·64 per cent., and Cu_2Bi at 62 per cent., but there are no well marked indications of such, either in the freezing-point curve or in the micro-sections. The point, M, is the transition point between solutions of bismuth in copper and copper in bismuth, and at this point the two solutions probably have the same freezing-point, forming a mixture, which here exists in equilibrium.

It may be remarked that the solid solutions are only constant for a given temperature, so that the constitution of these alloys undergoes continuous variation, especially as the miscibility is necessarily restricted. With regard to the freezing-point curve, it may be noted that the liquid portion is not in equilibrium with a pure metal except in the branches A M and N O. The solid component copper can dissolve the component bismuth until the concentration of the latter has reached a certain value as given by the transition point, M. Addition of a further amount of bismuth may not alter the composition of the solid solution, but there will be formed a second solid solution, consisting of a solution of copper in bismuth, and at, M, we have the three phases—solution with excess of copper; solution with excess of bismuth; and copper. It is probable that in most of the copper-bismuth alloys, the solid solutions which are deposited from the liquid mass, lose their homogeneity at lower temperatures, even when quickly cooled. With regard to that branch of the curve which contains 60 to 70 per cent. of bismuth, it is possible that the compounds Cu_3Bi_2 and Cu_2Bi may be formed, but can only exist in contact with solutions containing excess of bismuth. As the temperature falls the compounds are converted into another solid phase.

Table of Alloys.

No.	Freezing point in degrees centigrade.	Per cent. of bismuth.	Notes.
1	1075 to 1055	1 to 5	
2	1030 to 1000	10 to 20	
3	985 to 940	25 to 40

5	880	52·3	Possible compound Cu_3Bi.
6	875 to 860	55 to 60	
7	858	62·1	Possible compound Cu_2Bi.
8	850	68·64	Possible compound Cu_3Bi_2.
9	850 to 820	70 to 80	
10	775	85	
11	700 to 600	90 to 95	
12	245	97·2	Eutectic mixture.
13	250 to 255	98 to 99	

Lead.—When lead and copper are melted together, well stirred, and allowed slowly to cool, a separation of the two constituents takes place; one, a rich alloy of copper containing a little lead, the other a rich alloy of lead containing a little copper. If the alloys are poured into an iron mould and quenched in cold water on solidification an apparently homogeneous product is obtained in the alloys from 0 to 50 per cent. of lead. The freezing-point curve shows that lead gradually lowers the freezing-point of copper down to about 40 per cent. of lead, and that from about 45 to 80 per cent. of lead the curve only deviates a little from the horizontal. There is no chemical compound nor eutectic mixture.

The curve indicates a series of solid solutions, the components of which are copper and lead. In all the alloys from 5 to 98 per cent. of lead there is a second arrest in the cooling at about 326° C., due to the separation of pure lead.

Heycock and Neville (Phil. Trans., 189, 1897) state that in alloys with 40 to 86 per cent. of lead the curve forms a straight line, the freezing-point being constant at 954°. This does not accord with the results obtained in the present investigation, although the deviation is not great, yet a slight gradual fall over this range was obtained. They consider that the sloping parts of the curve correspond to the separation of solid matter from a homogeneous liquid, and that in alloys on the flat portion the liquid separates into two conjugate liquids at some temperature above the freezing-point, consequently these alloys are qualitatively identical, and, therefore, freeze at the same temperature.

Gautier (Soc. d'Encour., Oct., 1896) gives a curve showing eutectics at 50 and at 0·15 per cent. of copper, but this is evidently incorrect.

Table of Alloys.

No.	Freezing point in degrees centigrade.	Per cent. of lead.	Notes.
1	1076 to 1020	1 to 20	From 95 per cent. Cu down to 0 per cent. there is a second freezing-point at 326° C.
2	990 to 960	30 to 45	
3	960 to 940	45 to 70	
4	930	80	
5	880 to 845	90 to 95	
6	780 to 500	97 to 99	

Microscopic study of the alloys.—The sections selected for examination were usually transverse, and cooled very slowly. Some were also cooled quickly for purposes of comparison, or in order to fix the condition prevailing at the freezing-point.

The photo-micrographs were taken with an arc lamp, and the illumination in the microscope was normal. The descriptions which follow are based on what was visible under the microscope rather than on the photographs. For one thing, the photographs cannot show the delicate tints of colour that are a striking feature of many copper alloys.

Arsenic.—The polished sections when viewed in full daylight are all copper coloured in those with little arsenic and gradually get paler as the arsenic is increased. When the 19·2 per cent. alloy is reached the surface shows a pale blue colour, and this is continued up to the compound Cu_3As with 28·34 per cent. of arsenic, which is of a deeper blue colour. The alloy with 30 per cent. of arsenic is of a light purple colour, and when the compound Cu_5As_2 is reached, containing 32·2 per cent., a full reddish-purple colour is obtained, and this colour prevails up to the limit of these experiments with 43 per cent. of arsenic, but gets gradually paler.

The chemical compounds referred to above have a structure more or less uniform, and differ from the intermediate alloys. In most of the alloys the structure is revealed by simple polishing, but intensified by the etching liquid.

The following is a detailed description of the various alloys. From 0·5 to 19 per cent. the grains become gradually smaller, and the structure finer in appearance. The compound Cu_5As_2 is entirely crystalline and this kind of structure prevails up to the limit of these experiments.

0·1 *to* 1 *per cent. of arsenic.*—These alloys consist of dark coloured grains of nearly pure copper, bounded by a lighter coloured but harder material, which is probably a solid solution of arsenic in copper, and structureless. Fig. 2 contains 0·5 per cent. of arsenic.

2 *to* 5 *per cent. of arsenic.*—The grains are smaller and lighter coloured than the preceding ones and more oxidisable. The boundaries are wider, more irregular in shape, and in their interior a new structureless constituent of a pale blue colour appears, evidently due to decomposition of the substance of the boundaries. This is probably the compound Cu_3As.

6 *to* 13 *per cent. of arsenic.*—The light coloured solid solution now ceases to enclose grains and forms a matrix, through which branching masses of the blue compound are distributed. Fig. 3 contains 7 per cent. of arsenic.

14 *to* 18 *per cent. of arsenic.*—The solid solution not only contains masses of the blue compound, but assumes a roughly striated appearance, made up of the solid solution and the blue compound. The portions occupied by the compound are also striated in the usual manner of a eutectic mixture. Fig. 4 contains 17 per cent. of arsenic.

19·2 *per cent. of arsenic.*—This is the eutectic mixture of the compound Cu_3As and the solid solution. Fig. 5.

20 *to* 27 *per cent. of arsenic.*—The compound now crystallises out from the eutectic mixture and increases in amount until at 27 per cent. only a small portion of this eutectic is seen. Fig. 6 contains 23 per cent.

28·34 *per cent. of arsenic.*—This alloy differs entirely from all the preceding ones in being of a deeper blue colour and much more brittle. The surface is structureless and contains many cracks. Fig. 7. It is the chemical compound Cu_3As.

32·19 *per cent. of arsenic.*—This is the reddish-purple compound Cu_5As_2. It is composed of large crystals, in the interior of which are a number of smaller ones, which are probably secondary crystals, and in each of these are fine lines, assumed to be lines of cleavage. This is shown in Fig. 8.

33 *to* 36 *per cent. of arsenic.*—The purple compound largely occupies the ground, being the first to crystallise out, but a eutectic mixture is also present and increases in quantity with increase of arsenic. It is composed of alternate striæ of white and purple, that is, of the white compound Cu_2As and the purple compound Cu_5As_2. Fig. 9 contains 34 per cent. of arsenic.

37·24 *per cent. of arsenic.*—This is the nearly white compound Cu_2As. It is composed of structureless grains of irregular shape. Fig. 10.

39 *to* 41 *per cent. of arsenic.*—This section is composed of pale purple grains, surrounded by a eutectic mixture of pale purple and black striæ, which in the 41 per cent. alloy occupies about one-third the ground. Fig. 11.

43 *per cent. of arsenic.*—This is the limit of combination of arsenic with copper by direct union. Much of the surface is covered with a eutectic mixture. It probably contains the compounds Cu_2As and Cu_3As_2, but the latter compound I have not been able to produce. It may be a mechanical mixture of different bodies.

Antimony.—With respect to the micro-structure of this series, Stead (J. Soc. Chem. Indus., Dec., 1898) and Charpy (Soc. d'Encour. pour l'Indus., 1897) differ with regard to the alloys near the intermediate summit of the freezing-point curve. Charpy gives the alloy with about 60 per cent. of copper as Cu_2Sb, while Stead rightly gives it as 51·5 per cent.

Baykoff has gone further than the above authorities, and gives both micro-sections and cooling curve. He states that alloys with 0 to 51 per cent. of copper have all the same structure whether cooled quickly or slowly. That alloys with more than 51 per cent. differ with the rate of cooling. That quenched alloys with 53½ to 69 per cent. have the same structure when suddenly cooled. That alloys with more copper have a heterogeneous structure with the exception of the alloy $SbCu_3$, which is homogeneous whether cooled quickly or slowly. That the effect of quenching depends on two transformations—the decomposition of solid solutions (separation of $SbCu_3$) and of the polymorphism of $SbCu_3$. (Soc. d'Encour. pour l'Indus., 1903.)

Polished sections of copper-antimony alloys are all copper coloured from 0 to 15 per cent. of antimony. With 17 to 30 per cent. a bronze colour prevails. From 32 to 38·7 per cent. the colour is a pale blue. From 39 to 59 per cent. the colour is purple, with its deepest tint at about 49 per cent. and palest at 59 per cent. With more antimony than this the colour is greyish-white with a bluish tint.

The following is a detailed description of the alloys examined:—

0·1 *to* 1 *per cent. of antimony.*—The structure consists of dark polygonal grains of nearly pure copper, bounded by a lighter coloured and harder material. In the centre of these boundaries a whitish substance is present forming in some parts a division and has probably separated during slow cooling. The antimony evidently exists in the boundaries in solid solution, and this white substance may be segregated antimony. Fig. 12 contains 0·4 per cent. of antimony.

2 *to* 16 *per cent. of antimony.*—The grains are irregular in shape and the boundaries contain a bluish-grey constituent in isolated patches, which are composed of the compound Cu_3Sb separated from the solid solution. This compound increases in quantity with increase of antimony. Fig. 13 contains 9 per cent. of antimony.

17 *to* 28 *per cent. of antimony.*—A change now occurs in the colour of the polished sections owing to the greater preponderance of the bluish-grey compound, which gets paler in colour as the antimony increases. The surfaces of the sections are seen to consist of two constituents, the grey compound and the solid solution.

28·5 *to* 30 *per cent. of antimony.*—The grey compound occupies the greater part of the surface in which the solid solution of antimony in copper appears in the form of dendrites. Fig. 14 contains 30 per cent. of antimony.

31 *to* 32 *per cent. of antimony.*—The surface is largely covered with a eutectic mixture, composed of $SbCu_3$ and a solid solution. Fig. 15.

33 *to* 37 *per cent. of antimony.*—The grey compound occupies the greater part of the field with some patches of eutectic, which is composed of the grey compound and a white constituent, which turns to a light purple on etching with hydrochloric acid. These alloys are extremely brittle. Fig. 16 contains 34 per cent. of antimony.

38·64 *per cent. of antimony.*—This is an extremely brittle alloy, of a light grey colour, and having dark

boundary lines surrounding the grains. It is the chemical compound Cu_2Sb.

40 *to* 47 *per cent. of antimony.*—The alloys now assume a purple tint increasing in intensity as the antimony is increased up to a maximum at 48·5 per cent. In the 40 per cent. alloy the grains are bounded by white lines. As the antimony increases the grains become less and interspersed with more and more of a eutectic mixture, Fig. 17, with 46 per cent. of antimony, consists almost entirely of a eutectic mixture of the two compounds Cu_2Sb and Cu_2Sb.

48·5 *per cent. of antimony.*—This is the well-known purple alloy termed "Regulus of Venus." It is the compound Cu_2Sb. It is structureless and very brittle.

49 *to* 56 *per cent. of antimony.*—These alloys consist of purple elongated grains bounded by white lines. The grains are the compound Cu_2Sb and the white lines a solid solution of copper in antimony. Fig. 18 contains 56 per cent. of antimony.

61 *to* 73 *per cent. of antimony.*—The purple compound now forms straight bands running across the surface in different directions. The matrix consists of more or less triangular patches of a eutectic nature, composed of the compound Cu_2Sb, and the white solid solution. White lines also traverse the purple bands, as seen in Fig. 19, with 63 per cent. of antimony.

75 *per cent. of antimony.*—The whole surface is composed of a eutectic mixture of Cu_2Sb, and the white solid solution. Fig. 20.

76 *to* 99 *per cent. of antimony.*—The white solid solution now separates in larger and larger crystals, as seen in Fig. 21 with 90 per cent. of antimony. That the white body is a solid solution and not pure antimony is indicated by the fact that brown specks appear on the white surface after oxidation. Possibly the alloys near 100 per cent. of antimony may consist of pure antimony.

Phosphorus.—The polished sections are copper-coloured from 0 to 3 per cent. of phosphorus, the colour getting gradually paler with increase of phosphorus. From 4 to 7 per cent. a bronze colour prevails, and from 8 to 14 per cent. a bluish-grey colour prevails. The following is a detailed description of the various alloys:—

0·08 *to* 0·25 *per cent. of phosphorus.*—In the slowly cooled samples are seen crystals of copper with more or less sharply defined boundaries, and distributed over the surface are circular spots of phosphide. These spots are also present in the quickly cooled samples.

0·4 *to* 0·6 *per cent. of phosphorus.*—The structure consists of rough dark polygonal grains, evidently consisting of impure copper. These grains are surrounded by continuous walls of a light colour, and in some places are seen lines of a greyish-blue colour running along the centre of the boundaries. The boundaries are composed of a solid solution of phosphorus in copper, from which the chemical compound Cu_3P partially separates during slow cooling. In the quickly cooled samples there is an absence of boundaries, the phosphorus compound separating in isolated globules. Fig. 22 contains 0·41 per cent. of phosphorus.

0·8 *to* 1·5 *per cent. of phosphorus.*—The phosphide is here present in larger isolated masses, and as there are no definite grains or boundaries, the phosphide must have chiefly separated and collected in the elongated patches shown in Fig. 23, with 0·8 per cent. of phosphorus.

2 *to* 3 *per cent. of phosphorus.*—The phosphide is now present in considerable quantity, in some parts forming a continuous boundary to the grains of copper, but for the most part in isolated patches. The phosphide has evidently separated from a solution, as seen by the darker portions. The phosphide Cu_3P is of a light blue colour and associated wih streaks of copper, forming a eutectic mixture in the slowly cooled samples. Fig. 24 contains 2·5 per cent. of phosphorus.

4 *to* 6 *per cent. of phosphorus.*—Definite grains of copper are present, of an elongated shape and clearly defined outline. These grains are embedded in a eutectic matrix, consisting of alternate strie of Cu_3P and copper. This eutectic increases in quantity with increase of phosphorus and the copper grains correspondingly diminish in size. Fig. 25 contains 5·8 per cent. of phosphorus.

6·5 *to* 8 *per cent. of phosphorus.*—The structure is similar to the preceding ones, but the eutectic mixture is much greater in amount and the grains of copper get very small. In the quickly cooled samples the copper forms dendrites in a light bluish-grey structureless matrix, which is a solid solution of copper and the copper compound Cu_3P, which is resolved into a eutectic mixture on slow cooling. Fig. 26 contains 7·4 per cent. of phosphorus.

8·2 *per cent. of phosphorus.*—This is the eutectic mixture, composed of alternate laminæ of copper and Cu_3P in different degrees of coarseness. Fig. 27.

9 *to* 13 *per cent. of phosphorus.*—The compound Cu_3P now crystallises out first, the crystals increasing in size with the increase of phosphorus, and become very large in the 13 per cent. alloy. Fig. 26 contains 10·7 per cent. of phosphorus.

14 *per cent. of phosphorus.*—This is the compound Cu_3P. It is extremely brittle, of a greyish-blue colour, and composed of fairly large crystals. It is very hard and can only be filed with difficulty. Under the microscope it is seen to consist of well-defined crystals of irregular shape, separated by fine boundary lines. Fig. 29.

Bismuth.—The polished sections are all copper-coloured from 0 to 55 per cent. of bismuth. At 56 per cent. the colour is paler, and at 57 per cent. the alloy has a bronze tint. This is the transition point marked, M, on the cooling curve, where mixed crystals rich in copper pass into mixed crystals rich in bismuth. From this point, up to 80 per cent., the bronze colour is maintained. From 80 to 95 per cent. the colour gets gradually paler, and at 97 per cent. is greyish-white. Beyond this the colour resembles pure bismuth. From an unaided view of the polished sections one might infer that the alloys of copper and bismuth were simply mixtures of the two metals, in which the colour of the copper predominates over that of the white bismuth. There are no purple or blue-coloured alloys like those of the copper-arsenic and copper-antimony alloys.

0·1 *to* 1 *per cent. bismuth.*—Copper with small percentages of bismuth consists of polygonal grains of copper, the cell walls of which are of a light copper colour, and in the 0·4 per cent. and upwards the cell walls contain a dividing line or lines down the centre. These lines are probably very rich in bismuth, and may account for the brittleness of these alloys, for when the metal is struck with a hammer the lines of fracture follow the same direction. If these alloys, especially those with the higher percentages, are kept for a very long time just below the freezing-point, the rich bismuth alloy segregates in irregular patches. Fig. 30 contains 0·4 per cent. of bismuth.

2 *to* 4 *per cent. of bismuth.*—In these alloys there are two constituents, one copper-red and the other of a darker colour, forming grains with gradually increasing boundaries as the bismuth increases. The structure is shown in Fig. 31, which contains 4 per cent. of bismuth.

5 *to* 10 *per cent. of bismuth.*—A complete change from the former alloy has now occurred. Large crystals of light copper-coloured solid solution are surrounded by segregated irregular patches of a light blue body, which is not uniform, but composed of a dark-coloured constituent mixed with the blue. Fig. 32 contains 10 per cent. of bismuth.

15 *to* 25 *per cent. of bismuth.*—The 15 per cent. alloy has extremely well-defined crystal grains, the interior of which has a fine eutectic structure. The boundary walls are comparatively thin and contain a light green eutectic mixture, forming irregular patches at the junction of three grains. This change to the light green from the light blue is evidently due to the decomposition or solution of the light blue body in the increased percentage of bismuth. Fig. 33 contains 25 per cent. of bismuth.

30 *to* 40 *per cent. of bismuth.*—In these alloys the green eutectic mixture has largely increased and surrounds the copper-coloured grains. Fig. 34 contains 40 per cent. of bismuth.

40 *to* 55 *per cent. of bismuth.*—In the slowly cooled alloys the constituents are the same as in the preceding, but in the quickly cooled sample there is an additional constituent of a dark bluish-grey colour, distributed over the surface in small grains, which are larger and more abundant.

in the alloys with more bismuth. As the 45 per cent. alloy contains proportions corresponding to the compound Cu_4Bi and the 52·3 per cent. alloy to the compound Cu_3Bi, the above-mentioned bluish-grey body may be a chemical compound which can only exist in the solid state by very rapid cooling, and is decomposed on slow cooling.

56 *to* 57 *per cent. of bismuth.*—In the 56 per cent. alloy the light green eutectic mixture is replaced by a light grey body, and the dark blue body (? chemical compound) only exists in minute quantity. In the 57 per cent. alloy the dark blue body is absent, even when the alloy has been suddenly cooled. The whole surface is composed of grains if two solid solutions, the light grey and the light red. They are probably dilute solutions forming a coarse eutectic mixture. Fig. 35 contains 57 per cent. of bismuth.

60 *to* 67 *per cent. of bismuth.*—These alloys are composed of two solid solutions, one light red and the other greenish-white. These are not homogeneous, but contain substances of unequal oxidisability both in the slowly and the quickly cooled samples. Dark blue grains are also present in the quickly cooled specimens and increase in amount with increase of bismuth. They may be due to the compound Cu_2Bi. Fig. 36 contains 62 per cent. of bismuth.

68·64 *per cent. of bismuth.*—This corresponds to the formula Cu_3Bi_2, but instead of being homogeneous, it is composed of about two-thirds of the above-mentioned greyish-white body and a eutectic mixture of the light red and greyish-white constituents. It was quenched in water at the freezing-point.

70 *to* 90 *per cent. bismuth.*—There are two main constituents of these alloys, consisting of a light red solid solution and the eutectic mixture, which gradually increases with increase of bismuth. Fig. 37 contains 85 per cent. of bismuth.

95 *per cent. of bismuth.*—This structure is very characteristic of an alloy bordering on a eutectic mixture. The matrix is largely eutectic and in it are dark red dendrites evidently containing much bismuth, as they are readily oxidised.

97·2 *per cent. of bismuth.*—This is a eutectic mixture, of a granular character, both constituents being very readily oxidised, even by simple polishing on a rouge pad. The structure is shown in Fig. 36.

The structure of the alloys containing 98 per cent. of bismuth and upwards resemble pure bismuth, revealing the tabular planes of cleavage characteristic of bismuth. The colour is white and the white crystals are surrounded by the above-mentioned eutectic mixture.

Lead.—A series of alloys was prepared containing from 0·1 to 99·9 per cent. of lead and treated in two different ways—one was cooled very slowly and the other quenched immediately after solidification. The following is a detailed description of the various alloys:—

0·1 *to* 0·5 *per cent. lead.*—In the slowly cooled samples the surface was composed of homogeneous copper-coloured grains, in the boundaries of which the lead appears in isolated dark blobs, mostly round, but in the form of roughly-formed triangles in some places. In the quickly cooled samples the copper ground mass is studded with fine dark markings, which, judging from the quantity present, must consist of lead with a considerable quantity of copper in solid solution. There is no eutectic structure.

1 *to* 2 *per cent. lead.*—In the slowly cooled sample the copper grains are of an elongated shape, with dark boundaries containing the lead. These boundaries become more continuous as the lead is increased, and the grains of a clearer copper colour. In the quickly cooled samples the structure is the same as in the 0·5 per cent. alloy, but the solid solution is greater in amount.

3 *to* 4 *per cent. lead.*—The grains of copper now begin to show signs of containing free lead which separates out in small black patches on their surface, but the chief portions are in the boundaries of the grains. In these boundaries occur some light blue triangular lakes. In the quickly cooled samples small grains are formed with more or less continuous boundaries.

5 *to* 9 *per cent. of lead.*—Both the slowly and the quickly cooled samples have the same structure, the latter of course being the finer. There are but few segregated patches. The grains are larger and the dark boundaries thicker than in the previous samples. Fig. 39 contains 5 per cent. of lead and has been quickly cooled.

15 *to* 25 *per cent. of lead.*—In the slowly cooled alloys are large grains of copper, from which the lead or solid solution has separated in small specks, giving it a resemblance to a eutectic mixture. These impure copper grains are surrounded by wide boundaries of apparently pure copper, and up the centre of these run disconnected dark lines of varying thickness. In some parts are segregated patches of lead, which increase in size with increase of lead. In the quickly cooled sample the whole surface shows a dendritic structure. Fig. 40 contains 15 per cent. of lead.

30 *to* 40 *per cent. of lead.*—When slowly cooled the lead segregates in large patches. There are no regular boundaries or definite structure. In the quickly cooled samples the structure is very fine, especially in the 40 per cent. alloy. Fig. 41. The surface is composed of fine striations, with some lateral ramifications, which may be confounded with a true eutectic structure.

50 *to* 70 *per cent. lead.*—In the slowly cooled alloys there is a complete absence of structure, the dark lead and the red copper patches being unequally distributed over the surface, forming a mechanical mixture. The lead patches increase in amount with increase of lead. When quickly cooled the fine striations referred to in the previous paragraph are interspersed with patches of lead. Fig. 42 contains 50 per cent. and Fig. 43 contains 60 per cent. of lead.

80 *to* 99·9 *per cent. of lead.*—The slowly and the quickly cooled alloys are the same in structure, being simply mixtures of copper and lead. Even in the 99·9 per cent. of lead, minute crystals of copper can be detected distributed over the surface of the lead, when viewed with a high power.

Effect of small quantities of arsenic, antimony, phosphorus, bismuth, and lead on copper.—It will be seen from the foregoing results that when the impurity is less than 1 per cent. the freezing-point is lowered in every case, being greatest with phosphorus and least with lead, which exhibits no tendency to form a chemical compound with copper, so that the chemical affinity between an element and copper has an influence in lowering the freezing-point in proportion to its intensity. It will be observed from the curve Fig. 1, that the fall is greatest with phosphorus, less with arsenic, and still less with antimony. Now, in the case of phosphorus, a compound is formed at 14 per cent., in arsenic at 28·3 per cent., and in antimony at 38·5 per cent., so that while the chemical compound may be formed and exist in the smallest percentages, it has the greatest influence on the alloy the lower the percentage at which the whole alloy is composed of this compound. Now, chemical compounds of metals are invariably brittle bodies, and it may be concluded that the presence of a brittle constituent in an alloy tends to diminish the malleability and make it harder in proportion to the quantity present. In accordance with this view phosphorus, as mentioned above, should, for a given percentage, be the most energetic in reducing the malleability of copper. But the reverse is the case, as will be shown by subsequent experiments.

It naturally follows from this that with the addition of equal parts of phosphorus and antimony to pure copper the former would be by far the most effective. Arsenic will exert an influence intermediate between these extremes.

It is generally recognised that bismuth is extremely injurious to copper. The foregoing experiments revealed no permanent chemical compound of bismuth and copper, and with very small portions, when the copper is slowly cooled, minute globules of bismuth separate out, and therefore break the continuity of the copper crystals. That is, the copper crystals are separated by an extremely brittle envelope, and the malleability of the whole mass is effected. Much the same remarks apply to lead, which, although not brittle in itself, is very weak and thus lowers the tenacity of the whole mass.

Phosphorus, arsenic, and antimony influence copper in virtue of their chemical action, while the action of lead

in entirely mechanical and that of bismuth may be partly chemical and partly mechanical, since in some of the alloys certain compounds are probably present in solution at certain temperatures and separate out at lower temperatures.

In order to ascertain the effect of small quantities of the above-mentioned elements on the malleability of copper, free from oxide, 0·5 per cent. of each element was added separately to pure copper and cast into a plate mould, forming ingots 2½ in. by 1 in. by ¼ in. Each ingot was carefully annealed and then rolled. No further annealing was done during the stages of rolling. Each strip was rolled, one after the other with exactly the same pinch in each case, so as to make the results strictly comparable. The following are the results:—

Phosphorus—very malleable, with quite smooth edges.

Arsenic—very malleable, with slightly serrated edges.

Antimony—malleable, with serrated edges.

Lead—imperfectly malleable and badly cracked on edges.

Bismuth—non-malleable and completely shattered.

Another series was prepared containing two elements in the copper, with 0·2 per cent. of each, making 0·4 per cent. of total impurity:—

Arsenic and antimony—very malleable, with smooth edges.

Arsenic and phosphorus—very malleable, with slightly serrated edges.

Arsenic and lead—malleable, but cracked on edges.

Arsenic and bismuth—imperfectly malleable, badly cracked on edges.

Antimony and phosphorus—malleable, but with serrated edges.

Antimony and lead—malleable, but with serrated edges.

Antimony and bismuth—moderately malleable, cracked on edges.

Phosphorus and lead—malleable, with small serrations on edges.

Phosphorus and bismuth—moderately malleable, with cracks on edges.

The above results indicate that phosphorus does not alter the malleability of copper except in so much as it makes it harder. That arsenic only slightly diminishes the malleability. That antimony makes copper less malleable than phosphorus and arsenic. That lead renders copper imperfectly malleable and bismuth makes it quite unworkable.

Arsenic and antimony together are as good as arsenic alone, and better than antimony alone. Arsenic or antimony added to copper containing bismuth diminishes the brittleness caused by the bismuth alone. Arsenic or antimony added to copper containing lead diminishes the brittleness caused by lead alone. Phosphorus improves the malleability of copper containing antimony, bismuth, or lead.

The above effects refer to the action of elements upon pure copper, but commercial copper contains cuprous oxide and the first action of the element would be to deoxidise this compound and form oxide of the added element, so that only that portion of the element which is in excess of that required for the deoxidation can act directly on the copper to form a copper compound.

Assuming that the higher oxides are formed in removing oxygen from copper by the addition of phosphorus, arsenic, or antimony, namely, P_2O_5, As_2O_5, Sb_2O_5, then 62 of phosphorus, 160 of arsenic, and 244 of antimony would be required respectively in combining with the same quantity of oxygen, or a ratio of 1:2.4:4; that is, 1 part of phosphorus would effect the same result as 4 parts of antimony.

Discussion.

The Chairman congratulated Mr. Hiorns upon his exhaustive paper, the final conclusions of which must be of the greatest importance to those who were working with these alloys.

Prof. T. Turner said, when seeing the photo-micrographs on the screen he had felt sorry that colour-photography was not available, because in the copper alloys colour played such an important part. He had had an opportunity of seeing a number of the copper-arsenic specimens prepared by Mr. Hiorns, and the colours of the blue and purple constituents were extremely brilliant, so that a very inadequate conception of what the alloys are really like was obtained from the ordinary photographs. Shepherd, of America, had criticised the results obtained by Mr. Hiorns, and some of the points were still in doubt. Of course, arsenic in copper alloys was difficult to deal with, because arsenic was volatile and no doubt there might be different compositions in different parts of the alloys. The antimony copper curve of Mr. Hiorns agreed nearly with that given by Charpy in the well-known report "Sur les Alliages." The shape of the bismuth and lead curves were, of course, very different from the other three given, and they corresponded with the facts, which were already well-known, particularly in the case of lead, that copper and lead tend to separate on cooling, and that there is a different constitution altogether in these cases.

Mr. A. E. Tucker said that he should have wished that Mr. Hiorns had included the element iron in his subject, because the effect of iron on copper was very important. A few years ago the presence of arsenic in copper was regarded as exceedingly inimical to its properties, but arsenic up to a quarter and even up to 0·4 per cent. was now stipulated for in the specification for Admiralty and locomotive tubes owing to its reducing properties. Similarly the beneficial effects of phosphorus were to be attributed to its reducing action. Some brass-founders in Birmingham had so recognised the importance of phosphorus to the manufacture of ordinary brass castings, that they purposely used copper containing some 10 to 14 per cent. in their commonest castings, since it so increased the strength and general mechanical properties of their castings, that they could reduce their sections, and, further, the amount of wasters was so lessened by the addition that, although an expensive material, its use was economical. He agreed with Mr. Hiorns in fixing the possible percentage of phosphorus in copper somewhere about 14 or 14½ per cent. He was aware that German phosphor copper of 15 per cent. was being advertised for the London market, but he had occasion recently to analyse and determine the phosphorus in such samples, and he had found that although the phosphorus itself sometimes reached 15 per cent., it existed, curiously enough, partly in the form of red phosphorus and exterior to the true alloy, and by slightly warming it one could actually smell the phosphorus in such assumed alloy.

Mr. W. Rosenhain considered that a good many of the statements made by Mr. Hiorns were a little risky; the data he had given did not seem adequate to establish the results based upon them. The author had only given the actual freezing-point curves, and those only for alloys at rest, or at all events in the absence of inoculation which would prevent errors arising from surfusion. Thus considerable errors might creep into the freezing-point determinations. He (Mr. Rosenhain) was led to make this remark by Mr. Hiorns' statement that one of his results appeared to be at variance with the phase rule. The summit of the curve in question seemed to him to be far too flat to justify such a statement. Had Mr. Hiorns given more complete thermal data, he might have much further confirmation as to the various compounds, solid solutions, and eutectics occurring in these alloys. While Heycock and Neville had practically been the first to give a complete investigation of a system of binary alloys, the methods had been adopted, and to some extent advanced, by Tammann. The additional data required by these more complete methods were the temperature range and time occupied by the initial solidification and the temperature and duration of the eutectic arrest. The temperature interval between the beginning and end of the initial crystallisation served as a criterion of the presence of solid solutions, since in all these the interval in question was large as compared with that in a pure substance. Further, the duration of the eutectic arrest point for a given mass of alloy was a maximum for alloys at or near the composition of the eutectic in question, while it fell to zero for alloys of the composition of a pure compound. Mr. Hiorns had further made two statements which it was difficult to

accept. One of these referred to a copper-arsenic alloy which, while said to be a chemical compound, was described as having a heterogeneous structure. Discrepancies of this sort between the results of microscopic examination and the indications of the freezing-point curve had often been observed by metallurgists, but it had always been found that the micro-structure was the truer guide; when a heterogeneous structure was found where a simple body was expected, a chemical change in the alloy at a temperature below the freezing-point had often been detected. The other statement was that a solid solution of copper and a copper-phosphorus compound crystallised out as such and resolved itself into the eutectic on slow cooling. Now, as a matter of definition, the solid phase or phases crystallising at a minimum point were the eutectic, whatever their structure, but if Mr. Hiorns had discovered a eutectic having a homogeneous structure like that of a solid solution when rapidly cooled and resolving itself into the usual banded structure on slow cooling, it was a remarkable fact which should be strongly emphasised. The statement as it stood, that a solid solution crystallised at the lowest point of a freezing-point curve, and became transformed into a eutectic on slow cooling, could hardly be accepted.

Dr. T. S. PRICE said he was much struck by the apparent regularities for the three curves, copper-phosphorus, copper-arsenic, and copper-antimony. According to the curves, the first compounds formed as the percentage of element added to the copper increases are respectively Cu_3P, Cu_3As, and Cu_3Sb. The lowering of the freezing-point of the copper was due to the presence of the compounds, as far as the first portions of the curves were concerned, and if the depressions observed in any one curve were taken, it ought to be possible to calculate those for the other curves, since the depression depended on the number of molecules of the dissolved substance.

The observations made on the copper-antimony alloys were probably the most correct; they were consequently taken as the basis of calculation. Bismuth was also included in the calculation, assuming that the compound Cu_3Bi was formed. The formula used in the calculation was readily obtained, and was

$$\frac{3100}{P} - 221.5 = \frac{7500}{As} - 265.5 =$$

$$\frac{12000}{Sb} - 310{\cdot}5 = \frac{20850}{Bi} - 399$$

where P, As, Sb, Bi were respectively the percentages of the corresponding elements for any definite lowering of the freezing-point.

The agreement between calculation and experiment, considering that the freezing-point laws are only valid for dilute solutions, was very good in the case of phosphorus, but not so good, although satisfactory, in the case of arsenic; with bismuth there was no agreement.

The conclusion therefore seemed justified, that the lowering of the freezing-point of the copper in the first three cases was due to the compounds Cu_3P, Cu_3As, and Cu_3Sb, and this agreed with the freezing-point curves. The case of the alloys of copper and bismuth was interesting, since it was somewhat difficult to draw definite conclusions from the freezing-point curves or from the micro-photographs. The break in the curve at 57 per cent. Bi might be due either to the separation out of the new solid phase Cu_3Bi (52·3 per cent. Bi), which would then be capable of existence only in the presence of an excess of bismuth, or it might be caused by the formation of two conjugate solutions (as in the copper-lead alloys), one of bismuth in copper, and the other of copper in bismuth. In the former case the curve, assuming that no other compound between copper and bismuth was formed, would be continuous down to the eutectic point, 97·2 per cent. Bi; in the latter case the curve would remain horizontal as long as the two conjugate solutions existed, and then it would show a break and fall continuously to the eutectic point. An examination of the curve would show that no definite conclusion with respect to these points could be arrived at, nor did the micro-photographs help in the matter, since they were in all probability complicated by changes which had taken place in the solid on cooling. The above calculation, however, would point to the non-formation of the compound Cu_3Bi, so that the bismuth probably dissolved in the copper without uniting with it.

If this were so, it would be easy to calculate whether the bismuth was present as single or double molecules. The following table gives the calculated percentages of bismuth necessary to produce a given lowering of the freezing-point, assuming that bismuth is (*a*) monatomic, (*b*) diatomic, in solution. The copper-antimony alloys were again taken as the basis of the calculation:—

Lowering of the freezing point.	Found.	Per cent. Bi Calc. for Bi.	Calc. for Bi_2.
55°	11·5	9·1	16·6
105°	28·5	16·5	28·4
175°	52·0	29·8	46·0

The figures were in favour of the association of bismuth when dissolved in copper, agreeing with what Ramsay found for the solution of bismuth in mercury and with what Heycock and Neville found for the solution of bismuth in tin. Much valuable information with respect to the interpretation of Mr. Hiorns' results in the light of the phase rule, and of the micro-photographs, would have been obtained if the complete cooling curves of the various alloys had been observed, and not simply the freezing points. Baykoff's curves for the copper-antimony alloys were readily interpreted by the phase rule, but Mr. Hiorns had never been able to obtain curves which agree with those of Baykoff.

Mr. F. H. ALCOCK said that the close analogy between the formulæ and figures relating to the various elements and their place in the periodic system had struck him. Some figures were given for phosphorus, arsenic, and antimony, *viz.*, 14 per cent., 28 per cent., and 38 per cent. respectively, and these bore a strong relation to the atomic weights, while the same remark applied to the formulæ. That lead did not come within the same category could be thus explained, because its place in the periodic table was very different from that of the other three elements.

Mr. E. LEWIS said that in the last part of his paper, Mr. Hiorns seemed to overlook the point that in practice there were two distinct methods of making copper: there was the copper cast direct from the refinery furnace, and that which was cast from the crucible. If phosphorus was added in the refining furnace in order to get a good casting, the copper would be absolutely spoilt, but in crucible furnaces if the copper were of good quality phosphorus might be added. But one could not cast good copper tubes from crucibles with ordinary copper such as Mr. Hiorns seemed to suggest. Then, with regard to the statement that metals like lead existed as oxide in commercial copper, lead oxide was a very fusible and brittle substance, and if lead were present as oxide it was rather improbable that copper containing it would be a tough metal. It seemed more probable that the lead present in commercial copper existed as metallic lead dissolved in the copper oxide eutectic, the same as lead was dissolved in the copper-arsenic eutectic in arsenical copper.

Mr. HIORNS, in reply, said he felt extremely grateful to Mr. Rosenhain for pointing out some of the probable errors in the paper, or rather in the manner in which certain points were interpreted. He also thanked Dr. Price for showing by calculation how the experimental work agreed in some of the cases with the calculations. With regard to Mr. Lewis's remarks, he only claimed for his experiments the properties obtained under the conditions of the experiments, that was, with perfectly pure copper, and he purposely did not go into the question of the exact manner in which elements occurred in commercial copper. He had only stated the view as to impurities assumed to exist as oxides, but from what he had brought forward and from the examination of these curves it would be seen that it was probable that some

of these compounds did not exist as oxides but in some other form. The readiness with which phosphorus combined with copper was apparent, and the question was whether the compound was decomposed in the presence of small quantities of oxygen.

London Section.

Meeting held at Burlington House, on Monday, June 11th, 1906.

MR. A. G. SALOMON IN THE CHAIR.

PURIFYING AND STABILISING GUNCOTTON.

BY R. ROBERTSON, M.A., D.SC.

In the manufacture of guncotton the material, after nitration, is purified and rendered stable by a process commonly referred to as the boiling of guncotton. This process has been the subject of a considerable amount of experimental work at the Royal Gunpowder Factory, in the course of which trial has been made of many different schemes of boiling. The description of some of these and of the method adopted as a result of the trials forms the subject of the present paper, which is contributed by permission of the Superintendent.

It is the object of such a process to secure a guncotton of the greatest possible chemical stability in the minimum of time and with the least decomposition of the substance.

When dealing with the question of the stability of guncotton, experience has conclusively shown that results of small scale experiments, whether with laboratory apparatus or with small wooden vessels, arranged to simulate the conditions obtaining in the large boiling vats, are altogether misleading and useless; the conclusions arrived at in the present instance will, therefore, be founded on results obtained on the large scale, when quantities of 1,000 kilos. of guncotton are boiled in large vats with 10,000 kilos. of water or other solution.

In these experiments, the cotton was nitrated by the displacement process, and was treated with cold water till apparently neutral, before transferring to the boiling vats.

The objects of the next operation—boiling of the guncotton—are to free the material from certain impurities, such as traces of free acids, unstable products of the nitration of the cellulose, among which are mixed cellulose nitro-sulphuric esters, possibly cellulose nitrous esters and unstable bodies arising from the action of the nitrating acids, both on the cotton cellulose itself, and on the less resistant celluloses which inevitably occur as traces of seed husk, etc., in the cotton used for the manufacture.

Of these impurities the possibility of the presence of nitro-sulphuric esters in nitration products of cellulose was recognised by Cross and Bevan (Ber. 34,2496 [1901] and later, Ber. 38, pp. 1859 and 3531 [1905]), and to the presence of these mixed esters the instability of some nitro-celluloses was ascribed by C. Napier Hake and R. J. Lewis (Journal of Society of Chemical Industry, 24, 374 [1905]). Lunge and Bebie (Zeits. fur angew. Chemie 22, p. 539 [1901]) considered the possibility of the formation of cellulose nitrous esters, and made experiments on the stability of guncotton prepared from acid mixtures, both free from and with the addition of nitric peroxide, and Berthelot (Comptes Rendus, 17th Sept., 1900) has also suggested the formation of nitrous esters. Of other impure products of nitration of cellulose, nitrated sugars of small stability are indicated by the work of Will and Lenze (Ber. 31, p. 68 [1898]), and the solubility of products of liqueous character in nitrating acids, and instability of the nitrate formed, are dealt with in "Cellulose," p. 132 and, in "Researches on Cellulose," p. 131, by Cross and Bevan.

For many years guncotton at Waltham Abbey has been purified by boiling with water in large vats, the water being raised to the boiling point by steam introduced and distributed below the false bottom of the vat. At the finish of one boiling, the water is run off, and replaced by fresh water, which is again raised to the boiling point by steam, the actual time of ebullition being taken as the duration of the particular boiling.

Investigations as to the best method of purification have been made in two main directions. In the first place, the effects of variations in the relative duration of the different boilings with water were studied, and, secondly, experiments were made with various alkaline treatments. The investigation involved a large amount of analytical and experimental work, as for each of the boilings, of which there would be from seven to sixteen in one experiment, (*a*) the wash waters were examined for free acid or alkali, sulphates, nitrates, and nitrites, and (*b*) the corresponding guncotton was examined for nitrogen-content, insolubility in ether-alcohol, solubility in acetone, percentage of sulphate present, mineral matter, and tested for purification and stability by the Abel, Will, Bergmann, and Junk, fume and other tests. From the results of this examination of the wash waters and of the progress of the guncotton in stability with each successive boiling, deductions were then drawn as to the relative merits of the different methods of boiling.

I. *Boiling with water alone.*—The newly nitrated guncotton, after it has received a washing with cold water, although apparently neutral to litmus (unless pressure be applied) in reality contains a considerable quantity of the nitric and sulphuric acids of the nitrating mixture still adhering to the fibre, amounting to about 1 per cent. of acid (as H_2SO_4) calculated on the guncotton. As will appear later, this acid is found to play an important part in the economy of the process, so that if there were a thorough elimination of nitrating acid by the cold water washing, an addition of acid to the initial boilings would be advisable. The water used for boiling was ballast-filtered water containing lime as carbonate to the extent of 20 parts per 100,000, and sulphuric acid in the form of calcium sulphate to the extent of 6 parts H_2SO_4 per 100,000.

Experiments were made to determine which of the two processes was to be preferred, namely, (A) a scheme of boiling characterised by long boilings at the beginning with shorter boilings at the end, and (B) one with short boilings at the beginning and long boilings later. The former of these treatments was found to be in every way the better, as the following comparison will show.

	Treatment A. Long followed by short boilings.	Treatment B. Short followed by long boilings.
Wash Waters:		
Elimination of free acid	First and second boilings acid.	First to third or fourth boilings acid.
Alkalinity	Soon reaches a constant.	Towards end decreases from a maximum.
Nitrite	Rises to a maximum, then decreases.	Steadily increases.
Sulphate	Reaches minimum earlier than in B.	
Guncotton:		
Nitrogen	Practically the same as B.	
Solubility in ether-alcohol	Tendency to be lower than with B.	
Free acid in G/C of early boilings	Small in quantity after first boilings.	Not reduced to same extent till after third.
Sulphuric acid organically combined	Noticeable only after first boiling and small in quantity.	In much greater quantity in early boilings persisting till the third or fourth.
Abel heat test at 76·4° C.	Over 10′ at third boiling.	Over 10′ at sixth boiling.
Paste (G/C+N/G) heat test at 76·4° C.	Over 10′ at fourth boiling.	Over 10′ at seventh boiling.
Stability tests (Will. Bergmann and Junk, fume and other tests)	Stability is attained at an earlier stage than with treatment B.	

From this comparison it is evident that the longer boilings at the beginning (two periods of 12 hours in this case) are superior to short initial boilings (of 4 or 2 hours for example). Examination of the results of analyses of the wash waters brings out the advantage of the more prolonged initial acid treatment in hydrolysing impurities, as is shown by the earlier attainment of the normal minimum of sulphate in the water, and also points to the disadvantage of prolonged later boilings (two periods of 12 hours in this case) as tending to decompose the guncotton, for under these conditions the nitrites in the wash waters are found to increase with simultaneous disappearance of the alkalinity of the water. If the later boilings be prolonged, the nitrous acid produced either by the intrinsic decomposition of the guncotton at this temperature, or by the hydrolysis of the nitric ester by the calcium carbonate in solution, may neutralise the latter so that the guncotton is being treated in a neutral or even slightly acid solution.

Turning next to the guncotton itself, the importance of a thorough boiling in the solution of dilute acid which proceeds from the traces of nitrating acids retained by the guncotton is again apparent. Thus, by this treatment, the sulphate organically combined with the guncotton has practically disappeared after boiling for 12 hours, whereas with the shorter initial boilings its gradual elimination by hydrolysis can be followed step by step. Experiments with the Will and other tests have shown that guncotton containing this sulphuric ester is in a highly unstable condition; its early removal is, therefore, a matter of importance. The guncotton was also examined after each boiling as to its progress in purification and stability by the numerous tests mentioned in the Table, and it was found that the scheme in which long boilings in dilute acid were followed by gradually shorter neutral or faintly alkaline boilings, was superior to that in which short initial boilings were succeeded by long final ones, inasmuch as not only by the "trace" tests but also by those tests which involved a wider decomposition of the guncotton such as the tests of Will, Bergmann and Junk, etc., purification and stability of the material were obtained more readily and earlier by the former treatment than by the latter.

II. *Alkaline Treatments.*—Practically speaking, the alkalis that would be chosen for trials in connection with the boiling process, are sodium and calcium hydrate, of the caustic alkalis, and sodium and calcium carbonate of the carbonated alkalis.

Effect of boiling in caustic liquors.—In an experimental boiling in which lime water was employed, this solution was used in the vat for displacing the water present in the guncotton. After this the guncotton was given four 3-hour boilings with saturated lime water, boiling being thereafter continued with the ordinary water.

A well-marked feature in this experiment was the tendency of the wash waters to develope free sulphuric acid after having been alkaline. The following table shows the nature of the change.

The first change towards acidity (at the 7th boiling) occurred in the usual course of boiling, but the second (at the 13th boiling) after the vat had been standing for a week. The sulphuric acid thus developed and found in the vat water is doubtless derived from the decomposition of sulphuric acid organically combined with the guncotton. Besides this, the method of boiling in question was found to have many other disadvantages. Although the strength of even a saturated solution of Ca (OH_2) is small (0.16 per cent.), the hydrolysis of the nitric ester was considerable. This was shown by the abnormal proportion of nitrites found in the earlier boilings when caustic lime solution was used, for example 0·04 per cent. as HNO_2 in the 4th, and by the rise in solubility in ether-alcohol of the guncotton. The greater activity of hydroxyl over hydrogen ions in the saponification of esters has been shown by Wijs (Zeit. für Phys. Ch. 12, 514 [1893]) to be in the ratio of 1,400 to 1, and is no doubt the cause of this breaking down of the nitric ester as well as of the fact that the guncotton underwent a physical change, losing its strength of fibre, and becoming short and friable.

As regards stability, the guncotton treated in this way gave distinctly poor results, when tested by Abel, Will, and other tests.

These objections—the somewhat drastic hydrolysis of the ester with rise in solubility in ether-alcohol and breaking down of the fibrous structure of the guncotton having been confirmed on a smaller scale with dilute caustic potash solution, it was not thought to be necessary to proceed farther on the large scale in the direction of boiling with other caustic alkaline solutions.

Effect of boiling with alkaline carbonates.—A process for boiling guncotton which was employed by a private company in this country until within the last few years, consisted in boiling the pulped guncotton with chalk in iron vessels, but the results obtained as regards the stability of the product—which was submitted to the Superintendent of the R.G.P.F. for examination—were so poor that the process of boiling was abandoned by the company.

Indications as to the effect of boiling in presence of $CaCO_3$, and of its failure to effect stability without an initial acid treatment, have been frequently observed. Thus, in the experiment with caustic lime solution, a considerable quantity of $CaCO_3$ was formed by the action of the CO_2 present in the steam on the $Ca(OH_2)$ and the succeeding boilings may be considered as being examples of boiling in presence of excess of $CaCO_3$. The result was nevertheless unsatisfactory, as was shown. Again, it has not been found that any marked improvement in stability has resulted from continued boiling of guncotton with the usual water which contains a small quantity of $CaCO_3$.

With sodium carbonate solution, an experimental boiling has been made. The scheme of boiling consisted in two 4-hour boilings with Na_2CO_3 solution of 0·5 per-

Guncotton in vat heated with $Ca(OH)_2$ solution to displace water and boiled 3 hours with 4 changes of this solution; then boiled with ordinary water.

cent. strength, followed by eight 4-hour boilings and three 2-hour boilings, all of 0·2 per cent. strength.

Examination of the wash waters showed that the alkali originally present to the extent just mentioned had almost disappeared by the end of each boiling, while the proportion of nitrite (as HNO_2) was 0.05 per cent. or about ten times the quantity found in the later boilings with water.

Examination of the guncotton showed that the solubility in ether-alcohol had risen to a high figure (17·1 per cent. as against 5.4 per cent. in a control experiment with the usual boiling) and that the guncotton, even after ten boilings, still contained more than three times the quantity of sulphate that is found under the usual conditions. The quantity of Na_2CO_3 which disappeared was about 6 kilos. per hour. It was also observed that the guncotton fibre became disintegrated at an early stage, to a less extent than with calcium hydrate, but still to a much greater extent than in the usual process.

It is therefore evident that the hydrolysis of the nitric ester in the dilute solution of Na_2CO_3 employed, is of too drastic a nature and produces finally an unsatisfactory guncotton.

This investigation has afforded the following information on the boiling of guncotton. The experimental boilings have shown that for the elimination of impurities from the guncotton and the rapid attainment of a stable product, boiling in dilute acid at the beginning of the process is superior to an alkaline treatment. This acid boiling should not be unduly curtailed, or elimination of impurities will be rendered difficult. In the present instance, an initial 12 hours' acid boiling has been found efficacious. The quantity of acid left in the guncotton from the nitrating process, will depend on the nature of its treatment after nitration, and on the alkalinity of the water. It is important to avoid pushing this elimination too far, as actual experiments have shown that deficit of acid in the first boiling retards the purifying and stabilising process. It would not be possible to give a figure applicable to all cases, but it may be mentioned that good results have been obtained when the first wash water is found to contain acids equal to 1 per cent. (as H_2SO_4) calculated on the guncotton present.

If, in the process of manufacture, the quantity of acid in the first boiling were found to be too small, the addition of a small quantity of acid would be advisable.

As showing the degree of elimination of one of the impurities—the cellulose nitro-sulphuric ester—the percentages of total sulphate in three guncottons, manufactured at the time of writing, may be quoted. These are 0·09, 0·07, 0·05, 0·07 per cent., and fall much below the proportions found by Hake and Lewis (*loc. cit.*, p. 377) even after removal by them of sulphates soluble in water and dilute acids.

After the acid period has passed and the guncotton is being boiled in water faintly alkaline from the presence of dissolved calcium carbonate, it is inadvisable to prolong this process unduly as no improvement in stability is produced, and the guncotton is slightly decomposed.

The alkaline treatments which were investigated did not prove so efficacious as the initial acid boiling in removing impurities, and had the additional disadvantage of producing a considerable hydrolysis of the nitric ester itself.

As a result of these experiments, the present method of boiling was adopted at the R.G.P.F., namely, 12+12+4+4+4+4+4+2+2+2 hours, with a cold water washing between the first and second, and second and third boilings.

Discussion.

Col. Nathan said it was not perhaps his place to criticise a paper which had originated in his laboratory, but he might add a word or two of explanation as to its origin. When the manufacture of guncotton was started at Waltham Abbey by what was now called the displacement process, it was evident that the guncotton, as it went to the boiling vats, was capable of being stabilised with less boiling than guncotton made by the old Abel process, and they came to the conclusion that it was time to thoroughly investigate the chemistry of the purifying process. Dr. Robertson went to work, not in the laboratory, but on the manufacturing scale. They used the ordinary guncotton vats of 1,000 kilos. capacity, and submitted the guncotton to various treatments in their vats, and this paper had given the results obtained. One practical result had been to reduce the time of boiling from 72 to 50 hours, which of course meant a considerable economy in steam. He did not say the same results would follow the adoption of that system in other factories, because purification no doubt depended to a great extent on the character of the water which was used, but he fancied that, as they had made such a big reduction in the time of boiling it would be possible for other factories to do the same if they adopted the process, which he thought was a chemically sound one. Being desirous at all times of assisting the trade, he came to the conclusion that the results of these experiments should be made known, and there was no better way of doing it than to arrange for Dr. Robertson to read a paper before the Society of Chemical Industry, and the sanction of the War Office to his doing so had therefore been obtained. He hoped it might be of use to the trade, and trusted that from time to time they would be able to give information on other points which might come to light in the course of their investigations.

Prof. W. R. Hodgkinson said he gathered that the author had been using a little acid to help in the hydrolysis of what he considered the most serious matter in connection with guncotton, sulphates of cellulose, which undoubtedly remained in and were the cause of slow or rapid decomposition. A slight amount of acid in the earlier hot washing was more active in hydrolysing some of these sulphates than water alone.

Mr. W. F. Reid said that in 1881-2 he had carried out numerous experiments on this subject, but the endeavour to get the material alkaline in the first stage had probably been the cause of failure. Was the separation of the water from these numerous boilings carried out simply by draining off, or were other steps taken to diminish the quantity of residual water, because it became a matter of importance when the water available was not pure?

Mr. J. F. Briggs stated that together with Messrs. Cross and Bevan (this J., 1905, 685, 1251) he had investigated this matter in another aspect in connection with the aceto-sulphates of cellulose. They found that even under the action of cold distilled water and still more of boiling water, the sulphuric acid residue of these mixed esters was gradually split off, whereas on treatment with alkaline solutions the whole of the acetic acid residue could be eliminated by saponification whilst the combination between the cellulose and the sulphuric acid remained intact in the form of a cellulose sulphate. This behaviour was explained by the fact that the sulphuric acid residue in these esters exists in the form of $-SO_4H$, which is readily hydrolysed by the action of water or acids, but which becomes $-SO_4M'$ in presence of alkalis, towards which it is remarkably stable. Further, by treating guncotton with the sulphating reagent they had succeeded in combining quantities up to 10 per cent. of sulphuric acid with the cellulose, displacing a corresponding quantity of the nitric acid. Thus they had been able to study the properties of the mixed sulphuric esters of cellulose in the gross, rather than in the minute proportions in which they occur in guncotton.

Dr. Robertson in reply said it was not possible to go into the matter of the organically combined sulphuric acid, but when the paper was published it would be seen that organic sulphate was undoubtedly present in some products of nitration, and about the instability of guncotton containing this organic sulphate there was no doubt whatever. Experimental products had been obtained which, although they gave a good Abel test, were proved by storage trials and other tests to be quite unstable, and in these the organic sulphate was present in considerable quantity. The method of reducing it to an almost vanishing point on the large scale was the method of acid hydrolysis at the start. In reply to Mr. Reid, the water was strained off from the vats.

ELECTRO-CHEMICAL PROBLEM OF THE FIXATION OF NITROGEN.

DR. RUSSELL W. MOORE IN THE CHAIR.

ANALYSES OF JALAP.

BY RUSSELL W. MOORE, M.A., M.SC.

At the reading of a paper by me on this subject before the Section on March 25th, 1904 (this J., 1904, 412) in which the average resin content of ninety-eight samples of jalap was given as 12·60 per cent., some discussion arose as to whether this was not an excessive average for the jalap to be found in the market. One member of great experience, in dealing with crude drugs, gave it as his opinion that jalap testing as high as 12·60 per cent. of resin was not easily obtainable, and that the ordinary jalap of commerce averaged from four to seven per cent. of resin. Since the former paper was written I have had occasion to test a much larger number of jalap samples, the results of which are here given, the different lots being separated by lines:—

1	4·82*	58	4·70	116	4·75	172	7·00	230	5·14

* No. 1 was an average of ten samples.

Of the 276 samples examined, only fifteen were equal to or above the standard of 11 per cent. of resin prescribed by the Treasury regulations. This result and the average content of 5·95 per cent. of resin go to confirm the statement that low-grade jalap is of frequent occurrence, and show the extremely variable character of the drug as imported into this country. An inspection of the results obtained in packages of the same lot also show that they vary greatly.

ADDITIONAL ANALYSES OF ASSAFŒTIDA.

BY RUSSELL W. MOORE, M.A., M.SC.

The analyses here given are for the purpose of comparison with those previously published in this Journal. The method of analysis followed was identical with that described (this J., 1899, 987). The samples represent many lots imported at ports other than New York, the separate lots being indicated by lines. The following results were obtained:—

No.	Per cent. Resin.	No.	Per cent. Resin.	No.	Per cent. Resin.	No.	Per cent. Resin.	No.	Per cent. Resin.

		58	50·00	82	24·00	117	13·20	Average	
33	43·00	59	63·20			118	31·50	31·45	
34	48·25	60	58·00	83	16·50	119	15·10		

These results have been tabulated for the purpose of comparison with previously published results.

The figures in Table A, show only a total of 15·49 per cent. of the samples examined to contain the 50 per cent. of resin required by the Treasury regulations, and indicate the necessity of frequent chemical examinations of the importations of this drug. Much of the inferior drug met with is fictitious in character, consisting of impure gypsum cemented together with assafœtida resin. Other samples were of an inferior quality, plainly due to crude and imperfect methods of collecting the drug. Several samples of assafœtida resin were also tested, with the following results:—

Resin from Assafœtida.

No.	Resin.	No.	Resin.
1	....91·87 per cent.	3	....91·67 per cent.
2	....92·60 per cent.	4	....94·89 per cent.

Meeting held at the University, Leeds, on June 18th, 1906.

PROF. A. G. GREEN IN THE CHAIR.

THE DIRECT ESTIMATION OF NITROGLYCERINE IN CORDITE, &c.

BY OSWALD SILBERRAD, PH.D., HENRY ARLETT PHILLIPS, AND HENRY JOHN MERRIMAN.

No method has hitherto been devised for the direct estimation of nitroglycerine in cordites and allied explosives. It is customary to extract the nitroglycerine and mineral jelly with ether, and to weigh the residual nitrocellulose. Methyl alcohol is used to separate the nitroglycerine and mineral jelly, the latter being weighed and the former determined by difference. The disadvantages of having no direct method for the estimation of such an important constituent of cordite as nitroglycerine are manifest.

Firstly, the methods for the determination of mineral jelly are somewhat unsatisfactory. Thus, on keeping a powder, a certain portion of the mineral jelly becomes soluble in methyl alcohol, and is therefore estimated as nitroglycerine; and secondly, it not infrequently occurs that the powder contains some additional ingredient, the presence of which precludes the estimation of nitroglycerine by difference.

The chief difficulties met with, in attempting to estimate nitroglycerine in cordite directly, are due to the unavoidable presence of a volatile solvent used for its separation. Such solvents interfere with the reactions of nitroglycerine to such an extent that all previous attempts to devise quantitative methods have been fruitless.

The present method is based on the reduction of the saponification products of nitroglycerine to ammonia, and will be found to be satisfactory and accurate.

Saponification alone does not give quantitative results. In this connection Hay's work (Monit. Scient. [3] 15, 424) should be referred to. According to this author the saponification may be represented by the following equation:—

$$C_3H_5(ONO_2)_3 + 5KOH = KNO_3 + 2KNO_2 + CH_3COOK + HCOOK.$$

The present work has shown, however, that this reaction is not quantitative, ammonia and other products always being simultaneously formed.

EXPERIMENTAL.

Direct evaporation of ethereal solution of nitroglycerine.—A series of experiments in this direction showed:—

(*a*) That ether cannot be removed from nitroglycerine without loss of the latter.

(*b*) That the loss is reduced to a minimum when the removal of the ether is carried out at a low temperature in a current of air.

(*c*) That even under the most carefully controlled conditions constant results cannot be obtained.

As an example, the following experiment may be cited:—

Weighed quantities of nitroglycerine were dissolved in ether, the ether evaporated in a current of air, and the nitrogen estimated by Lunge's method in the residue.

0·4508 grms. of nitroglycerine originally taken gave 140·8 c.c. of nitric oxide at 758·9 mm. and 19° C. = 18·24 per cent. N.

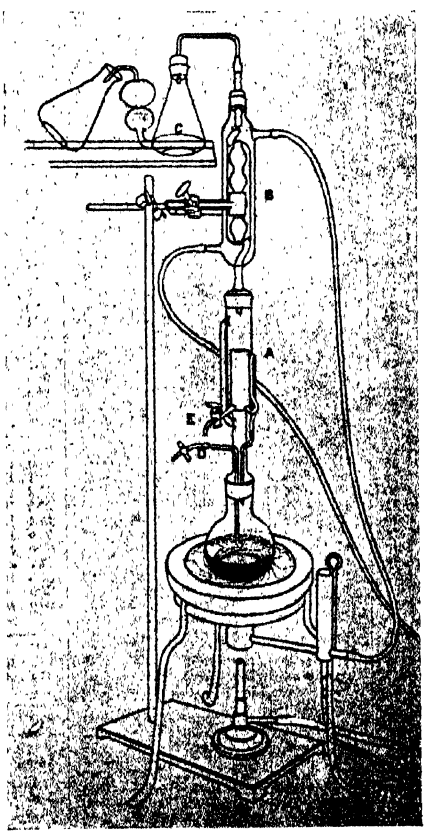

FIG. 1.

0·4501 grms. of nitroglycerine originally taken gave 140·5 c.c. of nitric oxide at 762·2 mm. and 22·8° C. = 18·07 per cent. N.

This corresponds to 98·58 and 97·69 per cent. of nitroglycerine respectively. Experiments were therefore carried out with a view to devising a direct method for estimating nitroglycerine in an ethereal solution. The results which ultimately led to the development of a satisfactory method are briefly summarised in the following table:—

From the above results it will be seen that it is possible to overcome the difficulties attending the direct estimation of nitroglycerine in ethereal solution (as obtained in the analysis of cordite) by reducing the saponification produots with zinc, iron, and caustic soda; under these conditions the nitrogen is quantitatively converted into ammonia.

The apparatus* used is depicted in the accompanying

* To be obtained of Messrs. Townson and Mercer (34, Camomile Street), or Messrs. Muller and Co. (6, Orange Street, Red Lion Square).

Experiments on the quantitative estimation of nitroglycerine in ethereal solution.

Conditions of experiment.	Percentage, of the nitro glycerine taken, found by experiment.	Molecular proportion of reagent per molecule of nitroglycerine taken.	Remarks.
I. Saponification by boiling the ethereal solution with alcoholic caustic soda:			
Experiment 1 product titrated unfiltered	86·35*	4·32 NaOH	The reaction was hardly complete after 24 hours boiling.†
„ 2 „ „ „	86·48*	4·32 NaOH	
„ 3 „ filtered	88·46*	4·42 NaOH	
„ 4 „ „ „	89·10*	4·45 NaOH	Ammonia was evolved and in three cases estimated:
II. Saponification by boiling the ethereal solution with alcoholic caustic potash for 28 hours:			(1) 1·39 per cent. of the total nitrogen present was evolved as ammonia.
Experiment 1 product titrated unfiltered	84·65*	4·23 KOH	(2) 1·65 per cent. „ „ „
„ 2 „ „ „	85·10*	4·25 KOH	(3) 2·09 per cent. „ „ „
III. Saponification by heating the ethereal solution with alcoholic caustic potash in a sealed tube:			
Experiment 1 for 6 hours at 100° C...	81·75*	4·09 KOH	
IV. Saponification by warming the ethereal solution with sodium ethylate:			The reaction proceeds much more readily than in the above cases, being fully completed in 6 hours. Ammonia was invariably evolved and estimated in two cases:
Experiment 1	86·16*	4·31 C_2H_5ONa	(1) 1·5 per cent. of the total nitrogen present was evolved as ammonia.
„ 2	86·53*	4·33 C_2H_5ONa	(2) 0·61 per cent. „ „ „
V. Saponified by heating the ethereal solution with alcoholic ammonia in a sealed tube:			The reaction is obviously incomplete, as at least 3 molecules of ammonia must be required.
Experiment 1 for 6 hours to 100° C...	—	1·88 NH_3	
VI. Reduction of ethereal solution to ammonia by means of a copper zinc couple:			Traces of unchanged nitroglycerine could still be detected in the flask after prolonged boiling.
Experiment 1 in alkaline solution	69·51	—	
„ 2 in acid solution	54·20	—	
VII. Reduction of ethereal solution to ammonia with zinc dust and sulphuric acid in presence of salicylic acid:			Reaction was very violent and altogether unsuited for quantitative work. Results are therefore not included.
Experiment 1	—	—	
„ 2	—	—	
VIII. Reduction to ammonia by boiling ethereal solution with tin and hydrochloric acid.			Reduction was carried on for 3 hours.
Experiment 1	66·39	—	
IX. Reduction to ammonia by heating ethereal solution with stannous chloride and hydrochloric acid; excess of stannous chloride estimated by titration with 1/10-normal iodine solution.			In all cases, the quantity of stannous chloride used is insufficient to account for the reduction of all the nitroglycerine present.
Experiment 1 at boiling point of ethereal solution	—	5·63 $SnCl_2$	
„ 2 „ „ „ „	—	6·40 $SnCl_2$	
„ 3 for 6 hours at 100° in sealed tube	—	9·76 $SnCl_2$	
„ 4 „ „ „ „	88·35	9·76 $SnCl_2$	
„ 5 „ „ „ „	81·49	9·66 $SnCl_2$	
X. Reduction of ethereal solution to nitric oxide by boiling with ferrous sulphate and sulphuric acid:			The nitric oxide was mixed with excess of air, the nitric peroxide produced collected in standard caustic soda solution, and the excess of alkali titrated with N/10 acid. It was found impossible to bring about the completion of the reaction event after prolonged boiling; whilst unchanged nitroglycerine invariably found its way into the absorption flask.
Experiment 1	34·60	—	
XI. Estimation of nitroglycerine as ammonia produced by the reduction of its saponification products with zinc iron and caustic soda.			Calculated to nitrogen this is—
Experiment 1	100·18	—	18·53 per cent. } Theory
„ 2	99·43	—	18·39 per cent. } 18·50 per cent.
„ 3	99·78	—	18·46 per cent. }

* These figures are calculated on the generally accepted equation for the saponification of nitroglycerine according to which 1 mol. of this substance requires 5 mols. of alkali.

† In aqueous solution, the saponification is far slower and less complete, whilst the presence of alcohol prohibits the use of hydrogen peroxide. The method recently published for the estimation of nitrogen in nitrocellulose by means of "nitron" (M. Busch, Ber. 38, 1906, 1401) is therefore not applicable.

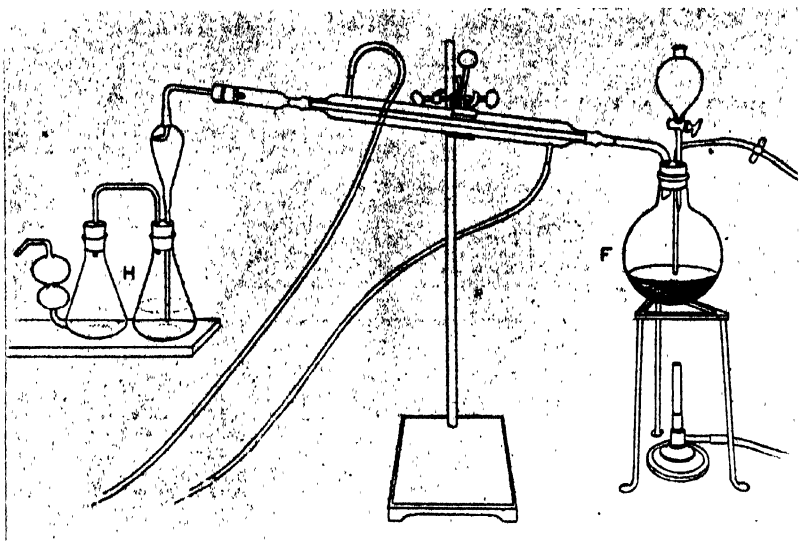

FIG. 2.

diagrams. Fig. 1 is the apparatus used for extracting and saponifying the nitroglycerine, and Fig. 2 that used for reducing the products to ammonia. It will be noticed that the apparatus used for extraction and saponification is fitted throughout with ground glass joints and supplied with a very efficient condenser—these precautions are necessary in order to avoid loss of nitroglycerine, which is readily carried away in the ether vapour.

The direct estimation of nitroglycerine in a cordite is carried out as follows:—A weighed quantity of the ground cordite, sufficient to yield about 2 grms. of nitroglycerine, is placed in a thimble in the Soxhlet extractor, A, which is fitted up as shown in the diagram. Eighty c.c. of absolute ether is poured into the flask, and extraction carried out in the usual manner. After the extraction of the cordite is complete, the thimble containing the residual nitrocellulose is washed with a little fresh ether, and removed from the extractor. The absorption flasks, C, containing 10 c.c. of N/10 acid are now affixed, and excess of sodium ethylate (about 50 c.c. of a solution prepared by dissolving 5 grms. of sodium in 100 c.c. of absolute alcohol) run into the flask little by little through the side tube, D. The reaction takes place rapidly, and is completed by warming on the water-bath for about six hours; its course may be followed by periodically drawing off small samples by means of the tap, E, and examining them for nitroglycerine by means of diphenylamine in sulphuric acid. The ether is then distilled up into the Soxhlet and run off by means of tap, the residue is dissolved in water and made up to 250 c.c., the aqueous Soxhlet and ether washings being also added to the solution.

Fifty c.c. of the solution are transferred to the flask, F, of the reduction apparatus (Fig. 2). Fifty grms. of a mixture of powdered zinc (2 parts) and reduced iron (1 part) are added together with 50 c.c. of 40 per cent. caustic soda solution and the ammonia distilled off in a slow current of air and collected in standard acid (about 75 c.c. N/10 acid) in the absorption flask, H. The excess of acid is then titrated back. One c.c. of N/10 acid corresponds to 0·00757 grm. of nitroglycerine.

The following examples, which show the nitrogen present as nitroglycerine, will serve to illustrate the degree of accuracy of the method. Nitrogen estimations were also carried out by Dumas' ultimate method on the original explosive and also on the nitrocellulose, separated by ether extraction, and the nitrogen present as nitroglycerine, calculated from these data, is given for comparison.

Explosive.	Nitrogen determinations by Dumas' method.			Nitrogen present as nitroglycerine.	
	Nitrogen in original cordite, &c.	Nitrogen in extracted nitrocellulose.	Percentage of nitrocellulose.	Calculated from results by Dumas' method.	Found by new method.
Experimental cordite F. 140	14·77	12·82	36·33	10·11	10·02
Experimental cordite 4296	15·53	13·22	31·83	11·32	11·35
Experimental cordite 2614	13·90	12·85	65·43	5·49	5·47
Blasting gelatine	17·21	11·81	8·26	16·24	16·00

The slight discrepancy (0·249) between the results obtained by the two methods when applied to blasting jelly is due to the fact that Dumas' method invariably gives high results when applied to this explosive; the new method is evidently accurate in this case also.

Our thanks are due to the Explosives Committee and the Director of Artillery for permission to publish these results.

Separation of solid bodies from liquids by cooling, and apparatus therefor. P. Porges, Vienna, and R. Neumann, Brünn-Königsfeld, Austria. Eng. Pat. 23,424, Nov. 14, 1905.

THE liquid to be cooled is introduced into a vessel in which a number of hollow bodies, through which the cooling medium is caused to flow, are arranged. These may be of any convenient shape so long as their exterior surfaces can be reached by a series of scrapers, mounted on a common shaft, and caused to rotate. The scrapers serve to keep the contents of the vessel agitated, as well as to remove the deposited solids from the surface of the cooling bodies.—W. H. C.

Evaporating apparatus; Vacuum ——. F. Jürgens, Sangerhausen, Germany. Eng. Pat. 18,130, Sept. 7, 1905.

UNITED STATES PATENTS.

Blast-flame furnace. B. E. Eldred, Bronxville, N.Y., Assignor to Combustion Utilities Co., New York. U.S. Pat. 821,994, May 29, 1906.

THE furnace consists of an inclined rotary combustion chamber, with means for supplying material to be calcined to the upper end, and a discharge outlet at the lower end. The main flame of the furnace, derived from a blast-nozzle, connected with a receptacle for powdered coal, is directed axially into the combustion chamber, and passes over the material in it, in a direction opposite to that in which the material is travelling. By means of an auxiliary nozzle, comprising two concentric pipes, the inner of which is connected with an air-compressor, and the outer with a fan-blower, a secondary flame is directed into the combustion chamber at an angle to the axis of the main flame, and directed on to the floor of the chamber. By this arrangement the main flame gives a region of relatively low temperature, and the secondary flame one of relatively higher temperature, near the discharge end of the furnace, and these can be relatively adjusted longitudinally of the furnace. By means of damper mechanism attached to the stack of the furnace, the position of the main flame can be varied within the combustion chamber.—W. C. H.

Kiln; Continuous ——. W. A. Butler, San Francisco, Cal. U.S. Pat. 822,580, June 5, 1906.

A SUCCESSIVE series of burning-chambers is arranged in the form of an elongated oval, with combustion-chambers in the lower part of the walls at each side. The combustion-chambers are separately supplied with fuel, and are inclined downward; they communicate with the burning-chambers by depressed channels at each side the floor, the products of combustion being direc upwards into the burning-chambers by deflecting wa Separate, damper-controlled air supplies are provic for both the combustion- and burning-chambers, a the latter are connected to the main flue to the stack damper-controlled gas passages. Any burning-cham in which the process is completed can be shut off fr its combustion-chamber by a "gate" or damper, a the partitions between the burning-chambers can be ea removed to allow access to the interior.—W. H. C.

Dryer. G. E. Chamberlain, St. Louis, Mo. U.S. P 822,185, May 29, 1906.

THE apparatus comprises a rotary drying chamber a a feed conveyor, geared together so as to move sim taneously. The material to be dried is supplied to feed conveyor, which is arranged in the lower port of a flue communicating with the drying chamber. Th is also a flue-cleaning conveyor in the bottom of the fl to deliver material into the cylinder in a position mingle with that delivered by the feed conveyor. —W. C. H

Drying chamber. A. Schröder, Assignor to A. Krau Berlin. U.S. Pat. 822,990, June 12, 1906.

SEE Fr. Pat. 357,768 of 1905; this J., 1906, 113.—T. F.

Suction-filter. P. Argall, Denver, Colo. U.S. P 822,812, June 5, 1906.

THE claim is for a series of suction-filters with porc sides, and provided with inlet and outlet pipes, the lat being connected to a suction-producing apparatus. T filters are rigidly supported, and are enclosed in a remc able open-ended tank, which, when in position, has open end closed by a fixed plate at one end of the ser of filters. The liquid to be filtered is fed into the tar and the clear portion is drawn through the porous filte leaving the sludge adhering to their outer surfaces. series of tanks to hold the various fluids, and a mechani for moving the enclosing tank are included in the clair —W. H. C.

Separators; Liner for centrifugal liquid ——. Ljungström, Assignor to Aktiebolaget Separat Stockholm. U.S. Pat. 822,904, June 12, 1906.

SEE Eng. Pat. 9417 of 1905; this J., 1906, 523.—T. F.

II.—FUEL, GAS, AND LIGHT.

(*Continued from page* 583.)

Coal briquettes and briquette pitch; Chemical methods judging ——. E. J. Constam and R. Rouge Gluckauf, 1906, **42**, 481; Chem.-Zeit., 1906, **30**, Re 178—179.

1. *Yield of coke.*—After examining and comparing vario methods, the authors state that the crucible used for t Muck test must be at least 24 mm. across the botto or the results will come out 2—3 per cent. of coke t high. The Bochum intumescence test is less delica the yield of coke being on the average 1—3 per cer lower, but the results agree more closely with gasificati tests made in gasworks. The least concordant resu are furnished by the Belgian method (heating for h an hour in a covered porcelain crucible in a gas muffl On the other hand, the American method (1 grm. undried substance heated for seven minutes in a cover platinum crucible weighing 20—30 grms., and plac about 6—8 cm. above a burner nozzle giving a Buns flame 20 cm. high) gives a coke yield most nearly appro mating to practical working.

2. *Briquette pitch.*—The Bochum method is best f

determining the amount of coke residue, but owing to the difficulty of burning the final traces of volatile matter, a second flame should be directed close to the opening in the crucible lid, to see whether ignition occurs. The yield of coke afforded by the pitch is important, any yielding 45 per cent. being unsuitable. The percentage of constituents soluble in carbon bisulphide forms a good criterion of the proportion of binding constituents present. The yield of such constituents varies between 60·4 and 95 per cent., with 79·8 per cent. as the average. Furthermore, pitch with a lower heating value than 8550 cal., and over 5 per cent. of water, is of low binding power.

3. *Determination of the percentage of binding medium in briquettes.*—The substance is extracted twice for 24 hours in a Soxhlet apparatus, with carbon bisulphide, *i.e.*, using a fresh quantity of bisulphide each extraction, and the residue dried over phosphorus pentoxide *in vacuo* for about three days. When the extract falls below 5 per cent. of the total weight of substance, the briquettes are deficient in pitch. A complete calorimetric and chemical examination should also be made. The calorific value should be not less than 7700 heat units (calculated to dry substance); ash content not over 8 per cent.; percentage of matter soluble in carbon bisulphide not less than 5 per cent.; and volatile constituents not less than 16 per cent.—C. S.

Acetylene burners; Some incandescent —— : their behaviour and illuminating power. F. H. Leeds. J. Gas Lighting, 1906, **94**, 781—784.

In the ninety-two German villages now provided with public supplies of acetylene, incandescence lighting is very largely used. The Schimek burner, recently introduced, has been used by the author in his experiments, and is found to behave satisfactorily. At a pressure of 4 ins., and a consumption of 0·472 cb. ft. (13·35 litres) per hour, a "10 litre" burner gave an illuminating effect of 46·0 candle-power, equal to an efficiency of 97·4 candles per cb. ft. On increasing the pressure, the efficiency increased very much, amounting to 106·4 candles per cb. ft. at 4·5 ins., and 113·7 candles per cb. ft. at 5 ins.; but at the latter pressure the burner began to "roar" slightly. Using a "15 litre" burner, at 4 ins. pressure and a consumption of 0·663 cb. ft. (18·8 litres) per hour, the candle-power was 70·0, equal to 105·5 candles per cb. ft. An efficiency of 100 candles per cb. ft. can therefore be obtained easily, even with small incandescence acetylene burners. Mantles which have been used at abnormally high pressures (4·5—5 ins.), and have thus shown higher efficiencies, appear to maintain these efficiencies when subsequently used at 4 ins., possibly because the mantles have shrunk to the most advantageous shape at the higher pressures.—H. B.

Carbon; Alterations of condition experienced by amorphous ——, under the influence of temperature, and under the action of oscillations of temperature. O. Manville. VII., page 637.

English Patents.

Tar [for briquettes, &c.]; Method of solidifying —— S. G. Coulson, Rotherham. Eng. Pat. 4427, Feb. 23, 1906.

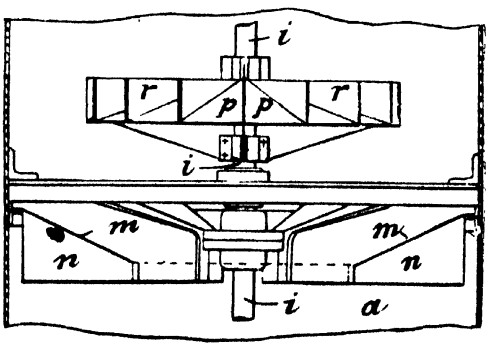
The process claimed is an improvement on that described in Eng. Pat. 2102 of 1904 (this J., 1904, 780), and consists in eliminating the crude naphtha by distillation before treating the tar with concentrated sulphuric acid.—D. B.

Oxygen; Producing ——, for internal combustion engines. P. Winand, Cologne. Eng. Pat. 3121, Feb. 8, 1906. Under Int. Conv., Feb. 9, 1905.

For working internal combustion motors under exclusion of air, an oxygen carrier, such, for instance, as potassium chlorate, preferably mixed with a liquid to facilitate its regular feeding, is supplied, continuously or at intervals, to the place of production, in proportion to the quantity of oxygen required. Hot combustion gases, or combustible substances, are conveyed to the place of delivery of the oxygen carrier, in order to provide, by their heat of combustion, for the steady evolution of oxygen from the latter. The invention is described as applicable to vessels that are to be propelled in a submerged condition, such as submarines.—E. S.

Carbonisation of coal in vertical or inclined retorts, and apparatus therefor. H. W. Woodall, Wimborne, and A. McD. Duckham, Upper Parkstone, Dorset. Eng. Pat. 10,954, May 25, 1905.

To regulate the quantity of steam that passes up through the coal, on using a vertical or inclined retort the lower end of which dips into water, a branch or by-pass pipe is provided, connecting the lower part of the retort, near the surface of the water, with the gas-outlet pipe at the top of the retort. By adjusting a valve on the by-pass pipe, the whole, or any desired proportion, of the steam generated by the hot coke may be led off, and prevented from rising through the fuel.—H. B.



Gas producer plants; Suction ——. T. A. Goskar and L. Burn, Charlton, Kent. Eng. Pat. 11,725, June 5, 1905.

Water is sprayed into the cylinder of the engine connected to the producer, so as to generate steam in the exhaust gases, and the latter are then admitted into the producer along with just sufficient air to generate the required heat by combustion. In this manner the heat of the exhaust gases is utilised to generate steam, and the carbon dioxide they contain is converted into carbon monoxide. The plant is preferably provided with exhaust silencers, serving as anti-pulsation chambers, before the producer and the inlet of the gas-engine cylinder.—H. B.

Gas producers; Impts. in ——. L. Wilson, Greenock. Eng. Pat. 12,563, June 17, 1905.

In a gas producer having a superheating chamber through which the gases are led, so as to convert tarry matters into permanent gases, the superheating chamber is provided with apertures to admit steam or air blasts, for the purpose of cleaning out the passages in the chamber.—H. B.

Absorption or solution of soluble substances by liquids; Apparatus for promoting the ——, suitable (inter alia) for use in the purification of illuminating and other gases. F. Clark, Southend-on-Sea. Eng. Pat. 11,776, June 5, 1905.

The gases to be washed are passed up a tower, the construction of which will be seen from the figure, which is a vertical section of a portion of the tower, and the washing or absorbing liquid flows down the tower. Through the centre of the tower, *a*, a shaft, *i*, passes, which is rotated by spur wheels from below, and which carries a number of superposed distributing cones, *p*, *p*, provided on their upper surfaces with vertical division plates, *r*, *r*. Between each of the rotating cones is fixed the frustum of an inverted cone, *m*, also having vertical division plates, *n*, and attached to the sides of the tower, *a*. The liquid and the gas are caused to alternately approach and recede from the centre of the tower, and at each change of direction, the gas is obliged to pass through a veil or film of the liquid.—W. H. C.

Tar; Apparatus for extracting ——, from illuminating gas. P. F. Holmes, E. D. Holmes, and E. G. Cameron, Huddersfield. Eng. Pat. 4230, Feb. 20, 1906.

TAR-EXTRACTING drums of the kind referred to in Eng. Pats. 25,493 of 1901 and 20,677 of 1903 are modified in construction by securing the sets of plates, constituting the drum, between corner-posts bolted to the drum top and cover-strips secured to the corner-posts, for the purpose of facilitating the cleaning of the drum and the alteration of the spacing or number of the plates.—H. B.

Vessels for containing gas under pressure; Impts. in ——. A. Boas, C. Rodrigues-Ely, and E. Gauthier, Paris. Eng. Pat. 4824, Feb. 27, 1906. Under Int. Conv., Oct. 12, 1905.

THE claim is for an improved method of closing the cylinders or vessels in which compressed gas is stored. The outlet pipe, provided with its valve, passes through and is secured to the vessel by the collar which holds the closing plug of the vessel in position; the outlet pipe also passes through the perforated closing plug. The outlet pipe is easily accessible for cleaning purposes, and the closing plug can be easily and safely loosened. Further, a filtering chamber is attached to the end of the outlet pipe which projects into the gas cylinder, so that the gas may be passed through any desired filtering agent. —W. H. C.

Gas calorimeters · Impts. in ——. S. E. Page, London. From H. L. Doherty, Madison, Wis., U.S.A. Eng. Pat. 8866, April 12, 1906.

THE calorimeter comprises a vertical, cylindrical combustion-chamber, the walls of which are constructed of four concentric cylinders forming three annular compartments, in the innermost and outermost of which water circulates; an annular tank, surrounding the combustion-chamber, and adapted to contain the gas to be tested; a Bunsen burner fixed centrally in the lower part of the combustion chamber, and supplied with gas from the annular tank; water-supply pipes, with constant-level devices, for maintaining a flow of water through the apparatus; and thermometers for indicating the temperatures of the inflowing and outflowing water, of the waste gases, and of the atmosphere. By means of a series of vertical baffle-plates arranged in the middle annular compartment surrounding the combustion chamber, the products of combustion are caused to pursue a zig-zag course, so as to be cooled to the atmospheric temperature before escaping. The cooling water from the combustion-chamber flows into the annular tank, the heated water thus driving out its own volume of gas. The calorimeter is used without a meter. On starting a test, the annular tank is first filled with gas, by filling it with water, and then admitting the gas to be tested, the water being run to waste. Water is now allowed to flow through the apparatus; as it fills the tank, the gas is expelled through the Bunsen burner, and is there burned, the water and gas streams being so regulated that the pressure within the tank remains constant, water displacing gas, volume for volume. The temperature difference between the inflowing and outflowing water gives the calorific value directly, irrespective of the actual rate of consumption of the gas, since, in a given time, the volume of water flowing through the annular compartment surrounding the combustion chamber is exactly the same as that of the gas burned.—H. B.

UNITED STATES PATENTS.

Gas producing and consuming apparatus. C. Ellis, New York, Assignor to Combustion Utilities Co., New York. U.S. Pat. 821,995, May 29, 1906.

IN the apparatus described, the gas is obtained from a producer, adapted to contain a deep bed of fuel, and burned in a metallurgical furnace, to which it is supplied through a heat-insulated pipe. The burned gases, or a portion of them, are drawn from the furnace through a heat-insulated pipe by means of a power-driven fan, and returned below the bed of fuel in the producer. On the suction side of the fan, is a valve-controlled air inlet, opening to the atmosphere, by which air is admixed with the burned gases prior to their introduction into the producer, to which regulated proportions of burned gases and cold air are thus supplied. (See also U.S. Pat. 813,629, Feb. 27, 1906; this J., 1906, 307.)—W. C. H.

Gas generator. A. H. Jones, Hartford City, Ind. U.S. Pat. 822,132, May 29, 1906.

THE gas-generating chamber is arranged on a supporting base, and is divided into several generating compartments to which oil and coal-dust are supplied, together with a mixing arrangement and compartment, into which the gas is drawn and mixed; there are "breaker walls" in the compartments, which are formed by transverse partitions in the generator, apertures at the lower ends of the partitions forming passages between the compartments. Means are provided for injecting coal-dust, and igniting it and the oil. The gas is passed into wet scrubbers arranged on the base, and then into dry scrubbers. Oil and steam are injected into one of the generating compartments by a centrifugal mixing and injecting device, consisting of a cylindrical casing, in which a turbine wheel is mounted, above which is a perforated plate. Steam is introduced through a pipe, tangential to the wheel, and oil is admitted through a pipe in the top of the casing, and a steam and coal discharge pipe is arranged in the side of the casing opposite the steam inlet, and communicates with the generating compartment.—W. C. H.

Gas producing apparatus. J. Bueb, Dessau, Germany. U.S. Pat. 822,246, June 5, 1906.

SEE Fr. Pat. 356,974 of 1905; this J., 1906, 11.—T. F. B

Gas; Revolving kiln for generating ——. S. E. Sieurin, Högenäs, Sweden. U.S. Pat. 822,394, June 5, 1906.

SEE Fr. Pat. 356,615 of 1905; this J., 1906, 11.—T. F. B.

Gas furnace; Regenerative ——. F. Siemens, Dresden, Germany. U.S. Pat. 822,486, June 5, 1906.

SEE Eng. Pat. 5866 of 1903; this J., 1904, 317.—T. F. B.

Gas; Process of manufacturing ——. L. P. Lowe, San Francisco, Cal. U.S. Pat. 822,531, June 5, 1906.

OIL is sprayed by means of a jet of compressed combustible gas into a chamber filled with refractory material which has been previously raised to a high temperature. When the temperature has fallen to a point at which the oil is no longer gasified, the supply is cut off, and the refractory material heated again by admitting air, and burning the residual oil along with a portion of the gas produced. These operations are repeated alternately as long as it is desired to produce gas.—W. H. C.

FRENCH PATENTS.

Furnaces; Device for consuming smoke in ——. N. Birck. Fr. Pat. 362,116, Jan. 2, 1906

ON either side of the furnace is arranged a series of cast iron boxes of [-section, through which air ascends from below the fire-bars, and is discharged above the layer of fuel in such a manner that the mutual impact of the two air currents causes the smoke to descend on to the burning fuel, and be consumed. The boxes are set in refractory brickwork, and means are provided for bonding them into the brickwork and each other, as well as for preventing the ashes, &c., falling through the grate from choking the inlets.—C. S.

Gas generator for high or low combustion, with apparatus for drying damp fuel. Maschinenfabrik und Mühlenbauanstalt G. Luther Akt.-Ges. Fr. Pat. 362,267, Jan. 9, 1906. Under Int. Conv., Dec. 13, 1905.

SEE Eng. Pat. 1295 of 1906; this J., 1906, 464.—T. F. B.

GERMAN PATENT.

Gases, especially producer gas; Process for filtering ——, through layers of fibrous substances. H. Apel. Ger. Pat. 166,613, Nov. 22, 1904.

THE gas is passed through a layer of coarse-fibred absorbent

material ("wood wool") to remove tarry matter, then through a dense layer of fibrous material, such as horsehair, to separate particles of dust, and afterwards through a layer of sponge or similar material to remove moisture. If desired the gas may be finally passed through a layer of felt or similar material.—A. S.

Petroleum in New Zealand. Times Finan. Supp., June 25, 1906. [T.R.]

In several places in New Zealand, but notably at New Plymouth on the west coast of the North Island, and near Greymouth on the west coast of the South Island, there are indications that reservoirs of oil exist at considerable depths from the surface. In the New Plymouth district, oil was discovered near the sea coast, some miles from the base of the extinct volcano known as Taranaki, or Mount Egmont. The history of boring for petroleum in that district extends back to the year 1865. It was one of general failure. Further unsuccessful efforts were made to obtain British capital to continue the boring. Eventually a New Zealand syndicate was formed. A bore was put down in the vicinity of the abandoned workings to a depth of 905 ft.; oil was struck, but water was also present in the bore, and as the water rose and fell with the tide, it was evident that there was a fissure running out to sea. Operations were continued in another direction, and a bore put down to 905 ft. yielded a flow of ten barrels a day. The continual falling in of a soft layer of "papa" rock, however, soon stopped the flow of oil. In 1896 a fresh bore was put down, and, at a level of 1976 ft. a considerable flow of oil was struck; but again the water interfered with the flow, and, eventually, the derrick and works were destroyed by an explosion and fire. More recently the operations were continued, and, a few days ago, it was announced that all difficulties had been overcome, and that excellent oil, with a total absence of water, was flowing from the well. The first flow was at the rate of about 30 barrels a day, but there was a great quantity of mud and sand mixed with the oil. On April 30, however, it was found that there was an enormous pressure of gas, and that the oil was flowing at the rate of 400 barrels a day. The bore is down to a depth of 2331 ft. The company has secured rights over 5000 acres of land in the vicinity, and, as the present storage capacity of 10,000 galls. has been almost filled, the well has, for the present, been sealed down. The company, however, intends to erect a refinery, and hopes within eighteen months to have six other bores sunk and working. The company's expert anticipates a yield of 4000 or 5000 barrels a day from the present bore.

Asphaltum; Action of light on ——. V. Vojtech. XXI., page 654.

Erratum.

Petroleum production of California. For. Off. Ann. Series. No. 3564. This J., May 31, 1906, p. 467. Instead of "gallons" *read* "barrels" throughout first paragraph.

English Patent.

Acetone; Manufacture of ——. L. A. A. Pagès and E. C. A. Camus, Paris. Eng. Pat. 8757, April 11, 1906. Under Int. Conv., April 14, 1905.

The invention consists in causing a continuous current of distilled pyroligneous acid to pass over a heated acetate, capable of forming acetone by dry distillation, which acetate is continuously regenerated by the vapours of acetic acid contained in the pyroligneous acid, and then again decomposed by heat.—D. B.

German Patent.

Mineral oils; Process for working up ——. L. Landsberg. Ger. Pat. 166,452, Sept. 24, 1904.

The oils are extracted with acetone or its homologues, the solution is separated from the tarry and asphaltum-like constituents which remain undissolved, and the solvent recovered by distillation. The process is stated to be specially suitable for the treatment of crude petroleum containing only small quantities of light constituents (benzine, illuminating oils, &c.), and also for heavy oils and residues.—A. S.

IV.—COLOURING MATTERS AND DYESTUFFS.

(*Continued from page* 585.)

Gallocyanine dyestuffs; Condensation of ——. *with aminosulphonic acids.* E. Grandmougin. Z. Farben.-Ind., 1906, **5**, 201.

If gallocyanine dyestuffs, such as Prune or Celestine Blue, be heated on the water-bath in aqueous suspension with sulphanilic acid, *o*- or *p*-toluidinesulphonic acid, β-β-naphthylaminesulphonic acid, or other amino-sulphonic acids, new dyestuffs are formed which can be printed on cotton with a chromium mordant, or dyed on wool from an acid bath, or on a chromium fluoride mordant. The dyeings obtained are much bluer than those of the original substances, but possess, it is stated, little technical interest, as they are not fast to light.—H. L.

1.4-*Anthraquinone.* C. Liebermann. Ber., 1906, **39**, 2089—2090.

A reply to Lagodzinski with reference to the discovery of the above compound (this J., 1906, 300 and 530).

Colouring matter [dyestuff] of the triphenylmethane series; Manufacture of a new ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 22,021, Oct. 28, 1905.

See Fr. Pat. 359,002 of 1905; this J., 1906, 369.—T. F. B.

Dianisidine and diphenetidine; Manufacture of disulphonic acids of ——. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 22,697, Nov. 6, 1905.

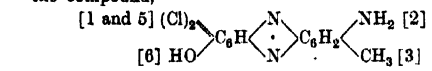
See Fr. Pat. 359,214 of 1905; this J., 1906, 424.—T. F. B.

Colouring matters containing halogen [Anthracene dyestuffs]; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 22,519, Nov. 3, 1905.

See Seventh Addition, dated Nov. 9, 1905, to Fr. Pat. 349,531 of 1904; this J., 1906, 471.—T. F. B.

United States Patent.

Dyestuff; Vat ——, *and process of making same.* K. Schirmacher, Assignor to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on the Maine, Germany. U.S. Pat. 823,294, June 12, 1906.



See Fr. Pat. 360,292 of 1905; this J., 1906, 471.—T. F. B.

French Patents.

Dyestuffs; Process for making red to violet sulphide ——. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 360,437, Feb. 23, 1905.

Compounds containing sulphur but free from halogen elements are obtained by heating halogen-substituted hydroxyazines with alkali sulphides. These, when heated in alkali sulphide solution with sulphur, are converted into sulphur dyestuffs of shades varying from red to violet. The halogenated hydroxyazines may be directly trans-

formed, in one operation, into the sulphur dyestuffs by heating them with alkali polysulphides. They yield dyestuffs at temperatures considerably lower than do the corresponding halogen-free hydroxyazines; thus, the compound,

gives at 100°—108° C. a red dyestuff free from chlorine, while the compound

requires to be heated at 130° C. to yield a brownish-purple sulphur dyestuff. A mixture of dibromosafraninone (30 parts), crystallised sodium sulphide (150 parts), and sulphur (75 parts), gives when heated at 140°—150° C. a dyestuff which, from an alkali sulphide bath, dyes cotton in violet shades.—E. B.

Dyestuff; Process of making a bisulphite compound of the [azo] —— of Fr. Patent 304,694. Farbwerke vorm. Meister, Lucius, und Brüning. Fr. Pat. 361,322, April 3, 1905.

SEE U.S. Pat. 795,058 of 1905; this J., 1905, 885.—T. F. B.

Lakes [from azo dyestuffs]; Production of red ——, fast to light. L. Cassella und Co. Fr. Pat. 361,313, March 31, 1905. XIIIA., page 644.

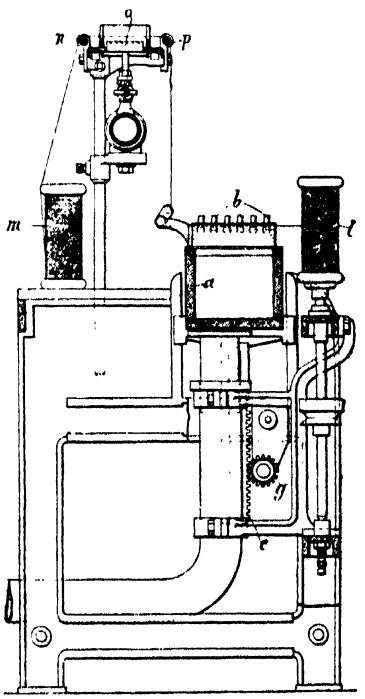
Anthraquinone dyestuffs; Manufacture of new ——. Farbenfabriken vorm. F. Bayer et Cie. First Addition dated Dec. 5, 1905, to Fr. Pat. 355,326, June 17, 1905 (this J., 1906, 1223).

BY nitration of the urethanes of amino-anthraquinone or of their derivatives, dinitro derivatives having the nitro groups in the same benzene nucleus are obtained; and by nitration of the diurethanes of the diamino-anthraquinones, the tetranitro derivatives are produced. By hydrolysis of these nitro-urethanes the corresponding polynitrated amino-anthraquinones are produced which are of great value in the preparation of dyestuffs. The nitro-amino-anthraquinones mentioned above give tri- and hexa-amino-anthraquinones on reduction.

Example.—Ten kilos. of the urethane of β-amino-anthraquinone are dissolved in 50 kilos. of nitric acid (95 per cent.), and the solution heated to 40° C. for half an hour until the nitro derivative, precipitated by addition of water to a sample of the reaction mixture, dissolves to an almost colourless solution in concentrated sulphuric acid. The whole mass is then thrown into water, and the precipitate purified by crystallisation from glacial acetic acid. The urethanes are hydrolysed by heating on a water-bath with ten times their weight of sulphuric acid (66° B.) until the evolution of carbon dioxide has ceased. The nitrated amino-anthraquinones are precipitated by running the mixture into ice water. The tri- and hexa-amino-anthraquinones are produced by treating the nitro compounds with reducing agents such as sodium sulphide, zinc dust and alkali, &c.—A. B. S.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

(*Continued from page* 586.)



α-Naphthylamine Claret; Discharging of ——, with aid of iron salts. R. Koechlin. Rev. Gen. Mat. Col., 1906, 10, 166—167.

INSTEAD of adding a large amount of ferric citrate, sodium nitrite, and sodium ricinoleate to the hydrosulphite-formaldehyde discharging-mixture (see Baumann and Thesmar, this J., 1906, 371 and 473), it is, according to the author, cheaper first to prepare the cloth with Turkey-red oil, and to add to the hydrosulphite-formaldehyde only a small quantity of a ferrous salt, *e.g.*, 5 grms. of ferrous sulphate together with 20 grms. of sodium nitrite. Such a mixture may be kept for at least a fortnight in cold weather. Ferrous nitrite, which is formed in the printing mixture, is an unstable salt subject to spontaneous decomposition, with evolution of nitric oxide or, in the presence of hydrosulphite, of nitrous oxide. The printing mixtures are ineffective as soon as ferrous nitrite is no longer present, but as the decomposition is slow, they may be kept for some time. The printing mixture is much more stable and thoroughly effective if the components of ferrous nitrite are separated. A perfectly pure white is produced, for instance, by printing a hydrosulphite-formaldehyde paste containing only 10 grms. of sodium nitrite per litre, on to cloth previously prepared with a solution containing 10 c.c. of neutralised ferric citrate and 50 grms. of sodium ricinoleate per litre. The reverse method, however, *viz.*, printing a mixture of hydrosulphite-formaldehyde with ferric citrate on to cloth prepared with sodium nitrite and sodium ricinoleate, gives very imperfect results. The author points out that in general the presence of sodium ricinoleate, which acts as a solvent, is advantageous, as a purer white is obtained, particularly on unmercerised cloth. Mercerised cloth is more readily discharged, and oiling is therefore less necessary.—H. L.

Copper alkali cellulose. W. Normann. XIX., page 652.

ENGLISH PATENTS.

Machine; Glossing and gassing ——, for silk and other fine threads. C. Mann, Waldshut, Germany. Eng. Pat. 22,940, Nov. 8, 1905. Under Int. Conv., Nov. 11, 1904.

IN the drawing showing the apparatus in front view, the dust-box, *a*, rests on toothed racks, *e*, which can be moved correspondingly up and down the entire length of the reel by means of a shaft provided with a toothed wheel, *g*, and receiving a forward and backward motion. The thread travels from the spool, *m*, over the bar, *n*, to the burner, *o*, and over the rod, *p*, to the glossing head, *b*. It then passes in a straight line to the spool, *l*,

on which it is wound up. By this arrangement breakages are prevented, as the thread is always exposed to uniform tension.—D. B.

UNITED STATES PATENTS.

Wool-scouring machine. J. H. Tillinghast, Stockton, Cal. U.S. Pat. 821,139, May 22, 1906.

THE machine comprises a tank in which is a pair of forks consisting of fork-bars with tines extending therefrom. The fork-bars are mounted in carrier-bars through which a transverse shaft passes. Cams on the shaft engage with rollers on the carrier-bars, whereby a vertical to-and-fro motion is imparted to the latter. A horizontal to-and-fro movement is also imparted to each fork in succession, and means are provided for regulating the movements so that the forks do not touch each other when passing in opposite directions. At the end of each forward movement, the fork-bar is caused to rotate in the carrier-bar, whereby an upward movement is imparted to the tines of the fork, in order to enable them to scoop up the wool. The wool is fed towards the forks by a rake consisting of a transverse bar with teeth extending therefrom, and provided with means for imparting an upward scooping movement to the teeth.—A. S.

Wool-scouring machine. T. A. Jones, Essendon, near Melbourne. U.S. Pat. 822,954, June 12, 1906.

SEE Eng. Pat. 17,026 of 1905; this J., 1906, 473.—T. F. B.

Silk; Apparatus for ungumming ——. P. Schmid, Basle, Switzerland. U.S. Pat. 822,774, June 5, 1906.

SEE Addition of Jan. 21, 1905, to Fr. Pat. 345,173 of 1904; this J., 1905, 475.—T. F. B.

FRENCH PATENTS.

Silk, artificial; Rendering ——, waterproof and non-inflammable. P. Germain. Fr. Pat. 360,396, Feb. 22, 1905.

ARTIFICIAL silk, as it is manufactured, and before it is reeled and twisted, is immersed first in a bath of a salt, such as ammonium phosphate, ammonium bicarbonate, or magnesium bicarbonate, capable of yielding, when heated by a flame, a gas or gases which have the property of hindering combustion. It is next passed through a solution of "colourless celluloid and nitrocellulose," to cover the fibres with a waterproof coating, after which it is reeled and twisted.—E. B.

Silk and other fine threads; Glossing and gassing machine for ——. C. Mann. Fr. Pat. 359,059, 1905.

SEE Eng. Pat. 22,940 of 1905; preceding these.—T.F.B.

Wool-carbonising device. E. Dupont. Fr. Pat. 360,457, Dec. 12, 1905.

THE carbonising chamber is provided with two lattice-work shelves, with a set of heating pipes below the lower shelf, and with a receptacle for holding "acid." It communicates with a chimney that can be closed by a damper. The acid-receptacle is furnished with a heating coil. The wool to be carbonised is introduced through doors in the side of the chamber, and is spread upon the lattice-work shelves, the chimney-damper is closed, and a heating agent is supplied to the heating pipes and to the coil in the acid-receptacle. The hot acid vapours rise through the wool on the shelves, escape through a pipe in the top of the chamber, and are returned by a fan through another pipe, which discharges them into the chamber between the heating pipes and the lower shelf.—A. S.

Tanning of skins and mordanting tissues; Substance for use in ——. O. H. Nowak, E. N. Eaton, and J. M. McVean. Fr. Pat. 360,854, Dec. 22, 1905. XIV., page 647.

Fabrics; Blocks for embossing or printing ——. E. Roudet. First Addition, dated Feb. 21, 1905, to Fr. Pat. 348,836 of Feb. 24, 1904 (this J., 1905, 617).

INSTEAD of the cylindrical or prism-shaped "pins" of uniform diameter described in the main patent, "pins" of various diameters, along with intervening sheets of metal of various thicknesses, are employed to compose the bodies of printing blocks. The sheets of metal are either straight or curved, and are placed, parallel to the axes of the pins, with the ends of the latter projecting beyond their ends, to form the pattern which is to be impressed. They are chiefly intended for use in the decoration of velvets. —E. B.

Fabrics; Process for making ——, impermeable. E. Geisenberger. Fr. Pat. 361,284, Dec. 21, 1905. Under Int. Conv., Sept. 20, 1905.

To render fabrics such as are employed for balloons impermeable to air, gas, moisture, &c., the material is placed in a closed vessel, and submitted to the action of a vacuum to remove the various volatile substances contained in the pores of the fibres. Heat is sometimes applied at the same time. The liquid employed for making the fabric impermeable is then run into the vessel by some suitable device, and fills up the pores and spaces between the fibres. This process may be repeated if necessary either with the same or another liquid, after which the excess is removed, and the fabric dried. Various substances can be employed, such as fats, varnishes, tannin, rubber, silicates, &c., or the fabric may be soaked in gelatin, and then tanned.—A. B. S.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

(*Continued from page* 532.)*

ENGLISH PATENT.

Leather; Printing on ——. M. C. Lamb and J. D. G. Rennie, London. Eng. Pat. 11,049, May 26, 1905.

To print or dye leather in pattern or design in one or more colours by the use of coal-tar and natural dyestuffs, the latter are applied in the form of ink in alcoholic or aqueous solution either alone or in conjunction with a thickening agent, such as gelatin, gum tragacanth, linseed, farina, starch alginates, soaps, "sulphated" oils, and the like. The inks are applied to the relief surface from which an impression is to be taken by any suitable method.—D. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

(*Continued from page* 580.)

Hydrofluoric acid. E. Deussen. Z. anorg. Chem., 1906, **49**, 297—300.

HYDROFLUORIC acid solutions behave like those of the other acid halides: weak solutions gradually become concentrated on distillation, strong solutions gradually weaken, till an acid of constant composition and boiling-point ultimately distils. At 750 mm. pressure this acid contains 43·2 per cent. of hydrogen fluoride, and boils at 111° C. Its sp. gr. at 18° C. is 1·138.—J. T. D.

Calcium sulphate; Solubility of ——, in magnesium sulphate solutions. F. K. Cameron and J. M. Bell, J. Physical Chem., 1906, **10**, 210—215. Chem. Centr., 1906, **1**, 1776.

WEIGHED pieces of selenite ($CaSO_4.2H_2O$) were fixed to the ends of pieces of glass rod, and these were passed through corks closing flasks containing magnesium sulphate solutions of different concentrations. The flasks were rotated in a horizontal position until the selenite was no longer dissolved. The results obtained at 25° C. with solutions ranging from a saturated solution of crystallised

magnesium sulphate, $MgSO_4,7H_2O$, to pure water, are shown in the following table:—

Sp. gr. at 25° C.	Magnesium sulphate. grms. per litre.	Calcium sulphate. grms. per litre.
1·0032	0·00	2·046
1·0055	3·20	1·620
1·0118	10·64	1·471
1·0419	42·68	1·558
1·0626	64·14	1·608
1·1190	128·28	1·627
1·1377	149·67	1·597
1·1537	171·2	1·474
1·2095	232·1	1·254
1·2624	298·0	0·860
1·3028	355·0	0·501

These results, together with others obtained previously, show that the injurious effect on the solubility of calcium sulphate of different sulphates increases with rising atomic weight in the series: $H^{\cdot}$, $Mg^{\cdot\cdot}$, $NH_4^{\cdot}$, $K^{\cdot}$, $Na^{\cdot}$. —A. S.

Potassium ferricyanide; Reduction of ——. D. Venditori. Atti. R. Accad. dei Lincei Roma, 1906 [5], **15**, 370—373.

ACCORDING to Williamson (Annalen, **57**, 237) the reduction of potassium ferricyanide by hydrogen sulphide proceeds according to the equations:—

$$8K_3Fe(CN)_6 + 3H_2S = 6K_4Fe(CN)_6 + 2H_3Fe(CN)_6 + 3S = 6K_4Fe(CN)_6 + 2Fe(CN)_3 + 6HCN + 3S.$$

The author finds, however, that there is formed, together with potassium ferrocyanide, a greenish precipitate, changing to bright blue. This precipitate, when freed from adhering sulphur, proved to be potassium-ferrous ferrocyanide, $K_2Fe_2(CN)_6$. It yields ferrous hydroxide and potassium ferrocyanide when boiled with caustic potash solution. One hundred parts of potassium ferricyanide yield 71·28—73·9 parts of potassium ferrocyanide, and 17·82—18·4 parts of potassium-ferrous ferrocyanide, corresponding approximately to the equation:—

$$6K_3Fe(CN)_6 + 3H_2S = 4K_4Fe(CN)_6 + K_2Fe_2(CN)_6 + 6HCN + 3S.$$ —A. S.

Copper sulphate; Decomposition of ——, *by methyl alcohol.* V. Auger. Comptes rend., 1906, **142**, 1272—1274.

COPPER sulphate, either crystallised or anhydrous, is decomposed by methyl alcohol at all temperatures from 0° C. to the boiling point of the alcohol. With small proportions of methyl alcohol, the salt, $CuSO_4,CH_3OH$, is obtained, mixed with traces of basic copper sulphate. As the quantity of alcohol is increased, the amount of basic salt formed rises rapidly, with the simultaneous decomposition of the methyl salt. Zinc sulphate also gives a notable quantity of basic salt when treated with methyl alcohol, whilst cobalt and nickel sulphates yield but traces. Ethyl alcohol is much more feeble than methyl alcohol in its action on copper sulphate.—W. P. S.

Cæsium; Direct oxidation of ——. *Properties of cæsium peroxide.* E. Rengade. Comptes rend., 1906, **142**, 1149—1151.

EVEN when perfectly dry, cæsium unites at ordinary temperatures with perfectly dry oxygen, the reaction being so violent, even when the pressure of the oxygen is only a few centimetres of mercury, that the metal and its oxide become incandescent. As the temperature is lowered, the reaction becomes less violent, and at —80° C. cæsium only tarnishes slowly in dry oxygen.

If, after the violence of the reaction at ordinary temperature has subsided, the product be heated in a stream of dry oxygen, it absorbs more of the gas, and yields ultimately a fused mass which on cooling becomes a yellow crystalline substance of formula Cs_2O_4. This peroxide melts, in an atmosphere of oxygen, at 515° C. It is readily dissociated, decomposes water with formation of cæsium hydroxide and hydrogen peroxide, and evolution of oxygen, yields cæsium carbonate and oxygen when heated in a stream of carbon dioxide, and is reduced by hydrogen at 300° C., with production of cæsium hydroxide, water, and oxygen.

The dry peroxide has no action on the aluminium boat in which it is formed, but attacks the metal rapidly if any moisture be present.—J. T. D.

Carbon; Alterations of condition experienced by amorphous, ——, *under the influence of temperature, and oscillations of temperature.* O. Manville. Comptes rend., 1906, **142**, 1190—1193.

A SPECIMEN of crayon charcoal ("fusain"), containing 89 per cent. of carbon, was powdered, sifted, and freed from occluded gas by heating *in vacuo*. When this charcoal was heated in a current of oxygen (about 1 litre per hour), carbon dioxide and carbon monoxide were produced, the temperatures of formation of the two compounds being 85° C. and 140° C., respectively. It was found that if the carbon were now heated *in vacuo* from 15° C. to 350° C., and then allowed to cool slowly, the temperatures of formation of its oxidation products were displaced in a definite manner, and after repeating these operations a certain number of times, attained constant values different from those originally observed. Thus, after heating *in vacuo* from 15° to 350° C., twenty times, followed in each case by slow cooling, the temperatures of formation of the carbon dioxide and carbon monoxide had attained constant values of 240° C. and 300° C. respectively. On now heating the carbon *in vacuo* to 450° C., and cooling slowly, the temperatures of formation of the oxidation products were considerably reduced, *viz.*, to 97° and 220° C., respectively; and then on again subjecting the carbon to a fresh series of oscillations of temperature identical with the first series, the temperatures of formation were again displaced, attaining after twenty such oscillations, constant values slightly higher (245° C. and 307° C., respectively) than those observed previously.

It was further observed that the condition of amorphous carbon at a given temperature differs according to whether that temperature has been reached by heating or by cooling. On cooling from a higher temperature, the rate of evolution of carbon dioxide is much greater at a given point than on heating from a lower temperature; for example, with the specimen of carbon under investigation, carbon dioxide is first formed at 85° C. on heating the carbon from the ordinary temperature, whilst on cooling, evolution of gas still takes place at 60° C.—A. S.

Bromine industry of the United States. Oil, Paint, and Drug Reporter, June 16, 1906. [T.R.]

THE bromine industry in 1905 was more active than in 1904, the output exceeding that of the preceding year by nearly 50 per cent., according to the annual report of the U.S. Geological Survey. The production in 1905 amounted to 1,192,758 lb., valued at $178,915, as compared with 897,100 lb., valued at $269,130, in 1904. The greater part of this product was made in Michigan, at Midland, Mt. Pleasant, St. Charles, and St. Louis.

In Michigan the brominiferous brines of commercial prominence come from the Marshall sandstone of the Upper Carboniferous, and contain from 0·1 to 0·3 per cent. of bromine. At Midland and Mount Pleasant are works manufacturing large quantities of bromine and bromides. The bromine in the brine varies in quantity from 0·1 to 0·2 per cent., and is freed from its usual combinations with alkali bases by an electric current. The free bromine is removed from the brine by a current of air, and is then absorbed by caustic soda. The output by this process in 1905 was more than half of the total product of the United States.

Bromine is made as a by-product in the salt industry at Pomeroy and Syracuse, Ohio, and at Hartford and Mason, W. Va. At Malden, on the Kanawha River, a few miles south-east of Charleston, W. Va., is another factory, also supplied from the Pottsville horizon.

At Pittsburg, Pa., there is a plant of average size which extracts bromine from brine derived from Pocono horizon. Pennsylvania was the pioneer state in the manufacture of bromine, and began it at Freeport, Armstrong County, in 1846. In Ohio the manufacture began at Pomeroy about 1868. It was also begun at Canal Dover, Tuscarawas County, in 1888, but has been abandoned at that point, and is now confined to Pomeroy and Syracuse.

The following table shows the increase of the production of bromine during the past decade:—

	Quantity. Pounds.	Value. $
1896	546,580	144,501
1898	486,979	126,614
1900	521,444	140,790
1902	513,893	128,472
1904	897,100	269,130
1905	1,102,758	178,914

Graphite discovery in Godavery. Bd. of Trade J., June 21, 1906. [T.R.]

According to the "Madras Mail," graphite in large quantities has been discovered at Seethareddipadu, in British territory, 70 miles from Godavery, and there is every probability of its proving remunerative. One of the leading European firms in Madras has sent out an expert to sink shafts and report results.

Large quantities of graphite have also been discovered on and below the hills between Perakoonds in the Nizam's Dominions and the Godavery River. No one has yet tried to prospect the place, but experts assert that any company will do well to work the graphite mines on the spot indicated. Graphite mines are also being worked about 80 miles from Godavery.

English Patents.

Sulphuric acid; Process for the concentration of ——. A. Gaillard, Barcelona, Spain. Eng. Pat. 23,841, Nov. 18, 1905.

See Fr. Pat. 359,442 of 1905; this J., 1906, 374.—T. F. B.

Endothermic chemical compounds; Process of and apparatus for producing ——. R. Pawlikowski, Görlitz, Germany. Eng. Pat. 26,728, Dec. 21, 1905.

See Fr. Pat. 361,119 of 1905; this J., 1906, 536.—T. F. B.

Cyanogen compounds; Recovering ——, *from waste waters, solutions, and the like, and rendering the liquids innocuous.* H. Noerdlinger and F. Noerdlinger, Flörsheim-on-Maine, Germany. Eng. Pat. 1764, Jan. 23, 1906. Under Int. Conv., Jan. 24, 1905.

The waste waters or very dilute solutions containing thiocyanogen or cyanogen compounds, are acidulated, for instance, with sulphuric acid (but not with nitric acid), and if thiocyanates are present, an oxidiser, such as manganese dioxide, is added. Through the solution, contained in a suitable apparatus, air is then blown, and the hydrocyanic acid evolved is condensed in alkaline or other solutions. According to one modification of the process, the liquid through which the air is blown is heated to about 50° C. The effluent may, when necessary, be neutralised by lime.—E. S.

United States Patents.

Burner gases [Sulphuric anhydride manufacture]; Process of purifying ——. R. Knietsch, Ludwigshafen on Rhine, Germany, Assignor to General Chemical Co., New York. U.S. Pat. 822,373, June 5, 1906.

See Eng. Pat. 15,948 of 1898; this J., 1899, 831.—T. F. B.

Sulphuric anhydride; Process of making ——. R. Knietsch, Ludwigshafen on Rhine, Germany, Assignor to General Chemical Co., New York. U.S. Pat. 823,472, June 12, 1906.

See Ger. Pat. 113,932 of 1898; this J., 1901, 360.—T. F. B.

French Patent.

Chromic acid; Electrolytic regeneration of ——, *in solutions of chromium salts.* M. Le Blanc. Fr. Pat. 362,195, Jan. 5, 1906. XII., page 643.

VIII.—GLASS, POTTERY, AND ENAMELS.

(*Continued from page* 590.)

Silicates [Glass]; Decomposition of ——, *[for analysis].* F. Hinden. XXIII., page 655.

Phosphorus; Qualitative test for —— Maurichéau-Beaupré. XXIII., page 655.

English Patents.

Rock quartz [Quartz glass]; Process for producing a molten mass of ——, *at a relatively low temperature.* J. Bredel, Höchst on the Maine, Germany. Eng. Pat. 15,630, July 31, 1905.

See Fr. Pat. 355,791 of 1905; this J., 1905, 1232.—T. F. B.

[*Pottery*] *Kilns; Impts. in construction of* ——. M. J. Adams, Stocksfield-on-Tyne, and J. Cannon, Scotswood-on-Tyne. Eng. Pat. 8440A, Oct. 12, 1905.

The claim is for improvements in the method of constructing kilns described in Eng. Pats. 6257 of 1891, 16,259 and 13,643 of 1902 (this J., 1903, 697). Two or more muffle-kilns are built side by side, with the fireplaces at the ends; the waste heat from one kiln passes through the flues of the adjacent kiln, and heats it. The temperature of the second kiln is finally raised to a finishing or glazing heat by feeding its own fireplace with fuel.—W. H. C.

United States Patent.

Silica [Quartz glass]; Process for fusing ——, *and for shaping the mass while plastic.* J. F. Bottomley, Wallsend-on-Tyne, and A. Paget, North Cray. U.S. Pat. 822,424, June 5, 1906.

See Eng. Pat. 18,437 of 1904; this J., 1905, 846.—T. F. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

(*Continued from page* 590.)

English Patent.

Wood and textile or fibrous substances; Chemically impregnating ——, *for preventing putrefaction, rot, and fungus.* F. Hasselmann, Munich, Germany. Eng. Pat. 11,294, May 30, 1905.

The wood or other substance to be impregnated is boiled with a lye containing in 30 parts 1 part of any waste salt of potassium or magnesium, 1 part of green vitriol (ferrous sulphate), and 1 part of aluminium sulphate. For the green vitriol, nickel sulphate may preferably be substituted, in the proportion of 1 part of the salt to 500 of lye.—A. G. L.

United States Patents.

Lime; Apparatus for burning ——. C. Ellis, White Plains, N.Y. U.S. Pat. 821,996, May 29, 1906.

The apparatus consists of a calcining chamber in the form of a vertical shaft, at the base of which is a gas producer with a deep bed of fuel. The gas enters the lower portion of the chamber, to which air is also supplied. The walls of the chamber are thick, and contain a flue through which products of combustion are withdrawn from the upper part, mixed with air, and returned to the producer by means of an injection apparatus.—W.C.H.

Fire-brick compound. T. P. Gourley, New York. U.S. Pat. 822,600, June 5, 1906.

About 80 parts of carborundum, 16½ parts of sodium silicate, 3½ parts of water, and ½ part of sulphuric acid are mixed together to form a plastic mass, which becomes hard when subjected to the action of heat.—A. S.

FRENCH PATENT.

Wood; Process of treating and colouring —— [by precipitation upon it of metallic oxides]. P. Merino. Fr. Pat. 360,703, March 7, 1905.

WOOD is coloured and prepared for use in the manufacture of works of art by the following series of operations:—(1) Treatment with an ammoniacal solution of a hydroxide of copper, cobalt, nickel, zinc, mercury, or other suitable metal. This has the effect of removing from the wood certain fermentable matters which, if left in it, would ultimately lead to its destruction. (2) Impregnation with a solution made by mixing together boiling solutions of sodium or potassium aluminate and barium chloride, allowing the mixture to cool, and removing the precipitated barium hydroxide. To this solution may be added a heavy coal-tar oil. The application of this solution is effected either by immersion in an open vessel, or in a closed vessel under pressure. The wood is afterwards treated with a solution of an alkali carbonate, which precipitates upon it "in the condition of oxide" the metal which has been applied. The process is completed by washing with a solution of an alkali sulphite. (3) The wood is next coloured, or its existing colour is modified, and its natural grain is at the same time rendered more prominent, by the application to it of suitable colouring agents, *e.g.*, cochineal carmine, litmus, orchil, coal-tar dyestuffs, metallic hydroxides, such as those of cobalt and nickel, in ammoniacal solution, or compounds such as ferric ferricyanide, ferric thiocyanate (sulphocyanide) &c.

The wood is thus "metallised," and rendered entirely unalterable by atmospheric influences. It is capable of taking an excellent polish. When prepared as described, but with the omission of the treatment with alkali carbonate and sulphite, it is, it is stated, in the form of thin sheets, flexible, and supple, like leather. In this condition it may readily be moulded into artistic shapes. To this end, the sheets are moistened on the back with starch paste, and sprinkled over with sawdust. They are then placed in heated moulds, and are strongly pressed. When dry they are removed, the hollow parts at their backs being filled with a paste composed of sawdust and glue size. They may, finally, be hardened by treatment with an alkali carbonate.—E. B.

X.—METALLURGY.

(*Continued from page* 593.)

Gold ores; Amalgamation of ——. T. T. Read. Bi-monthly Bull. Amer. Inst. Mining Eng., 1906, 467—495.

THE author discusses previous work on the amalgams, and describes experiments made with a view to determine the constitution of gold amalgams. The most satisfactory results were obtained by adding excess of finely-divided gold to mercury, heating at 100° C., filtering, treating with nitric acid of different strengths, and examining the residues by analysis, and under the microscope. The results obtained indicate that when the content of gold is high, a solid solution of mercury in gold (containing up to 13 atoms per cent. of mercury) is formed, which is isomorphous with gold. With lower proportions of gold, crystals belonging to the hexagonal system, and containing 17·44 atoms per cent. of mercury can be isolated; these represent either a compound of the two metals containing gold or mercury in solution, or a second solid solution. Ordinary amalgam consists of one or both of the foregoing, usually the former, mixed with an excess of mercury, which coats the particles, and causes them to cohere.

The amalgamation of gold ores appears to be a physical process; the grains of gold are wetted by the mercury, and are drawn beneath the surface of the film of mercury, and held against the plates, by the surface tension of the liquid mercury. Owing to diffusion into the metal of the plates, the amalgam often becomes strongly adherent. Silvered copper plates and Muntz metal plates are better than plain copper plates, the copper dissolved from the latter by the mercury having an injurious effect. Moreover the amalgam diffuses into Muntz metal plates only to a very slight extent. Plates coated with gold amalgam will retain a thicker film of mercury than any other kind of plates, and thus have the greatest "catching" power. Excessive scraping of the plates in actual working should be avoided, as the gain in daily yield of amalgam is more than counterbalanced by the loss of "catching" power. Changes of temperature have influence on the amalgamation process in various ways. Among the injurious effects are the increased solubility of salts and thus of precipitation of base metals in the mercury, and a diminution of the surface-tension and viscosity of the mercury, whereby the tendency of the mercury to "flour" is increased. On the other hand the wetting of the gold by the mercury, the "catching" power of the plates, and the capacity of the globules of mercury to coalesce are increased by rise of temperature. The author concludes that in the first place the working temperature should be kept constant, and when the influence of soluble salts in the ore can be neglected, as high a temperature as is possible economically should be maintained.—A. S.

Magnesium; Alloys of —— with silver. S. F. Zemczuznyj. Z. anorg. Chem., 1906, **49**, 400—414.

THE melting-point curve of magnesium-silver alloys shows four distinct points, *viz.*, a maximum at 820° C., corresponding to the compound, $MgAg$; two eutectic points at 756° C. (65·9 atoms per cent. of silver) and 469° C. (17·3 atoms per cent. of silver) respectively; and the transformation point (492° C., 22·57 atoms per cent. of silver) of the compound, Mg_3Ag. The latter compound is not indicated by a maximum on the melting-point curve, as it melts with decomposition at the transformation point. The compound, $MgAg$, forms solid solutions with both magnesium and silver, the limiting concentrations of the solutions being 34·57 atoms per cent. of silver on the one hand, and 62·6 atoms per cent. on the other. Micrographic examination confirmed the results obtained by the thermal investigation of the alloys. Magnesium-silver alloys are characterised by their hardness, which exceeds that of either of the components. The brittleness is greatest in those alloys approximating in composition to the definite compounds of the two metals. The alloys rich in magnesium are very brittle, easily oxidised, and decompose water more readily than pure magnesium; on exposure to the air, they disintegrate with production of a black powder.—A. S.

Aluminium-bismuth and aluminium-tin alloys. A. G. C. Gwyer. Z. anorg. Chem. 1906, **49**, 311—319.

ALUMINIUM and bismuth in the liquid state are mutually soluble only to a slight extent; the lowering of the melting-point of aluminium by addition of bismuth amounts to not more than about 5° C.

The gradual addition of tin to aluminium lowers the melting-point continuously, rapidly to 15 atoms per cent. of tin, more gradually to 55, then more rapidly again to 98 atoms per cent. of tin—a eutectic solidifying at 229° C.; beyond this the melting point rises to that of pure tin. No evidence of any compound of the two metals is furnished by the melting point curve.—J. T. D.

Aluminium bronze powders; Explosions of ——. Stockmeier. Chem.-Zeit., 1906, **30**, 580.

THE metal is pounded in stamp-mills, sorted according to size of grain, and is then polished in polishing mills. Very fine sorts are submitted to a rubbing treatment, after sifting, and before polishing, by grinding the metal dust with gum arabic solution. The explosions which occur in the sifting and polishing machines are dust explosions caused by accidental sparks in the machinery. Ordinary aluminium bronze powders do not flash when blown through a flame, but the finest sorts can be ignited in this manner, or even by a match. Another danger of explosions is that due to hydrogen evolved by the action of aluminium dust on water. A slight elevation of temperature in the process of washing out the gum may give rise to a sudden evolution of hydrogen. The author has established that the decomposition of water by

aluminium dust begins at 30° C., but does not take place at 20° C.; iced water is generally used for washing the metal. In cases of fire, when red-hot aluminium is quenched by water, large flames of burning hydrogen, or even explosions are produced. Since aluminium bronze in the form of fine dust normally contains about 2·3 per cent. of moisture, it has been suggested that explosions in the polishing machines may be due to the production of hydrogen by the decomposition of this moisture. The author has proved, however, that the production of hydrogen by the decomposition of the normal moisture of the metal never exceeds 4 per cent. of the theoretical quantity even under the most favourable conditions, and this quantity is not dangerous. Explosions have been greatly reduced of late years by the use of exhaustor fans, but two cases are on record where the breaking of a fan-blade has ignited the aluminium dust passing through the fan. Ignition by frictional electricity has been suggested as a possible cause of explosion, but no authenticated case is known. (See also this J., 1906, 430.)

—J. F. B.

Silicon chloride; Action of ——, on nickel. E. Vigouroux. Comptes rend., 1906, **142**, 1270—1271.

CONTINUING his researches, the author now describes the action of silicon chloride on nickel, the experiments being carried out on the plan employed previously in the case of iron and cobalt (see this J., 1905, 1308; 1906, 318), except that in the present instance the course of the reaction was more closely followed, and the successive products formed analysed separately. Two products were obtained, one containing 9·6 per cent. of silicon, corresponding with the formula Ni_4Si, and the other 19·3 per cent., corresponding with Ni_2Si. It is considered to be not at all improbable that at extremely high temperatures compounds still richer in silicon may be obtained.

—W. P. S.

Zinc-antimony alloys. S. F. Zemczuznyj. Z. anorg. Chem., 1906, **49**, 384—399.

THE author confirms, in general, the results obtained by Mönkemeyer (this J., 1905, 137). The compound, Zn_3Sb_2, does not form solid solutions either with zinc or with antimony. It crystallises in prisms, which can be easily obtained by piercing the skin which forms on the surface of the fused alloy, pouring off a portion of the molten material, and allowing it to cool slowly, when tolerably well-defined crystals are formed in the interior of the regulus. The compound is capable of existing in two modifications, the transformation from one to the other taking place, not at a constant temperature, but over the range 330°—358° C., according to the proportion of the compound present in the alloy in question, the higher temperature being the transformation point in the case of the pure compound. When free antimony and the compound, Zn_3Sb_2, are present together in an alloy, a condition of unstable equilibrium results; the crystals of the compound which first separate subsequently react with the antimony to form the compound, ZnSb, the reaction being accompanied by evolution of heat. The compound, ZnSb, decomposes on melting.—A. S.

Ferro-tungstens; Study of pure ——. E. Vigouroux. Comptes rend., 1906, **142**, 1197—1199.

THE alloys were prepared in crucibles of magnesia, by the alumino-thermal process, from pure oxide of iron and tungsten oxide, WO_3, obtained from pure ammonium tungstate by calcination, and reduction in hydrogen at a temperature below 400° C. Three perfectly homogeneous alloys were prepared, free from aluminium, and containing 2·30, 6·21, and 46·25 per cent. of tungsten respectively. The alloys were soft (they crushed easily under the hammer), slightly brittle, and granular or lamellar in structure, being less brittle and more granular as the percentage of iron became larger. They were attacked vigorously by hydrochloric acid, iron being dissolved, and also, eventually, a very small quantity of tungsten, which coloured the solution blue. *Aqua regia* attacked the alloys slowly, iron being dissolved, and tungstic acid precipitated, whereby the further action of the acid was hindered. By treating the alloys with dilute hydrochloric acid till nothing further was dissolved, the compound, Fe_3W_2, was left behind, in the form of brilliant plates having a metallic appearance. The compound has the sp. gr. 13·89 at 0° C., and is not appreciably magnetic. It is attacked vigorously by chlorine at 350° C., but is not acted upon by dry oxygen except at a bright red heat. It is not appreciably affected by solutions of hydrochloric and nitric acids, or by gaseous hydrochloric acid, and only slightly by *aqua regia* and sulphuric acid. For decomposing the compound, the best agent is potassium bisulphate, which attacks it rapidly at a dark red heat.—A. S.

Carbon-steel; Physico-chemical researches on ——. C. Benedicks. Jernkont. Ann., 1906, **60**, 107; Chem. Zeit., 1906, **30**, Rep. 184.

A NUMBER of the physical properties of steel are explained by the assumption that steel with over 0·5 per cent. of carbon consists of β-iron containing about 0·27 per cent. of hardening carbon, whereas iron and mild steel with less than that proportion consist of α-iron, the hardening carbon being regarded as concerned in the staining of ferrite by iodine tincture. The influence of silicon on the sp. gr., in conjunction with chemical tests, indicates the existence of a hitherto unknown light carbide, Fe_2C. It also appears that the transformation from the α- to the β- form is accompanied by a measurable contraction. The modulus of elasticity varies inversely with the carbon content; and the modulus is diminished to the same extent, or nearly so, by equivalent quantities of carbon, silicon, and nickel. With regard to the relation between the degree of hardness and the chemical composition, it is found that equivalent quantities of silicon and manganese have an equal effect, this being greater in the case of β-iron, but not so great as that of hardening carbon.

Electrical resistance.—Equiatomic solid solutions of the iron have the same resistance, and this applies approximately to the eleven different dissolved elements tried. The hardening carbon can be estimated from the resistance, which, in iron and mild steel, increases with the total carbon up to 0·15 per cent. of that element. Equivalent proportions of hardening carbon and manganese have the same effect in diminishing the intensity of magnetisation, and the diminution can be expressed by a formula.

Ferronite.—All the chemical, physical, and micrographical details tending to prove the existence of "ferronite" (a solid solution of β-iron with about 0·27 per cent. of carbon), are given, and this substance is considered to explain certain obscure phenomena.—C. S.

Copper-cadmium alloys. R. Sahmen. Z. anorg. Chem., 1906, **49**, 301—310.

COPPER and cadmium form two compounds, of formulæ Cu_2Cd and Cu_2Cd_3. From fused mixtures of the two metals containing 0—42 atoms per cent. of cadmium, copper crystallises out between 1084° and 552° C.; at the latter temperature long needles of the compound, Cu_2Cd, appear, and at 542° C. the rest of the mixture solidifies as a eutectic. Fused mixtures containing 42—45·4 atoms per cent. of cadmium deposit between 552° and 542° C. the same compound, Cu_2Cd; and the mixture containing 45·4 atoms per cent. solidifies eutectically at 542° C. Mixtures containing 45·4—60·0 atoms per cent. of cadmium deposit mixed crystals of the compounds, Cu_2Cd and Cu_2Cd_3, and those containing 60·0—97·97 atoms per cent., mixed crystals of the compound, Cu_2Cd_3 and cadmium. The mixture with 97·97 atoms per cent. of cadmium solidifies eutectically at 314° C., and mixtures richer in cadmium than this deposit cadmium from 314° to 321°·7 C.

—J. T. D.

Cæsium; Direct oxidation of ——. Properties of cæsium peroxide. E. Rengade. VII., page 637.

Mineral production of Southern Rhodesia. Bd. of Tr. J., June 28, 1906. [T.R.]

THE report for the year ended March 31st last, of the Rhodesia Chamber of Mines states that the output of gold from Southern Rhodesia and Tati for that year was declared at 438,893 oz. 3·49 dwts., valued at £1,599,195, being an increase of 129,376 oz. in weight and £478,667 in

value as compared with the year ended 31st March, 1905. The output of silver amounted to 83,996·27 oz., valued at £9,390; that of lead to 550·98 tons, valued at £6,232; and that of diamonds from the Somabula area to 1,161 carats, valued at £4,208. The yield of coal from the Wankie Colliery amounted to 111,105 tons; the sales during the year realised £62,285.

Metal and Mineral Production of New South Wales. Bd. of Tr. J., June 28, 1906. [T.R.]

From the Annual Report of the New South Wales Department of Mines for 1905, it appears that the metals and minerals produced in New South Wales during that year were valued at £7,017,940, as compared with a value of £6,391,764 in 1904. The quantities and values of the chief metals and minerals produced are shown in the following table:—

	1904.		1905.	
	Quantity.	Value.	Quantity.	Value.
		£		£
Coal ..... Tons	6,019,809	1,994,952	6,632,138	2,003,461

*Exclusive of copper produced from ore from the other States of the Commonwealth.
†Made from scrap, no ore being used.
‡Exclusive of tin refined from imported ores.

Mineral production of Carthagena (Spain). For. Off. Ann. Series No. 3644. [T.R.]

446,035 tons of iron and manganiferous iron ores were shipped in 1905, of which the United Kingdom took 297,645 tons, being 131,010 tons more than in 1904.

Shipments of Cehegin (or Calasparra) magnetic ore have greatly increased. Although this ore meets with little acceptance in the United Kingdom, there appears to be no difficulty in disposing of all that is mined to other countries, chiefly Germany.

The shipments of silver and soft lead in 1905 amounted to 32,865 tons and 23,900 tons respectively. The export of silver-lead was 2,486 tons more than in 1904, and of soft lead 1,464 tons more. The increase in exports may be attributed chiefly to the higher prices of lead and zinc which permitted poorer lead mines to be worked, and caused the increased mining of blende, amongst which lead ore, to some extent, is usually found, and from which it is separated and sold to local smelters.

The quantity of silver exported during the year was 33,955 kilos., about 1,056,102 oz. troy, all to France. The quantity of zinc ore shipped was 88,430 tons, of which 56,125 tons went to Belgium. Of this quantity about 16,000 tons were calamine and the rest blende. These figures show a decrease of 4,206 tons as compared with 1904, and are about equal to those of 1903, but the above-named quantity exported in 1905 does not represent the quantity mined, and placed in deposit ready for shipment, as at the end of the year the stocks in this position were about 20,000 tons, and had not been shipped, principally because the different works which consume the ore were so blocked up that they postponed taking delivery. A notable feature is that Germany has taken about 11,000 tons more, while Belgium has taken nearly 15,000 tons less.

Shipments of iron pyrites were only 95 tons less than in 1904 (2455 tons).

The export of ochre for 1905 was better by 590 tons than in 1904, amounting to 1150 tons, of which the United Kingdom took 873 tons. Sulphur is again being shipped from mines in the interior, 895 tons having been sent off during the year to the United Kingdom. During the year only 80 tons of lead ore have been exported, 10 tons to the United Kingdom and 70 tons to France, thus going back to the small quantities bought for pottery purposes only. The experiment made in 1904 by an inland miner to export this ore instead of selling it to local smelters has not encouraged him to repeat shipments. 344 tons of copper ore were shipped to France, and 52 tons to the United Kingdom, total 396 tons, being about 200 tons less than in 1904, and 566 tons less than 1903. Only 74 tons of copper matte were exported, of which 16 tons went to the United Kingdom.

English Patents.

Steel; Treatment of ——. W. Taylor, Leicester, and F. J. Mudford, London. Eng. Pat. 15,809, August 2, 1905.

The change in the magnetic properties of the steel at the critical temperature is used to indicate that the proper quenching temperature has been reached. There are many ways in which the invention may be carried into effect, as, for example, by making the mass of steel part of a magnetic circuit in inductive relation with a circuit which includes a telephonic receiver; or the tractive or directive force of the steel may be utilised to displace a magnetic indicator, and this displacement may actuate a secondary indicator such as an electric bell, but the invention is not confined to the specific means herein referred to.—J. H. C.

Furnaces for roasting, &c.; Rabble-shafts and arms for ——. A. V. Leggo, Ballarat, Australia. Eng. Pat. 17,370A, Aug. 28th, 1905.

Various contrivances are provided to prevent leakage where water-cooled arms form junctions with the shafts, and also for attaching tines or teeth to the arms, whereby any tooth may be removed without disturbing the others.
—J. H. C.

United States Patents.

Ores; Method of melting primary baths for dissolving ——. R. Baggaley, Pittsburg, Pa., and C. M. Allen, Lo Lo, Mont. U.S. Pat. 822,712, June 5, 1906.

The "primary bath" is obtained by melting an ore of "high fuel value," with the aid of a large volume of blast, and producing from the ore a matte which "approximates as closely to the original combinations of sulphur, iron, copper, silver, gold, and the like in the original ore as is consistent with the removal of the gangue."—A.S.

Sulphide ores; Method of utilising as fuel the volatile portions of ——. R. Baggaley, Pittsburg, Pa., C. M. Allen, Lo Lo, Mont., and E. W. Lindquist, Chicago, Ill. U.S. Pat. 822,713, June 5, 1906.

The ore is introduced into a body of molten matte into which air is blown, and while the ore is floating in the matte, a supplementary blast of air is introduced above the molten matte, and at the place of contact of the floating ore therewith. The volume of air introduced is regulated so that all escaping sulphur is oxidised, but the resulting gases are not injuriously cooled.—A. S.

Ores and tailings; Apparatus for treatment of ——. A. Soderling, Bodie, Cal. U.S. Pat. 822,398, June 5, 1906.

The patent relates to the treatment of tailings or slimes preliminary to cyaniding. The ore or tailing is crushed between rollers, and fed by a jet of water into the upper end of an inclined trough with a riffle-bottom. A weak solution of solvent acids or acid salts is supplied from a tank, and at the lower end of the trough there are settling reservoirs for sands and for slimes, and a reservoir for base metal solutions.—A. S.

Copper; Process of hardening ——. C. R. Plumer, Assignor to Renstrom Tempered Copper Co., Seattle, Wash. U.S. Pat. 822,299, June 5, 1906.

Copper or a copper alloy is melted and treated with a hardening agent such as "copper sulphate," and a chilling agent such as "potassium bichromate." The mass is stirred until it becomes stiff, and is then reheated, and allowed to cool.—A. S.

[*Copper and nickel*] *Ores; Process of treating* ——. J. O. Handy, Pittsburg, Pa. U.S. Pat. 821,637, May 29, 1906.

Arseniferous cobalt and nickel ores containing silver are ground, sifted to 80-mesh size, and the fine ore is fused with sodium bisulphate to expel arsenic, which is recovered. The product is leached, and from the solution the silver is reduced and precipitated by means of a fresh portion of the arsenide ore, the iron and arsenic are removed, the cobalt and nickel are separated by fractional precipitation with hypochlorite, and sodium sulphate is recovered by evaporation and crystallisation. In the separation of the cobalt and nickel, the cobalt is first precipitated by adding slightly more than the necessary quantity of hypochlorite, and the nickel is dissolved out of the precipitate by a portion of the solution from which the iron and arsenic have been removed.—A. S.

Metallic flakes or scales; Process of making ——. T. A. Edison, Llewellyn Park, N.J., Assignor to Edison Storage Battery Co., West Orange, N.J. U.S. Pat. 821,627, May 29, 1906.

This invention relates to a process of making flakes or scales of cobalt, or of nickel and cobalt, and consists in subliming cobalt chloride, or mixed nickel and cobalt chlorides, in order to deposit the same in scales or crystalline flakes. The latter are then converted into hydroxides of the metals, and the hydroxides finally reduced to the metallic state.—B. N.

Conducting-films [*Cobalt*]; *Process for making* ——. T. A. Edison, Llewellyn Park, N.J., Assignor to Edison Storage Battery Co., West Orange, N.J. U.S. Pat. 821,628, May 29, 1906.

A sulphur compound of a metal, such as cobalt, is fused with an alkali sulphide, and the fused mass allowed to cool, so as to result in the crystallisation of the compound in thin scales or films. These are then screened in order to separate crystals not in the form of scales, and washed to eliminate alkali sulphides. The scales are roasted to oxidise the same, and the oxidised scales or films are reduced in an atmosphere of hydrogen to the metallic state.—B. N.

Steel; Manufacture of ——, *from phosphoritic iron.* J. Reese, Sharon Hill, Pa., Assignor to The Steel Patents Co., Pa. U.S. Pat. 821,744, May 29, 1906.

The molten metal is first de-siliconised and decarburised in a Bessemer convertor, and is then transferred to a basic-lined open-hearth furnace, wherein it is subjected to a bath of basic materials containing so much calcium phosphate that a slag is produced containing not less than 15 and not more than 22 per cent. of phosphoric acid.—A. S.

Nodulising ores, &c. C. Dellwik, London, Assignor to J. E. Goldschmid, Frankfort-on-Maine, Germany. U.S. Pat. 822,929, June 12, 1906.

See Fr. Pat. 360,576 of 1905; this J., 1906, 543.—T. F. B.

French Patents.

Furnaces; Impts. in metallurgical and other ——. Soc. anon. des Gazogènes sous Pression. Fr. Pat. 362,268, Jan. 9, 1906.

The mixture of air and gas to be used as fuel enters the furnace by way of a helical conduit or pipe constructed of a suitable metal, which is disposed in the masonry, and is heated by the products of combustion from the heating chamber of the furnace.—A. S.

Iron; Process for the desulphurisation of substances containing compounds of ——, *and for forming the same into lumps.* T. C. King. Fr. Pat. 362,145, Jan. 3, 1906.

The process is intended especially for converting burnt pyrites and flue dust into a form suitable for use in blast-furnaces or Siemens-Martin furnaces. The material, containing a certain percentage of moisture, is heated gradually in a long, cylindrical, rotating furnace, first to a temperature (646°—815° C.) high enough to expel the sulphur, and then to a temperature above 1090° C., to cause the material to agglomerate. It is stated that the material is thus obtained in the form of lumps of irregular size and shape, practically free from sulphur, and suitable for direct employment in blast-furnaces or Siemens-Martin furnaces.—A. S.

Steel for rails of railways and tramways; Manufacture of ——. G. P. Sandberg. Fr. Pat. 362,240, Jan. 8, 1906. Under Int. Conv., April 11, 1905.

See Eng. Pat. 7698 of 1905; this J., 1905, 1309.—T. F. B.

German Patent.

Iron and mild steel; Process for the cementation and hardening of articles of ——. G. Reminger. Ger. Pat. 167,034, June 23, 1904.

The process consists in heating the articles to redness, and then subjecting them to the action of a solution of a formate, *e.g.*, ammonium formate. It is claimed that by the use of formates, a uniform and strong carburisation is effected, that polished surfaces remain quite smooth, and that the use of alkali cyanides is avoided. The degree of carburisation can be controlled by varying the concentration of the formate solution.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(*Continued from page* 595.)

(*A.*)—ELECTRO-CHEMISTRY.

Alcoholates and alkyl-carbonic acid esters; Electrolytic preparation of ——. B. Szilard. Z. Elektrochem, 1906, **12**, 393-395.

By the electrolysis of alkali alcoholates with platinum electrodes, the corresponding alkyl-carbonic acid esters are formed; for example, sodium methylate yields sodium-methyl carbonate, and sodium ethylate sodium-ethyl carbonate. The best yields are obtained with a 4 per cent. solution of the alcoholate in the perfectly anhydrous alcohol, and with a current-density as high as is possible without causing evolution of gas at the anode. If a base metal anode be used, there is produced the alcoholate of that metal if the current-density be low, or the alkyl-carbonic acid ester of the metal if the current-density be high, whilst with medium strengths of current, mixtures of the two compounds are produced. The formation of the alkyl-carbonic acid esters is due to a secondary decomposition of the alcoholates produced first.—A. S.

English Patents.

Secondary or storage batteries. A. J. Boult, London. From E. V. Stebbins, Philadelphia, Pa. Eng. Pat. 26,876, Dec. 23, 1905.

The lead oxide for the negative plate of a storage battery

is mixed with about 5 per cent. of an insoluble, finely divided sulphate, *e.g.*, barium sulphate precipitated from a cold solution.—A. G. L.

White lead; [Electrolytic] Manufacture of ——, and mixtures of the same with oxides of lead. W. P. Thompson. From R. Goldschmidt and E. Polzininsz. Eng. Pat. 11,347, May 30, 1905. XIII*A*., page 644.

UNITED STATES PATENTS.

Storage batteries; Process of treating alkaline ——. T. A. Edison, Llewellyn Park, N.J., Assignor to Edison Storage Battery Co., West Orange, N.J. U.S. Pat. 821,625, May 29, 1906.

THIS invention relates to a process of eliminating soluble impurities from alkaline storage batteries, in which active masses of oxygen compounds of nickel and iron are used, and in which a conducting receptacle of an insoluble metal is employed. The receptacle is insulated to reduce the dissipation of heat, and the two electrodes are connected in circuit as cathodes with the conducting receptacle in alkaline solution. A reverse current is then passed through the battery, so as to heat the solution, and generate hydrogen gas in the active masses. The impurities are thus forced out into the solution, and this is finally poured off.—B. N.

Cell; Electrolytic ——. G. A. Gabriel, Assignor to Bleach and Caustic Process Co., New York. U.S. Pat. 822,109, May 29, 1906.

THIS invention relates to an electrolytic cell containing a porous diaphragm with a perforated vertical cathode in contact with one side of the diaphragm, and an anode having an active face adjacent to the opposite side of the diaphragm, together with a second diaphragm between the first diaphragm and the anode, with gauze embedded in it. Insulating material limits the inner exposed surface of the diaphragm to approximately the size of the active face, but the active area of the cathode is greater than the inner exposed surface of the diaphragm. The anode is continuous, with horizontal and vertical passages in it for the circulation of the electrolyte, and the cathodes are of substantially similar outline. The liquid which percolates through the diaphragm is conveyed away by downwardly-inclined projections, or liquid-conduits, extending from the face of the cathode which is out of contact with the diaphragm, thus draining the entire face by gravity. A plate engages with the liquid-conduits, and a means is provided for forcing the plate towards the cathode and diaphragm. A perforated draining plate connects the conduits at their lower ends. An exterior vertical transparent conduit communicates directly with the interior of the anode chamber at three points, one above the surface of the electrolyte, one slightly below the surface, and one near the bottom of the anode chamber, thus allowing of circulation of the electrolyte. An adjustable overflow pipe is located within the conduit, and a gas-discharging tube is connected with the top of the conduit.—B. N.

Organic substances; [Electrolytic] process of treating [oxidising and reducing] ——, in presence of vanadium compounds. E. Oppermann, Assignor to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst-on-the-Maine, Germany. U.S. Pat. 823,435, June 12, 1906.

SEE Fr. Pat. 345,701 of 1904; this J., 1905, 33.—T. F. B.

Electric arcs; Production of stable ——, of large dimensions. Badische Anilin und Soda Fabrik. First Addition, dated Dec. 9, 1905 (under Int. Conv., Nov. 1 and 14, 1905) to Fr. Pat. 357,358 of Aug. 30, 1905 (this J., 1906, 79).

INSTEAD of passing the gas along the whole length of the electrode as in the main patent, it may be introduced into the tube only, beyond the end of the central electrode. Since the electrode is corroded somewhat by constant use, arrangements are made for its renewal without interruption of the process. The hot gases, leaving the reaction chamber, are employed for preheating the gases to be subjected to the action of the arc, or they may be used for evaporating solutions obtained in the course of the process. Forms of apparatus are described suitable for carrying these modifications into effect.—R. S. H.

FRENCH PATENT.

Battery; Electric ——, with aluminium chloride as exciting and depolarising liquid. H. Femerling and W. Pörscke. Fr. Pat. 362,280, Jan. 9, 1906.

A MIXTURE of carbon, manganese peroxide, aluminium chloride, and water is made, and compressed as usual around a carbon rod or into a hollow cylinder of carbon. The mass is surrounded by cloth, and placed in a receptacle of zinc or other suitable metal, containing a solution of aluminium chloride, or a pasty mass consisting of a double hydrous silicate of aluminium and magnesium. —B. N.

Chromic acid; Electrolytic regeneration of ——, in solutions of chromium salts. M. Le Blanc, Fr. Pat. 362,195, Jan. 5, 1906. Under Int. Conv., March 13, 1905

THE anode and cathode chambers are separated by partitions which do not reach quite to the bottom of the vat. The solution of chromic oxide is introduced in such a manner that the cathode liquid retains a suitable degree of acidity. It is advantageous to allow the solution of chromic oxide to first come in contact with those portions of the anode where the current density is highest, and subsequently with those where the current density is lower.—R. S. H.

(*B.*)—ELECTRO-METALLURGY.

Zinc; Electrolytic deposition of ——, using a rotating electrode. J. S. Price and G. H. B. Judge. Faraday Soc. Trans., June 12, 1906. [Advance proof.]

THE authors have studied the quantitative determination of zinc in zinc sulphate solutions, using the rotating electrodes recommended by Perkin (this J., 1903, 1065, Fig. 3). The solution is contained in a tap-funnel of about 100 c.c. capacity. Quantitative results are obtained if the solution be kept cool, even when the zinc sulphate solution is initially slightly acid. The addition of sodium acetate and sodium sulphate was tried, and in the latter case good results were obtained. A modified form of Kollock and Smith's apparatus (this J., 1905, 1127) is also described, in which a mercury cathode and rotating anode are employed. Here again a cylindrical vessel provided with a tap is used to contain the electrolyte, and after the completion of the experiment, the zinc amalgam can be run off through the tap, and subsequently weighed.—R. S. H.

UNITED STATES PATENTS.

Metallic films or flakes; Process of making —— [Electrolytically]. T. A. Edison, Llewellyn Park, N.J., Assignor to Edison Storage Battery Co., West Orange, N.J. U.S. Pat. 821 626, May 29, 1906.

A THIN film of a soluble metal, such as zinc, is deposited on a suitable cathode, and an insoluble metallic film of metallic cobalt or cobalt alloy is deposited over this. The plated cathode is subjected to the action of dilute acid, which dissolves the zinc, and the liberated hydrogen separates and detaches the insoluble film. The latter is finally annealed in an atmosphere of hydrogen.—B. N.

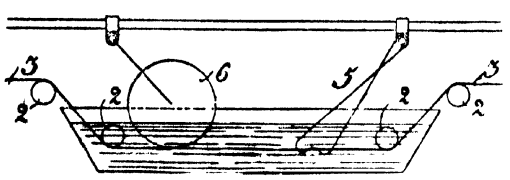
Steel containing titanium; Production of ——. A. J. Rossi, New York, Assignor to J. MacNaughton, Tahawus, N.Y., and P. C. Peck, New York. U.S. Pat. 822,305, June 5, 1906.

STEEL containing more than 1 and less than 5 per cent. of titanium is obtained by fusing molten cast-iron containing a definite percentage of carbon in an electric furnace, and treating it with a quantity of titanium oxide sufficient to decarburise the metal to the desired extent. By regulating the current, a high temperature is then maintained sufficient to effect the decarburisation, and to cause the reduced metallic titanium to be combined with the steel.—A. S.

Furnace; [Electric] Metallurgical ——. I. L. Roberts, Assignor to J. T. Morehead, New York. U.S. Pat. 821,830, May 29, 1906.

THE furnace consists of a receptacle or jacket, with a lining of heat-insulating material, and within this a chamber having refractory walls. Inside the chamber is a conducting vessel, with masses of resistance material on opposite sides, in contact with the walls of the chamber, but not in contact with each other. Electrodes are connected with the masses of resistance material.—B.N.

Furnace; Continuous magnetic ——. H. C. Shaw, Glenshaw, Pa. U.S. Pat. 821,752, May 29, 1906.



A HOLLOW screw conveyor is disposed within the heating chamber of the furnace, and is magnetised, and rotated, whereby magnetic material in the chamber is caused to travel along the screw. A cooling fluid is supplied to the interior of the screw. Within the screw, also, a grooved rod is caused to rotate, to prevent deposition of foreign matter.—A. S.

Metallic surfaces; [Electrolytic] Process of cleaning ——. T. A. Edison, Llewellyn Park, N.J. U.S. Pat. 821,622, May 29, 1906.

SEE Eng. Pat. 26,947 of 1904; this J., 1905, 201.—T. F. B.

FRENCH PATENT.

Deposition of metals; Arrangements suitable for the ——, *by electrolysis.* A. Schmutz. Fr. Pat. 362,182, Jan. 5, 1906.

IN order to facilitate the employment of high current-density in the electro-deposition of metals upon wires, &c., a displaceable arrangement is employed to lead the current to the material which is being plated. In the figure the method is illustrated in two ways; the wire, 3, passes over rollers. 2, which may be of insulating material. The current is conducted independently of these rollers by movable contacts which may either be of a rolling nature as at 6, or sliding, as at 5.—R. S. H.

(*Continued from page* 597.)

(*A.*)—PIGMENTS, PAINTS.

ENGLISH PATENTS.

White lead; [Electrolytic] Manufacture of ——, *and of mixtures of the same with oxides of lead.* W. P. Thompson, London. From R. Goldschmidt and E. Polzniusz, Brussels. Eng. Pat. 11,347, May 30, 1905.

A SOLUTION containing about 1 part of sodium acetate to about 9 parts of sodium carbonate, is electrolysed in a suitable elevated vessel, in which the anodes consist of thick, and the cathodes, alternately with these, of relatively thin plates of lead. The bottom of the bath has a valved aperture, discharging into a vessel beneath, the latter being provided at the top with a filter or strainer. The filtered solution is forced by a pump into a closed vessel, heated from below, into which carbon dioxide is admitted under pressure. The electrolysis of the solution induces formation of lead acetate, which, in presence of the sodium carbonate, passes into lead carbonate. As the white lead formed is removed, and carbon dioxide is supplied to the filtrate under pressure, the sodium carbonate that has suffered decomposition is reformed. An upright tube, passing into the closed vessel, and continued so as to discharge, under pressure, into the electrolytic bath above, renders the process continuous, the proportion of acetate present remaining constant. By varying the temperature and the degree of the carbon dioxide impregnation, mixtures of white lead with lead oxides may be obtained. (Reference is directed to Eng. Pats. 14,801, of 1895, 19,179 of 1897, and 2382 of 1899; this J., 1895, 975; 1898, 163; and 1899, 502.)—E. S.

Lakes [from azo dyestuffs]; Manufacture of colouring matter ——. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 19,100, Sept. 21, 1905.

FRENCH PATENT.

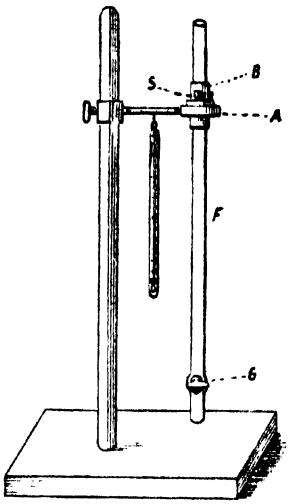
Lakes [from azo dyestuffs]; Production of red ——, *fast to light.* L. Cassella und Co. Fr. Pat. 361,313, March 31, 1905.

LAKES are prepared in the usual manner from the azo dyestuff from diazotised *p*-chloro-aniline and β-naphthol-disulphonic acid R. The red lakes thus obtained are said to be considerably faster to light than those derived from *o*- or *m*-chloro-aniline.—T. F. B.

(*B.*)—RESINS, VARNISHES

Pine resin (Pinus abies L.); Chemical investigation of the acids in ——. P. Klason and J. Koehler. J. prakt. Chem., 1906, **73**, 337—358.

THE authors review previous literature on the subject of resin acids, and state that in many cases the conclusions drawn by different workers are vitiated on account of neglect to take into account the fact that these acids are autoxidisable (compare Fahrion, this J., 1902, 127). The



authors have observed that in the winter and spring (from January to April in the neighbourhood of Stockholm) a perfectly white and crystalline resin, bearing a striking resemblance to sugar, occurs sparingly under the bark of pine and fir trees. They name this product "winter resin" to distinguish it from ordinary pine resin, or "summer resin." It consists of a mixture of resin acids of the type, $C_{20}H_{30}O_2$, melting at about 140° C., and having a varying lævo-rotation, the highest value observed being $[\alpha]_D = -150{\cdot}46°$. On recrystallisation from alcohol, lamellar crystals of higher rotatory power and melting point are obtained. The mixture of acids is very sensitive to heat, the rotatory power being strongly diminished. "Summer resin" consists of a mixture of resin acids and oxidation products of the same, the latter usually amounting to at least 50 per cent. of the total. The oxidation products are insoluble in petroleum spirit, which dissolves the resin acids. On distilling *in vacuo* the resin acids obtained by extracting "summer resin" with petroleum spirit, acids isomeric with those present in "winter resin," but more stable, and having a lower rotatory power, are obtained. They are probably produced from the former by a stereometrical transformation brought about by the action of heat. The authors propose to name these acids, *colophonic acids*, and the more active acids present in the original resin and in "winter resin," *sapinic acids*. The name colophonic acids is proposed to distinguish the products from the abietic acids of Tschirch and Studer (this J., 1903, 1250) which the authors do not regard as chemical individuals. The acids previously obtained by different workers from pine and firs resins, and from American colophony, *e.g.*, abietic, sylvic, and pinic acids, and perhaps also colopholic acid, are all probably mixtures of sapinic and colophonic acids.

For the isolation of the colophonic acids, ordinary crude pine resin from which the turpentine oil had been removed by distillation with steam, was repeatedly extracted with petroleum spirit, the solvent was removed from the extract by distillation, and the residue was subjected to fractional distillation *in vacuo*. From the light yellow resin obtained as distillate, the resin acids were separated by crystallisation from petroleum spirit, followed by washing of the crystals with the solvent. From 2150 grms. of crude resin, there were obtained 150 grms. of crude oil of turpentine, 750 grms. of substances insoluble in petroleum spirit (700 grms. of oxidised resin acids and 50 grms. of impurities), and grms. of crude resin acids (sapinic acids). The la[illegible]on distillation yielded 400 grms. of residue and tions us[illegible] of distillate, from which 145 grms. of crystallised and caste[illegible] acids were isolated. The mixture of colo- to the acid[illegible]s, $C_{20}H_{30}O_2$, melted at 168°—172° C., and had for the cas[illegible] rotation $[\alpha]_D = +28{\cdot}14°$. It can be roughly [illegible] to its two components by fractional crystalli- [illegible] [illegible]cid being more readily soluble in petroleum spir[illegible] acetic acid, methyl and ethyl alcohols, ether, [illegible]cetaldehyde. The ammonium, calcium and barium salts were prepared, and it was found that the best separation of the two acids was obtained by fractional crystallisation of the ammonium salts from alcohol, but the acids were not obtained quite pure, owing to oxidation. The most reliable numbers for the melting point and optical rotation of the two acids are as follows:—α-colophonic acid, m.pt., 198°—199° C.; $[\alpha]_D = -59{\cdot}41°$; β-colophonic acid, m.pt., 168°—173° C.; $[\alpha]_D = +52{\cdot}2°$. The authors' β-colophonic acid is probably identical with the amorphous abietic acid of Easterfield and Bagley (this J., 1904, 989).

—A. S.

Varnishes; Viscosimeter for ——. E. Valenta. Chem. Zeit, 1906, **30**, 583—584.

THE measurement of the rate of flow through an orifice having proved unsatisfactory for determining the viscosity of linseed oil varnishes, the author has devised the simple "ball-fall" apparatus, illustrated in the figure. It consists of a glass tube, F, 63 cm. in length, and 13 m.m. inside diameter. The top of the tube is open, whilst a glass cock, G, 10—11 mm. in bore, is attached to the lower end. The collar, B, is clamped on the upper part of the tube, and carries two

steel knife-edges, S, which are supported on the ring, A, in such a manner that the tube always hangs in a vertical position. The tube is filled with the fluid, and a silver ball, 9 mm. in diameter, is allowed to fall from the top to the bottom, the time being accurately measured. When the ball reaches the bottom, the lower orifice is closed by the thumb, the cock is opened, and the ball passes through, being removed after closing the cock. The mean of ten determinations is taken, and the result is compared with that obtained with a standard castor oil.—J. F. B.

English Patent.

Linoleum mass and the like; Process for the manipulation of granular ——. E. C. R. Marks, London. From R. Holtkott, Bedburg-on-Rhine, Germany. Eng. Pat. 2436, Jan. 31, 1906.

THE difficulty of manipulating the linoleum mass due to its stickiness is overcome by powdering it with a fine vegetable or animal flour, such as rice starch, potato flour, or bone flour, prior to its introduction into the moulds. The flexibility of the linoleum is also increased by this addition.—C. A. M.

French Patent.

Resinous materials and their derivatives; Employment of superheated steam in the preparation and distillation of ——. Soc. Guignard et Lestandie. Fr. Pat. 362,264, Jan. 9, 1906.

SUPERHEATED steam is used in the distillation of resinous materials, instead of distilling with steam under pressure or distillation with a naked flame.—B. N.

(*C.*)—INDIA-RUBBER, Etc.

India-rubber containing notable amounts of resin; Vulcanisation of ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 918.

EIGHTEEN varieties of raw india-rubber, containing from 1·4 to 12·2 per cent. of resin, were vulcanised with 10 per cent. of sulphur for one hour at 145° C., under a pressure of 3—4 atmospheres, and the products tested mechanically. None of the rubbers containing upward of 7 per cent. of resin were completely vulcanised by this treatment, whilst several of those containing less were decidedly under-vulcanised. Mozambique, Massai balls, Adeli balls, Soudan twists, and Lewa, all of which are highly resinous, showed remarkably high elasticity and strength, though only the last-named was fully vulcanised.

The experiments, so far from indicating any connection between resin-content and behaviour under vulcanisation, prove that the nature and origin of the rubber are the paramount factors in this respect.—W. A. C.

Balata; Vulcanisation of ——. R. Ditmar. Gummi-Zeit., 1906, **20**, 893.

Washed and dried balata was vulcanised at 145° C., under a pressure of 4—5 atmospheres, with rising proportions of sulphur, and the products tested mechanically. With 50 minutes' vulcanisation the maximum of strength and extensibility was attained at 35—40 per cent. of sulphur; these specimens, however, were considered under-vulcanised. On vulcanising fully for 1½ hours, the extensibility reached a maximum at 40—45 per cent. of sulphur, whilst the breaking strains were throughout considerably less than those of the first series.—W. A. C.

Gutta-percha of Palaquium Treubi; Certain principles of the ——. E. Jungfleisch and H. Leroux. Comptes rend., 1906, **142**, 1218—1221.

When the gutta hydrocarbon is precipitated from the toluene extract of the leaves of *Palaquium Treubi* by means of boiling alcohol, a substance remains in solution to which the author gives the name of *paltreubin*. The liquors are evaporated to dryness, and waxy impurities are extracted by boiling alcohol; the paltreubin is then recrystallised from petroleum benzine until it has a constant melting point of 260° C. It crystallises in small, colourless, silky needles which sublime in the form of prisms; it dissolves best in benzine or toluene. Analysis indicates the formula $C_{30}H_{50}O$, isomeric with the amyrins obtained by Vesterberg from elemi. When heated in sealed tubes at 175° C. with acetic anhydride for 24 hours, paltreubin is completely converted into two acetates, *α* and *β*, melting respectively at 235° and 290° C. These acetates yield on saponification *α-paltreubyl alcohol* m.pt. 190° C., and *β-paltreubyl alcohol*, m.pt. 295° C. The *α*-alcohol and its acetate possess the same melting points as *β*-amyrin and its acetate, but are optically inactive. The *β*-alcohol is identical with a substance which has been isolated from the leaves of *P. gutta* and *P. borneense*. Paltreubin, which is not a mixture, is therefore regarded as an alcohol derived from a tri-terpene $(C_{10}H_{16})_3$; it undergoes isomeric change in two directions when acetylated.—J. F. B.

United States Patents.

Rubber; Machine for washing ——. F. C. Hood, Brookline, Mass. U.S. Pat. 821,716, May 29, 1906.

The machine comprises a tank in which is a pair of co-acting rollers mounted side by side in the same horizontal plane. The rubber to be washed is fed between the rollers from a tilting hopper, and washing liquid is introduced at the front of the tank, where the washed rubber is removed. The tank has two outlets, one at the bottom for the heavier impurities, and another at the top for floating matter; washing liquid is supplied in excess of that which can escape by the lower outlet. When the rubber emerges after its first passage between the rollers, it is automatically carried back, and passed through a second time. Means are provided for varying the temperature of the washing liquid in the tank.—A. S.

Rubber; Process of purifying ——. F. C. Hood, Brookline, Mass. U.S. Pat. 821,717, May 29, 1906.

The rubber is compressed or shredded between two rollers submerged in a washing liquid, and then passes through a further quantity of liquid before emerging from the containing tank. The current of liquid is utilised for returning the rubber issuing from the rollers for a second passage between them. The heavier impurities are removed through an outlet in the bottom of the tank, and the lighter impurities by means of an overflow outlet. (See preceding abstract.)—A. S.

Gum [Rubber manufacture]; Process of treating ——. A. P. Eves, Akron, Ohio. U.S. Pat. 821,934, May 29, 1906.

The patent relates to a method of refining gum, used in the manufacture of rubber. The gum is kept in a state of agitation, and exposed to the action of heated solvent (alcoholic) vapours, passed upwards, through and around it. The vapours are led into a condenser, and the condensed solvent is allowed to descend, through the rising vapour, on to the gum, thus utilising the heat of the vapour, and freeing the gum from deleterious substances. —C. S.

French Patent.

Caoutchouc; Process for the utilisation of waste —— Soc. Michelin et Cie. Fr. Pat 361,300, March 30, 1905.

The vulcanised caoutchouc in the form of fine powder is re-agglomerated by the influence of great pressure in moulds which are suitably heated, without treatment by the usual processes of manufacture. The internal section of the mould is such that the powder suffers the least possible lateral displacement during the compression. The final form of the piece may be obtained by a single stroke in the moulding, or by the reheating of a piece which has been first brought to a shape approaching as nearly as possible the final shape.—B. N.

German Patents.

Gutta-percha and balata; Process for obtaining —— from the leaves and wood of plants containing these substances. F. Frank and E. Markwald. Ger. Pat. 165,997, Dec. 10, 1903.

The leaves, &c., are heated under moderate pressure with dilute solutions of alkalis or alkali carbonates, until the melted gutta-percha or balata collects on the surface of the lye, from which it is recovered by extraction with a suitable solvent.—A. S.

Rubber, vulcanised, and ebonite; Process for the regeneration of ——. B. Roux. Ger. Pat. 166,639, March 16, 1904.

The rubber or ebonite, in small pieces, is mixed with sulphur, and subjected to a pressure of 100—500 atmospheres at a temperature of 150°—200° C.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

(*Continued from page 598.*)

Tanning material analysis. H. R. Procter. Colle[illegible] 1906, 173—179.

The author deals generally with the analysis [illegible] materials, and raises some points which sh[illegible] opinion be discussed at the coming Conferenc[illegible] Chemists at Prague. Whilst in the present [illegible] sampling and preparing materials for analy[illegible]s but little need for changes, some better pr[illegible]tion appears to be required. The filtration and t[illegible]mina-tion of so-called "insolubles" as now perform[illegible] require reform. Certain extracts, especially quebracho extracts, give persistently turbid filtrates with the candle-filter method, and the analytical results naturally vary in a marked manner from those obtained by the filter-paper-kaolin method. The greater part of the "insolubles" seems to consist of difficultly soluble tannins, and as it nearly always happens that extracts are perfectly clear at 100° C. whatever amount of insoluble matter they may give at 15° C., it is obviously merely a matter of temperature and dilution as to what percentage of the extract will prove insoluble in the tannery. With respect to the detannisation of solutions, and the determination of non-tannins, improvement is urgently needed. At present, chromed, the hide-powder offers the best solution of the difficulty, but to be satisfactory the hide-powder must not contain soluble matter, should absorb all true tannins rapidly and completely, and must not absorb acids and other matters which are not tannins. To comply with the first requirement the powder must be thoroughly chromed, and the chromium salts present must be in a sufficiently basic condition to suffer no further hydrolysis by the action of water or organic acids. Any good chromed hide-powder will absorb tannins rapidly, whether

it be lightly or fully chromed. The absorption of non-tannin matter by the hide-powder is a subject presenting many difficulties. The author considers that improvements in methods of analysis in this direction will lie in the splitting up into its various constituents of the total matter absorbed by hide-powder from tanning solutions. —W. P. S.

ENGLISH PATENT.

Glue; Process for the manufacture of ——. W. Sadikoff, St. Petersburg. Eng. Pat. 4570, Feb. 24, 1906.

SEE Fr. Pat. 358,859 of 1905; this J., 1906, 327.—T. F. B.

UNITED STATES PATENT.

Casein solution, and method of producing same. H. V. Dunham, Bellows Falls, Vt., Assignor to Casein Co. of America, New Jersey. U.S. Pat. 821,620, May 29, 1906.

THE casein is dissolved in a mixture of alcohol and an alkali hydroxide soluble in alcohol, the solution being then neutralised, and treated with formaldehyde. C. S.

FRENCH PATENTS.

Tanning skins and mordanting tissues; Substance for use in ——. O. H. Nowak, E. N. Eaton, and J. M. McVean. Fr. Pat. 360,854, Dec. 22, 1905.

A "SUBSTANCE," suitable for use in the tannage of skins and mordanting of textile tissues, is prepared by separating the casein from skimmed milk or buttermilk, and allowing the residual liquid to ferment as long as any increase in its acidity takes place. The resulting solution may be evaporated in a vacuum, at a temperature not exceeding 74° C., to a syrupy consistency or even to the solid state. The syrup, it is stated, contains 18—24 per cent. of free acids, and 14—16 per cent. of acid anhydrides. Citric and lactic acids, lactose, and albuminoids are present in it, but no mineral acids or compounds capable of acting injuriously upon the cellular tissue of skins, or of attacking the gelatin in them.—E. B.

Leather; Process for the manufacture of artificial ——. Mme. J. Guillot, née M. Landivier. Fr. Pat. 362,170, Jan. 5, 1906.

FIBRES of any kind are impregnated with a solution of castor oil and nitrocellulose in acetone, &c., either before, during, or after having been formed into bands or sheets. The latter are then strongly compressed. The proportions used are: fibres, 80 parts; nitrocellulose, 15 parts, and castor oil, 5 parts. Gums and resins may be added to the acetone solution, and other fatty matters substituted for the castor oil.—W. P. S.

XV.—MANURES, Etc.

(*Continued from page* 599.)

Barley; Influence of manures on yield and quality of ——. J. A. Voelcker. J. Inst. Brewing, 1906, **12**, 408—435.

THE author gives an account of the principal results obtained in barley culture, chiefly at the Rothamsted and Woburn stations, and also, but in a minor degree, at other agricultural experimental stations in England and Ireland. In order to arrive at definite conclusions from the experimental treatments the barley is grown on the same land year after year, a course which is never followed in practical agriculture. The experiments showed that unmanured land continuously cropped with barley ultimately becomes exhausted. The same is true with land which receives top-dressings of nitrogenous salts only. The beneficial effects of nitrogenous salts only last for the year of their application; ammonia salts seem to be better adapted for wet seasons, and nitrates for dry seasons. Farmyard manure gives effects which last for a great number of years, and shows especially good results in dry seasons. The continuous application of ammonium salts, alone or with mineral salts, gradually causes failure through the development of an acid condition of the land, a defect which can be remedied by dressing with lime. Nitrogenous salts alone are inimical to good brewing qualities, but ammonia appears to be preferable to nitrates; phosphates are particularly favourable to quality, whilst potash improves the straw. Farmyard and organic manures show uneven results. The best all-round treatment for both yield and quality of barley, when artificial manures have to be used, would appear to be superphosphate, 3 cwt., kainite, 3 cwt., and ammonium sulphate, ¾ cwt., *i.e.*, a complete manure. As regards rotations, barley should not follow roots which have been fed to sheep on the same land; the crops are often too heavy, and the quality is bad. Barley should not be sown after grass, ploughed up, since the land is full of pests and weeds. Good results are obtained after roots which have received farmyard manure, provided the roots are taken off the ground. Perhaps the best results are got when barley follows a white straw crop, preferably wheat which has been manured.—J. F. B.

Calcium cyanamide; Decomposition of ——, [*when used as a manure*]. F. Löhnis. Biedermann's Centr., 1906, **35**, 375—377.

CALCIUM cyanamide is decomposed in ordinary soils by certain bacteria, ammonia, and possibly nitrates, being formed, and its action as a manure is similar to that of ammonium sulphate and sodium nitrate. In boggy soils it is not decomposed, owing to the absence of the necessary bacteria, or is converted by the acids present into compounds which are injurious to vegetation. Experiments show that several species of bacteria are capable of effecting its decomposition, the most powerful being *Bacterium Kirchneri* and *B. lipsiense*. The former is most active at temperatures between 20° and 22° C., and the latter between 10° and 12° C. Whilst mixed cultures of these bacteria effect the complete decomposition of calcium cyanamide, pure cultures of either do not seem to be so effective. The course of the decomposition is not affected by the admission or exclusion of air to the soil, and, consequently, is not helped by derangement of the surface of the soil. Of the above-mentioned bacteria, only *B. Kirchneri* has the power to decompose urea.—W. P. S.

Yeast; The disposal of waste ——. P. Schidrowitz and F. Kaye. XVII., page 650.

ENGLISH PATENT.

Fertilisers [*Phosphate rock and sulphur*] ——. W. B. Chisholm, Charlestown, S. Carolina, U.S.A. Eng. Pat. 6429, March 16, 1906.

PHOSPHATE rock and lump sulphur are reduced to the average size of a pea or bean by passing them together through a preliminary crusher, from 40 to 100 lb. of sulphur being added per ton of mixture. The latter is then ground to a fine powder, and mixed with other ingredients to form a fertiliser. It is claimed that the sulphur under the influence of the moisture of the soil reacts with the phosphate rock, and increases the amount of available phosphate. It also appears to act as a germicide. —W. P. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Reducing sugars; Unification of methods for the determination of ——. L. S. Munson and P. H. Walker. XXIII., page 656.

Starch; The complete conversion into maltose of the dextrins resulting from the saccharification of ——. A. Fernbach and J. Wolff. XVII., page 648.

Sugar industry of Hawaii. For. Off. Ann. Series No. 3643. [T.R.]

THE export of sugar from the Hawaiian Islands during the year ended June 30, 1905, amounted to 371,751 tons, valued at 7,211,738*l.* Of this 362,324 tons, valued at 6,972,229*l.*, was raw sugar, and 9427 tons, valued at 239,509*l.*, was refined sugar; practically the whole export went to the United States.

The total tonnage of the sugar crop for 1904-05 was 426,248 short tons, which is the largest crop in the history of the Islands, with the exception of that for 1903, which exceeded it by 11,743 short tons. There are 53 sugar plantations in the Hawaiian Islands, all of which have their own factories except eight, the latter having their cane ground and manufactured at adjoining factories. Hawaiian sugar is all exported in the raw state with the exception of the output of one factory. In this factory granulated and powdered white sugars only are manufactured, and shipped to San Francisco, its output being about 20,000 short tons per annum.

It is estimated that the area from which the 1905 crop was taken was about 110,000 acres, and that the area now under cultivation, from which the 1906 and 1907 crops are to be harvested, is about double that in extent.

ENGLISH PATENT.

Massecuite, syrups, or impure sugar solutions. Process for purifying ——. J. Wetter, London. From M. Weinrich, Yonkers, N.Y., U.S.A. Eng. Pat. 11,838, June 6, 1905.

SEE Addition of June 9, 1905, to Fr. Pat. 325,882 of 1902; this J., 1905, 1182.—T. F. B.

XVII.—BREWING, WINES, SPIRITS, &c.

(*Continued from page* 604.)

Starch; The complete conversion into maltose of the dextrins resulting from the saccharification of ——. A. Fernbach and J. Wolff. Comptes rend., 1906, **142**, 1216—1218.

CONFIRMING the observation of Maquenne and Roux (this J., 1906, 601) that exceptionally high yields of maltose can be obtained in the conversion of starch paste by malt extract if the medium be nearly neutralised by acid, the authors point out that the addition of acid is by no means a necessary condition for obtaining these high yields. The production of maltose tends to proceed to just as high a limit if no addition be made, provided sufficient time be allowed. Nevertheless a partial neutralisation of the natural alkalinity has a stimulating influence on the activity of the diastase; this influence can be brought into play even when the saccharification of the starch has proceeded to a fairly advanced stage; it is therefore unnecessary to assume that the breakdown of the starch follows a different path in the case of the stimulated diastase. In a series of experiments on the conversion of the same starch by malt extract at 50° C. (*a*) partially neutralised and (*b*) without any addition of acid, the yields of maltose calculated on the original starch amounted, after 94 hours, in the case of (*a*) to 103·8 per cent., and in that of (*b*) to 100·7 per cent. The conversion of starch by diastase into maltose tends to attain the theoretical limit with sufficient time. The slackening observed in the later stages is not due to the failure of the diastase, but to the increasing dilution of the hydrolysable matter. If the residual dextrin be separated from the highly saccharified liquid by precipitation with alcohol, its aqueous solutions are still susceptible to saccharification by malt extract. If any dextrin which is not convertible into maltose exists, it must represent only an infinitesimal fraction of the original starch.—J. F. B.

Diastatic content; Difference in ——, *between malts from large-corned barleys and those from small-corned barleys.* G. Ellrodt. Z. Spiritusind., 1906, **29**, 209—210.

Two barleys having the following characters:—

	Large corn barley.	Small corn barley.
Water, per cent.	14·32	13·64
Nitrogen in dry substance, per cent.	2·058	1·962
Weight per hectolitre (kilos.)	67·6	61·7
,, ,, 1000 corns (grms.)	44·9	29·5
Germinative capacity	96	87

were investigated to ascertain which would give the most suitable malt for distillery purposes. It was found that, with the large-corned sample, the diastatic unit cost double as much as with the other. Barleys with low 1000-corn and hectolitre weights, and high albumin-contents are hence to be regarded as distillery barleys, whilst those with high 1000-corn and hectolitre weights, and low albumin-contents are most suitable for brewing malts.—T. H. P.

Acetic bacterium; Morphological-biological investigation of a new ——. F. Fuhrmann. Z. ges. Brauw., 1906, **29**, 376.

THE author describes a bacterium, named by him *Acetobacter plicatum*, which was isolated from wine in cask, and which converts ethyl alcohol into acetic acid. The infection of the wine with this organism takes place in the press, the grapes on the vine being quite free from it. *Acetobacter plicatum* forms rods 1·4—1·6 μ in length, and 0·4—0·6 μ in breadth. When the bacterium is grown on gelatin, no peptonisation of the medium occurs, even after a week's growth of the organism. On wine- or meat-extract-gelatin the bacterium forms an adhesive, whitish-yellow growth with folds running across the inoculation streak. A similar but more slimy growth is obtained on beer-gelatin, and, in this case, a reddish colour appears after some time. In presence of alcohol, no acid is formed in neutral gelatin media. The optimum temperature is 28°—30° C., but in wine or beer containing a large proportion of alcohol the bacterium grows best at about 25° C. The membrane formed gives with iodine neither a blue coloration nor the cellulose reaction. At temperatures lying between about 22° and 25° C., the organism can be grown in wine containing 11 per cent., or in beer containing 9·5 per cent. of alcohol by weight.—T. H. P.

Proteolytic enzymes; Detection of ——. C. Fermi. Centralbl. Bakt. Abth. II., **16**, 176—191; Z. Spiritusind., 1906, **29**, 221—222.

PROTEOLYTIC enzymes cannot always be detected by their action on fibrin, but the liquefaction of gelatin under antiseptic conditions affords a very reliable and sensitive test for their presence. The process can be applied in various ways, but the following method with solid gelatin is perhaps the best. The concentration of the gelatin solution may vary from 1 to 10 per cent. according to the temperature to be employed. To this solution 0·5 per cent. of phenol is added, and sufficient alkali or acid to create the condition of the medium which may be desired. One c.c. of gelatin solution is placed in each test-tube, these being preserved in a moist condition by storing them with their mouths downwards in a vessel of water. The liquid to be tested (0·5—1 c.c.) mixed with a little phenol or thymol is placed in the tube with the gelatin, and the extent of liquefaction is noted from time to time. The readiness with which the gelatin is liquefied varies inversely as its concentration. The differences in liquefactive capacity are greater with neutral gelatin than with alkaline gelatin; they are also greater at 14° C. than at 20° C. The sensitiveness of the test can be increased by increasing the surface of contact by the addition of some inert insoluble substance such as powdered charcoal. The rate of liquefaction is increased by providing for the draining away of the liquefied products. The detection of proteolytic enzymes in solid animal or vegetable tissues can be effected by placing fragments of the substance, previously sterilised by phenol solution, on the surface of gelatin plates kept in a moist chamber. Proteolytic enzymes can be absorbed from dilute solutions by pieces of fibrin, which can then be tested on the gelatin plates. Another method of detecting the enzymes consists in adding increasing quantities of the solution to a series of gelatin tubes, keeping these at a temperature of 30° C. for several days, cooling to a definite point, and noting the gelatinising power. In some cases, however, the high temperature is injurious to the enzyme. Or else, the quantity of the enzyme solution may be kept constant, and increasing quantities of gelatin may be added. The solid products obtained by the action of dilute alkalis on egg or blood albumin may be used instead of gelatin. They possess

the advantage of remaining solid at temperatures above 30° C., but these bodies are not so sensitive to the action of proteolytic enzymes as gelatin. (See also Schidrowitz, this J., 1903, 958; and 1904, 498.)—J. F. B.

Peroxydases as enzymes with specific activities. A. Bach. Ber., 1906, **39**, 2126—2129.

THE enzyme tyrosinase, discovered by Bertrand, has the specific property of converting tyrosine into a black-coloured oxidation product, whilst it possesses no oxidising action on phenols or aromatic amines. On the other hand, the ordinary oxydases are entirely without action on tyrosine. According to the author's view the oxydases are made up of two complementary enzymes—the peroxydases which "activify" peroxides, and the oxygenases which produce peroxides. The peroxydases are very stable enzymes, whilst the oxygenases are very rapidly destroyed by keeping; in the absence of oxygenases, however, the active system can be re-constituted by the addition of hydrogen peroxide to the peroxydases. The author has applied this rule in the case of tyrosinase in the following manner:—An extract containing tyrosinase was prepared from potatoes; on the addition of alcohol to the extract a precipitate was obtained the solution of which, although still slightly active towards tyrosine, possessed only a fraction of the activity of the original extract. This loss of activity, according to the author's views, should be due to the partial destruction of the oxygenase portion of the system. This was proved to be the case, since on the addition of hydrogen peroxide the solution of the alcoholic precipitate acquired all the activity of the original tyrosinase extract. Consequently, the specific action of tyrosinase is due to the specific nature of its peroxydase portion. The author quotes certain experiments by Palladin which tend to show that the enzymes which bring about respiratory oxidations are oxydases of the same order as the above, *i.e.*, mixed systems of peroxydases and complementary oxygenases. It was found that leaves which had ceased to respire in presence of air, owing presumably to the destruction of their store of oxygenase, could be made to resume their respiratory processes in a very intense degree when hydrogen peroxide was added.—J. F. B.

Acetone; A new microbe which produces ——. L. Bréaudat. Comptes rend., 1906, **142**, 1280—1282.

THE author has obtained from the water supplied to Saigon (Cochin China) an aërobic organism which grows at all temperatures between 30° and 37° C. On peptonised gelatin the cultures are violet, and on potatoes almost black, but no pigment is formed in the absence of peptone or air. The most important property of the organism is that it produces acetone in peptone solutions, the yield being increased by the presence of sugar, and if the medium be kept neutral by the addition of calcium carbonate. Besides liquefying gelatin, the organism reduces nitrates, and coagulates milk. From 10 litres of culture the author has obtained 7·8 grms. of acetone. He proposes to call the microbe *Bacillus violarius acetonicus*.—W. P. S.

Colour of wort and beer: Determination of the —— *, with N/10 and N/100 iodine solutions.* J. Brand and J. Jais. Z. ges. Brauw., 1906, **29**, 337—339.

THE N/10 iodine solution adopted at the Berlin Congress of 1903 as the colorimetric standard for malt worts is not suitable for dark beers of the Bavarian type, because iodine solutions, at the high concentrations necessary for matching the colour intensity of dark beers, have a considerably redder shade than the beer, which renders accurate comparison impossible. For this reason it has always been necessary to dilute such beers before their colour can be determined on the iodine scale. It is, however, possible to reproduce directly the colour of any dark beer by employing the mixture of coal-tar dyestuffs prescribed by Brand (this J., 1899, 935), whereby a standard equal in colour intensity to N/10 iodine, and equivalent in shade at all concentrations to the colouring matter of beer, can be prepared. This solution is more stable than N/10 iodine, and is proposed as a substitute for it in colorimetric work. When the N/100 iodine solution, adopted at the Vienna Congress of 1898, was in vogue, the deepest colour on the scale, *viz.*, 100° = 100 c.c. of water + 100 c.c. of N/100 iodine, was not dark enough for undiluted Bavarian beers. The authors were compelled to create an outside scale, representing from 100° to 200° on this standard, by calling the N/100 iodine solution, or its equivalent in dyestuff, 200°, so that a colour of 190°, for example, would be 190 c.c. of N/100 iodine + 10 c.c. of water.

Hanow (this J., 1903, 1205, and 1904, 380) has given tables for calculating the colour values of the obsolete N/100 scale to their equivalents on the N/10 scale now in use. His principal object was to allow for the fact that on the old colour scale the percentage of extract entered into the result, whereas on the present scale the colour is expressed regardless of the extract. The authors point out that Hanow's tables are founded on an incorrect basis, since he has disregarded the fact that a N/10 iodine solution contains less water than its equivalent of N/100 solution. For example, a colour of 3° on the new scale, which would correspond to 100 c.c. of water + 3 c.c. of N/10 iodine, would, according to Hanow, be equivalent to a colour of 30° on the old scale, which, however, would consist of 100 c.c. of water + 30 c.c. of N/100 iodine. The authors give tables of corrected equivalents.—J. F. B.

Yeast; Production of sulphuretted hydrogen by ——. R. Schander. Jahresber. Ver. angew. Bot., 1904, **2**; Woch. f. Brau., 1906, **23**, 285—286.

THE author conducted fermentations with pure cultures of wine yeasts in fruit and grape musts, in de-alcoholised wines with the addition of sugar, and in artificial nutrient media. Strips of filter paper steeped in a mixture of copper sulphate and lead acetate were placed in the necks of the flasks. All the races of yeast tested gave a greater or less browning of the test papers; as a rule the highly attenuating yeasts showed less than the weakly attenuating varieties, but a few exceptions were noted. The reaction was stronger in the case of cider musts than in that of wine musts. The production of sulphuretted hydrogen was stimulated by higher temperatures and strong aëration. The mycoderma yeasts gave a very strong reaction. The presence of free sulphur is not an essential condition for the production of sulphuretted hydrogen. The formation of sulphuretted hydrogen depends to some extent on the nature of the nitrogenous nutrients; *e.g.*, asparagine is favourable to the formation of the gas, leucine is the reverse, the presence of ultramarine in the sugar has to be taken into account, albumin increases the production, peptone has a slight influence, gelatin causes a strong evolution, isinglass yields no reaction. When the sulphates of potassium, sodium, ammonium, magnesium, and lime were added to the liquids, large quantities of sulphuretted hydrogen were evolved. The reduction of sulphates was very active in the case of mycoderma yeasts and *Oidium lactis*; mould fungi had not the power of reducing sulphates. The addition of powdered sulphur always increased the formation of sulphuretted hydrogen, but its influence was mitigated by the simultaneous addition of albumin or peptone, which, by providing excess of nutrition, diverted the activity of the yeast in another direction. The addition of dead yeast had a similar effect to that of free sulphur. When the sulphur-bearing constituents were added to the musts during fermentation, their effect was much more powerful than when they were present at the start. Dilution of the must with water increased the production of sulphuretted hydrogen. In many cases the browning of the test papers was doubtless caused by organic sulphur compounds such as mercaptans. The production of sulphuretted hydrogen by the yeast is not a simple result of the reducing power or decomposition of the yeast, but rather an essential factor in the vital metabolism, part of the sulphur compounds so produced being doubtless utilised in the synthesis of albumin in the new cells.—J. F. B.

Fruit and grape wines; Formation of sulphuretted hydrogen in ——. Osterwalder. Landw. Jahrb. Schweiz., 1902, 498—504; Woch. f. Brau., 1906, **23**, 285.

THE production of sulphuretted hydrogen in wines has

been attributed either to the presence of free sulphur, derived from the fumigation of the casks, or from the powder employed for the protection of the vines against mildew, or else to the putrefaction of the yeast sediment in the casks. The author made some experiments on the fermentation of pear juice in bottles, some of the samples being fermented by their own yeasts, whilst others were pitched with pure cultures of various Swiss fruit-must yeasts, with or without previous sterilisation. When the bottles were opened after three months, some of them gave a distinct smell of sulphuretted hydrogen, although no free sulphur could have been present, and no putrefaction of the yeast was observed. The varieties of yeast used in the samples which smelt were pure cultures of "Egnach" and "Hutzenwyl" yeasts, and a mixed culture of wild yeast with cultivated "Wadenswel" yeast.—J. F. B.

Spirits; Determination of higher alcohols in ——. P. Schidrowitz and F. Kaye. Analyst, 1906, **31**, 181—191 (See also this J., 1905, 753.)

After testing the degree of accuracy of the Allen-Marquardt process on solutions to which known quantities of amyl alcohol had been added, the authors conclude that the results of the oxidation are accurate with a boiling period of eight hours in the case of spirits containing up to 0·15 per cent. of higher alcohol, which is rarely exceeded in commercial samples. When the quantity of higher alcohol is between 0·15 and 0·2 per cent., fair results can be obtained by extending the time of boiling with the chromic mixture to 10 hours, and quantities up to 0·35 per cent. can be dealt with by boiling for 12 hours. But the authors do not recommend boiling for more than eight hours, and when the result so obtained is as high as 0·14 per cent., it is better to repeat the experiment after diluting the spirit. The authors show that the "mineral acid," presumably hydrochloric acid, which is reputed to be formed in the course of the oxidation is really the organic acid, which reacts to a slight extent as an acid towards Methyl Orange. This reaction of the organic acid can be prevented by adding some non-electrolyte, such as alcohol or acetone, to the liquid to be titrated. The result of the preliminary titration for "mineral acid" in the Allen-Marquardt process may be neglected when the figure obtained does not exceed one-tenth of the total.

Lastly, the authors have tested the colorimetric (sulphuric acid) process, but have come to the conclusion that it is useless. The results vary according to the particular higher alcohol selected as the colorimetric standard, and to the purity of that alcohol. Certain impurities also are present in the commercial spirits to a variable extent which intensify the colorations, and which are not removed in the operation of eliminating aldehydes. So far as this last operation is concerned the authors find that Hewitt's reagent, calcium phenylhydrazine-*p*-sulphonate, is the only agent which eliminates the aldehydes effectively.—J. F. B.

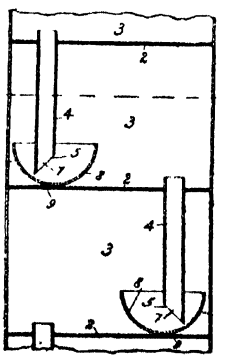
Yeast; The disposal of waste ——. P. Schidrowitz and F. Kaye. J. Inst. Brewing, 1906, **12**, 450—463.

The authors have experimented with two processes of dealing with the waste yeast from breweries (*a*) by destructive distillation; (*b*) by direct conversion into a dry manure.

By the destructive distillation of yeast four main products are obtained, *viz.*, an aqueous liquor containing chiefly ammonia, a fairly thick tar, a large volume of gas, and a species of coke. The yields of the different products vary according to the manner of heating; when the yield of liquor is low, that of the tar is high, and *vice versa*. The results from washed yeast are inferior to those from unwashed yeast. On the large scale a gas retort is better than a still. A sample batch of roughly dried yeast, distilled on the large scale, yielded: liquor, 25 per cent.; tar, 7·6 per cent.; and coke, 48·8 per cent., calculated on the yeast dry-substance. The liquor contained 6 per cent. of ammonia. The tar resembles bone-tar, but is probably superior; the sample obtained above yielded 4·8 per cent. of ammonia when distilled again, and a residue resembling stearin-pitch. The gases are combustible, and can be used for heating the retorts; they contain a large proportion of ammonia, 16 lb. per ton of dry yeast in the above case, which can be removed by washing. The total quantity of ammonia in the above products amounted to 58 lb. per ton of dry yeast. The coke contains important quantities of nitrogen, phosphates, and potash.

The experiments in connection with the direct conversion of waste yeast into manure were carried out with J. L. Baker's process (Eng. Pat. 7921, 1903; this J., 1904, 333), according to which the drying, which is the most difficult problem in dealing with waste yeast, is facilitated by treating the yeast with a small quantity of sulphuric acid, and partially neutralising the acid by the addition of chalk. The mass becomes porous and bulky, after which it is easily dried in open pans, and ground. One hundred tons of pressed yeast yield about 30 tons of product, containing 8 to 9 per cent. of ammonia.

The authors give estimates of manufacturing costs and profits, and of the available supplies of waste yeast in various districts. They point out that, without the co-operation of brewers, no process of dealing with yeast is possible.—J. F. B.



English Patent.

Brewing; Process of ——, *and appliances therefor* [*Boiling and aerating wort*]. C. F. Hyde, Manchester. Eng. Pat. 10,783, May 23, 1905.

A dome-shaped division is placed in the copper boiler at such distance from the bottom as will allow sufficient space below it to accommodate the quantity of wort to be treated. In the centre of the dome is a stuffing-box and gland through which a vertical pipe passes. This pipe may be raised or lowered, and has a number of holes near its lower end. When it is desired to boil the wort under pressure, the pipe is lowered until the holes are under the surface of the wort. As soon as the wort boils, the pressure generated forces a quantity of the liquid up the pipe, at the top of which is a cowl or shield so placed that the liquid is deflected downwards on to the top of the dome. When a certain volume has collected there, a valve is automatically opened, and the liquid returned to the boiler. If it be desired to boil the wort at the ordinary pressure, the pipe is raised until the holes are above the gland, and the wort simply boils over on to the top of the dome, and returns through the valve. A manhole is provided in the dome for cleaning the boiler, &c.—W. P. S.

United States Patents.

Still. J. J. Brennan, Assignor to T. J. Hines, Louisville, Ky. U.S. Pat. 822,573, June 5, 1906.

The fractionating column of the still consists of a tube divided into separate chambers, 3, by perforated plates, 2. The chambers, 3, communicate with one another by the overflow-pipes, 4, having their lower ends, 5, cut away obliquely as shown at, 7, to facilitate the discharge of any

solid matter that may accumulate in the pipes. The overflow-pipes, 4, are sealed at their lower ends by the hemispherical cups, 9, each of which has an inclined side, 8, opposite the oblique opening, 7, so that the rush of liquid from the pipe, 4, may easily wash any solids over the side of the cup.—W. H. C.

FRENCH PATENT.

Ethereal oils contained in flowers and especially in hops; Process of obtaining the ——. L. Nathan. Fr. Pat. 362,252, Jan. 8, 1906. Under Int. Conv., Jan. 19, 1905.

SEE Eng. Pat. 519 of 1906; this J., 1906, 603.—T. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(*Continued from page* 605.)

(*A.*)—FOODS.

Flour; Method for examining bleached ——. R. H. Shaw. J. Amer. Chem. Soc., 1906, **28**, 687—688.

THE natural or "ageing" process for bleaching flour is rapidly being superseded in American mills by artificial methods, amongst which may be mentioned the electric flaming-discharge process, the electro-chemical process, the purely chemical process, and the "exothermic" process. In all the processes on the market the higher oxides of nitrogen play a part, and the proposed method of examination depends on the detection of derivatives of these bodies. About 1 kilo. of flour is boiled for four hours with 95 per cent. alcohol under a reflux condenser. The mixture is cooled and filtered, and the flour is washed once with alcohol. The extract and washings are evaporated nearly to dryness, and the residue is extracted with a mixture of equal parts of alcohol and ether. This extract is filtered, and evaporated to a syrup in a 4-inch porcelain dish. The syrupy mass is then caused to spread itself in a film over the inside of the dish, and a drop of a solution of diphenylamine in sulphuric acid is allowed to trail over the film. In each authentic case of artificial bleaching the drop of reagent used in the above manner left a blue path, whereas no coloration was perceptible in cases of unbleached flour.—J. F. B.

Milk; Absorption of odorous matters by ——. F. Bordas and Toutplain. Comptes rend., 1906, **142**, 1204—1205.

IT is a well-known fact that milk absorbs traces of odorous matters present in the air with extreme facility. In studying this phenomenon the authors selected formaldehyde as the volatile body. They found that when milk was exposed for only one minute to an atmosphere containing formaldehyde, appreciable quantities of that body were absorbed. Further, the presence of formaldehyde could be detected in the milk after a few minutes' exposure, when the atmosphere contained only 1 part of formaldehyde per 100,000. The rapidity of absorption appears to be greater the fresher the milk; it is so great that milk might be used as an absorbent for the detection of traces of formaldehyde in the air. If milk be placed in glass vessels which have contained solutions of formaldehyde, but which have subsequently been thoroughly rinsed, the aldehyde can afterwards be detected in the milk.—J. F. B.

Flours; Detection of rice in wheat ——. G. Gastine. XXIII., page 655.

Flavouring-extracts; Standards for ——. Chem. and Drug., June 23, 1906. [T.R.]

A COMMITTEE of the Association of Official Agricultural Chemists of the United States and the Inter-state Food Commission which was entrusted with the duty of reporting on standards for various foods, has issued a report in which the following are recommended as the strengths of flavouring-extracts. The definition of flavouring-extract is given as "a solution in ethyl alcohol of proper strength of the sapid and odorous principles derived from an aromatic plant, or parts of the plant, with or without its colouring-matter, and conforming in name to the plant used in its preparation." The strengths given are percentages by volume.

Almond Extract.—1 per cent. of oil of bitter almonds derived from the seeds of the bitter almond, apricot, or peach.

Anise Extract.—3 per cent. of oil of anise from aniseed.

Celery-seed Extract.—0·3 per cent. of oil of celery-seed.

Cassia Extract.—2 per cent. of oil of cassia, free from lead, and containing not less than 75 per cent. of cinnamic aldehyde.

Cinnamon extract.—2 per cent. of oil of cinnamon, obtained from the bark of Ceylon cinnamon, and containing not less than 65 per cent. of cinnamic aldehyde and 10 per cent. of eugenol.

Clove Extract.—2 per cent. of oil of cloves.

Ginger Extract.—Containing in 100 c.c. the alcohol-soluble matter from 20 grms. of ginger.

Lemon Extract.—Prepared from oil of lemon, lemon-peel, or both; contains 5 per cent. of oil of lemon.

Terpeneless Extract of Lemon.—Prepared by shaking oil of lemon with dilute alcohol; contains 0·2 per cent. by weight of citral derived from the oil of lemon.

Nutmeg Extract.—2 per cent. of oil of nutmeg.

Orange Extract.—Prepared from oil of orange, orange-peel, or both; contains 5 per cent. of oil of orange.

Peppermint Extract.—3 per cent. of oil of peppermint.

Rose Extract.—Prepared from otto of roses with or without red-rose petals; contains 0·4 per cent. of otto of roses.

Savory Extract.—0·35 per cent. of oil of savory.

Spearmint Extract.—3 per cent. of oil of spearmint.

Star-anise Extract.—3 per cent. of oil of star-anise.

Sweet Basil Extract.—0·1 per cent. of oil of sweet basil.

Sweet Marjoram Extract.—1 per cent. of oil of marjoram.

Thyme Extract.—0·2 per cent. of oil of thyme.

Tonka Extract.—From tonka-bean, with or without sugar or glycerin; contains 0·1 per cent. by weight of coumarin with a corresponding proportion of the other soluble matters.

Vanilla Extract.—From vanilla-bean, with or without sugar or glycerin; contains in 100 c.c. the soluble matters from 10 grms. of vanilla-bean.

Wintergreen Extract.—Contains 3 per cent. of oil of wintergreen.

ENGLISH PATENT.

Baking powder; Manufacture of a ——. L. Weil, Strasburg, Germany. Eng. Pat. 15,667, July 31, 1905.

TARTARIC acid is mixed with about one-tenth of its weight of paraffin or other solid hydrocarbon, and warmed in order that the paraffin shall form a coating over the tartaric acid crystals. The mixture is then stirred until cold, and mixed with suitable quantities of sodium hydrogen carbonate and starch to produce the baking powder claimed. The purpose of the paraffin is to retard the action of the acid.—W. P. S.

FRENCH PATENTS.

Cocoa substitutes; Process of manufacturing ——. J. Meinl. First Addition, dated Dec. 9, 1905, to Fr. Pat. 316,861, Dec. 13, 1901 (this J., 1902, 1344).

SUGAR and other ingredients are added to the cocoa and malt preparation described in the original specification, in order to form a chocolate. The product is not deprived of its excess of fat.—W. P. S.

Milk; Process and apparatus for the concentration and preservation of ——. C. Joanne and E. Borde. Fr. Pat. 362,248, Jan. 8, 1906.

THE milk is heated to a temperature not exceeding 70° C., and is concentrated by the passage of a current of hot dry air over its surface, the temperature of the air being not more than 50° C. The concentrated milk is placed in bottles, and sealed under vacuum at a temperature of 40° C. The bottled milk is sterilised by heating it repeat-

edly on alternate days to 76° C., being kept at 36° C. on the other days. The apparatus for concentration consists of a closed cylinder in which the milk is placed and heated; a series of discs mounted on a rotary shaft is placed in the cylinder, so that when the shaft is revolved, the milk is carried round on the discs in a thin layer which is exposed to the current of hot dry air which enters at one end of the cylinder, whilst the saturated air escapes at the other end.—J. F. B.

Fruit; Process of preparing concentrated juices and extracts of ——. O. Volz. Fr. Pat. 362,247, Jan. 8, 1906. Under Int. Conv., Jan. 10, 1905.

See Eng. Pat. 612 of 1905; this J., 1906, 332. T. F. B.

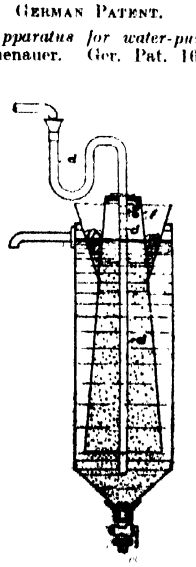
(*B.*)—SANITATION; WATER PURIFICATION.

English Patents.

Towns' refuse; Apparatus for forcing and promoting the combustion of ——, *in destructor furnaces.* F. Aslatt, Southampton. Eng. Pat. 16,204, Aug. 9, 1905.

The invention deals with the application of compressed air highly charged with water to a closed space or ash-pit below the furnace grates. For this purpose the injector described in Eng. Pat. 16,203 of 1905 is mounted on the front wall or plate of the ash-pit. It consists of a perforated conical nozzle, through which air is forced by an air-compressing engine; within this nozzle there is a water pipe having a perforated nozzle coincident with the exit end of the air nozzle. The water is drawn up this pipe, and broken up into a very fine spray by the air-blast. Over the combined air and water nozzles is fitted a screw-cap device to regulate the air and water blast, and around the whole is placed an air induction funnel. The water supply may also be regulated by a tap fitted on the water pipe. The air and water blast passes from the ash-pit upwards through the grate and burning refuse, and accelerates the combustion of the latter.—W. P. S.

Distilling water by the multiple-effect system, and apparatus therefor. W. Clark, London. From American Water Purifying Co., Philadelphia, U.S.A. Eng. Pat. 16,177, Aug. 8, 1905.



See Fr. Pat. 356,762 of 1905; this J., 1905, 1319.- T. F. B.

French Patent.

Carbon dioxide in the atmosphere of rooms, &c.; Apparatus for the determination of ——, *and for other purposes.* A. A. Lévy and A. Pecoul. Fr. Pat. 362,199, Jan. 6, 1906. XXIII., page 655.

German Patent.

Lime-saturation apparatus for water-purifying installations. F. Eichenauer. Ger. Pat. 164,713, May 25, 1904.

The air evolved from the incoming water collects in the upper part, *f*, of the saturator, and is then sucked in through perforations, *g*, by the water flowing down the inlet pipe, *d*, and is utilised for agitating the mixture of lime and water in the lower part of the saturator.—A. S.

XIX.—PAPER, PASTEBOARD, Etc.

(*Continued from page* 606.)

Cellulose; Note on the constitution of ——. A. G. Green and A. G. Perkin. Chem. Soc. Trans., 1906, **89**, 811—813.

The chief objection to the constitutional formula for cellulose proposed by Green (this J., 1904, 382).

$$\begin{matrix} CH(OH).CH & -CH(OH) \\ \cdot & >O \quad >O \\ CH(OH).CH & -CH_2 \end{matrix}$$

lies in the fact it contains only three hydroxyl groups, and should therefore only yield a triacetyl derivative on complete acetylation, whereas it has been generally accepted hitherto that the highest product of the acetylation of cellulose (without concomitant hydration) is a tetra-acetyl derivative. The authors have now determined by three different methods the number of acetyl groups in this supposed tetra-acetyl compound, prepared in the usual manner from cellulose regenerated from the xanthate (see Cross, Bevan, and Beadle, Chem. Soc. Trans., 1895, **67**, 447). The results show clearly that the product contains only three acetyl groups. It is pointed out that the formula given above is only intended to represent cellulose in its simplest or unpolymerised form, as, for instance, in an ammoniacal cupric solution. The cellulose of fibres may consist of a number of these C_6 complexes united together by means of their oxygen atoms, or, as is more probable, of a physical aggregate of molecules of cellulose of the constitution given.—A. S.

Copper-alkali-cellulose. W. Normann. Chem.-Zeit., 1906, **30**, 584-585.

Linkmeyer's process for the manufacture of artificial silk depends on the coagulation of a cuprammonium solution of cellulose by a solution of caustic soda. The coagulated thread, instead of becoming milky white as is the case when an acid coagulating bath is used, remains blue and perfectly transparent. This is due to the formation of a copper alkalicellulose, by the displacement of ammonia by soda in the cellulose compound. Cupric hydroxide dissolves to a slight extent in concentrated soda lye giving a blue solution. If cotton be immersed in this solution the ordinary phenomena of mercerisation are observed, but at the same time the fibre is coloured deep blue, and the liquid is decolorised. By repeatedly renewing the copper solution a saturation point is reached at which the cellulose ceases to absorb more copper. The compound can then be washed without dissociation by means of soda lye of a certain strength, and analysis shows a ratio of cellulose to copper in the saturated compound corresponding to the formula $C_{12}H_{20}O_{10}.CuO$, or 23·15 per cent. of copper oxide. The copper-alkali-cellulose compound is dissociated by water, pale blue copper hydroxide being precipitated in the thread. The precipitation of a cuprammonium solution of cellulose by substitution of the alkali requires a certain concentration of the soda lye; conversely the soda in the coagulum can be displaced if a large excess of concentrated ammonia be employed, and the soluble ammonium compound is regenerated. Consequently copper-alkalicellulose can be produced in solutions rich in copper by adding sufficient caustic soda lye to a solution of cuprammonium. The threads of artificial silk coagulated in a caustic soda bath, and washed in soda lye are deep blue in colour; the copper is immediately removed by dilute acids, and the decolorised threads retain their perfect transparency.

English Patents.

Paper; Manufacture of ——, *by the web machine.* C. E. Armengaud, sen., Paris. Eng. Pat. 1377, Jan. 18, 1906. Under Int. Conv., Jan. 21, 1905.

See Fr. Pat. 359,419 of 1905; this J., 1906, 389.—T. F. B.

Waste-water of a paper machine; Procedure for the direct utilisation of the ——. M. Erfurt, Straupitz, Germany, Eng. Pat. 5851, March 10, 1906. Under Int. Conv., March 20, 1905.

See Fr. Pat. 352,524 of 1905; this J., 1905, 984.—T. F. B.

United States Patent.

Cellulose [Cotton seed hulls]. J. S. Cochran, Philadelphia, Pa., Assignor to F. Taylor, Wilmington, Del. U.S. Pat. 822,430, June 5, 1906.

A mechanical process is specified for recovering the fuzz of the hull of the cotton seed in a pure and unchanged condition after all the staple fibre and lint have been removed from the hull, and bleached.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

(*Continued from page* 608.)

Autocatalysis and decomposition of a photochemical system [Iodoform]. B. Szilard. Comptes rend., 1906, **142**, 1212—1214.

A solution of iodoform in chloroform, when exposed to the action of light in presence of oxygen, gradually decomposes, with liberation of iodine. When this decomposition has once started, it continues spontaneously even in the dark. The spontaneous decomposition of the solution is not complete even after 100 days, but if mercury be added, and if the liquid be shaken occasionally to absorb the iodine produced, the decomposition proceeds to the end. If a solution which has been decomposed by light, be mixed with a solution which has been prepared in the dark, it brings about the decomposition of the latter. The decomposition partakes of the nature of a purely catalytic reaction, the catalytic agent being produced by the reaction itself. Nevertheless, the catalytic substance is not definitely liberated, since the rate of decomposition does not show an increase up to a certain limit. The phenomenon is not limited to solutions of iodoform in chloroform, but proceeds also in other solvents. A small quantity of oxygen is quite as effective as a large quantity. The authors have worked out an expression representing the course of the reaction. In order to study the influence of light apart from that of the autocatalysis pure and simple which goes on in the dark after a short exposure to light, this exposure must in the latter case be as short as possible, and in the former case as complete as possible; the difference between the two curves represents the influence of the light factor.—J.F.B.

Mercuric iodide and methylamine; Compounds of ——. M. François. Comptes rend., 1906, **142**, 1199—1202.

On passing gaseous methylamine over mercuric iodide, a turbid liquid is finally obtained, from which, after standing, the clear liquid may be decanted. This latter, when again saturated with methylamine, yields the compound, $HgI_2,5CH_3NH_2$, in the form of a colourless liquid, which solidifies at —46° C. The compound can be preserved indefinitely in sealed tubes, but when exposed to the air, it loses methylamine, and yields crystals of the compound. $HgI_2,2CH_3NH_2$. This compound forms colourless prisms having an ammoniacal odour; it loses methylamine very slowly when exposed to the air, but can be kept unaltered in closed bottles. It can also be prepared by introducing a solution of potassium iodide saturated with mercuric iodide into excess of a solution of methylamine. A third compound of mercuric iodide and methylamine, HgI_2,CH_3NH_2, can be obtained by leaving for five days a small crucible containing the compound, $HgI_2,2CH_3NH_2$, in a large closed flask containing some mercuric iodide, or by introducing methylamine into excess of a solution of potassium iodide saturated with mercuric iodide.

—A. S.

Mercury oxychlorides; Production of ——. M. Dukelski. Z. anorg. Chem., 1906, **49**, 336—337.

On mixing boiling concentrated aqueous solutions of borax and mercuric chloride, a precipitate of small deep-brown needle-shaped crystals is obtained, while the mixing of more dilute solutions at 40° C. causes a precipitate of shining golden-yellow plates. These two precipitates are identical in composition, and have the formula $4HgO.HgCl_2$.—J. T. D.

Bismuth; Contribution to the study of ——. J. Aloy and P. Frébault. Bull. Soc. Chim., 1906, **35**, 396—406.

Bismuth potassium chloride, $BiCl_3.2KCl$.—Dry chlorine is passed over bismuth heated to 250° C., and the resulting vapour of bismuth chloride allowed to pass over potassium chloride heated to dull redness in small boats. The alkali chloride is first coloured brown, then the mass melts, and when the action is complete in the first boat it spreads to the second, and so on. Bismuth-potassium chloride is a light amber-coloured crystalline compound, somewhat deliquescent, but not so much so as bismuth chloride. Excess of water converts it into bismuth oxychloride.

Bismuth potassium bromide, $BiBr_3.2KBr$, is prepared in a similar manner to the chloride, but after the reaction is ended, it is cooled in an atmosphere of carbon dioxide. It is a well-defined crystalline substance, more highly coloured than the chloride. On heating, it gradually changes from yellow to brownish-red, and melts at about 600° C. without volatilising.

Bismuth hydrogen bromide, $BiBr_3.2HBr.4H_2O$, is obtained as bright yellow needles by dissolving bismuth bromide in concentrated aqueous hydrobromic acid till saturated, and cooling the solution to —10° C. It is deliquescent, and readily decomposes in the air with evolution of hydrobromic acid.

In attempting to make alkali bismuthates by allowing a solution of bismuth nitrate in nitric acid to fall drop by drop into boiling caustic alkali, large needles of indefinite composition were obtained, varying in colour according to the strength of the alkali. These crystals contained bismuth and oxygen in the proportion Bi_4O_7; they were anhydrous, insoluble in water, soluble in alkalis, and decomposed on treating with hydrochloric acid with evolution of chlorine.—B. J. S.

Alcoholates and alkyl-carbonic acid esters; Electrolytic preparation of ——. B. Szilard. XIA., page 642.

English Patents.

Dialkylbarbituric acids; Manufacture of ——. G. B. Ellis, London. From E. Merck, Darmstadt, Germany. Eng. Pat. 11,219, May 29, 1905.

Pharmaceutical compounds [Alkyloxyacetylcatechol ethers]; Manufacture of new ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 25,571, Dec. 8, 1905.

See U.S. Pat. 822,339 of 1906; following these.—T. F. B.

Fats; Manufacture of iodine [iodised] ——. H. A. Pryor, London. From Chem. Fabr. von. Heyden, Akt.-Ges. Radebeul, Germany. Eng. Pat. 3132, Feb. 8, 1906.

A fat with a low iodine value, *e.g.*, cocoanut oil or cacao butter, is treated with an iodising agent other than hydriodic acid or a chloriodide. Thus, cocoanut oil is mixed, at about 50° C., with alcohol and a solution of iodine in alcohol, and the mixture stirred with a solution of iodic acid in alcohol for about an hour, after which the oil is separated, washed with alcohol, and dried at a low temperature. The product, which contains about 5 per cent. of iodine, is crystalline when cold, has an agreeable taste, and is very stable if protected from light.—C. A. M.

United States Patents.

Pyrocatechinmonoethyl ether; Alkyloxyacetyl compound of ——. R. Berendes, Assignor to Farbenfabr. vorm F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 822,339, June 5, 1906.

Alkyloxyacetylcatechol alkyl ethers are obtained by the action of alkyloxyacetyl chlorides on catechol mono-

alkyl ethers. They possess valuable therapeutic properties, and are decomposed by dilute caustic alkalis. The compound obtained by the action of ethoxyacetyl chloride on guaiacol is a colourless oil, b.pt. 150° C. (10 mm. pressure), soluble in alcohol and ether, and decomposed by alkali hydroxides into guaiacol and ethoxyacetic acid. T. F. B.

Pharmaceutical compound. F. Hofmann, Elberfeld, Germany, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 822,370, June 5, 1906.

See Fr. Pat. 355,367 of 1905; this J., 1905, 1189.—T. F. B.

Dialkylmalonyl ureas; Process of making ——. G. Keil, Assignor to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on the Maine, Germany. U.S. Pat. 822,672, June 5, 1906.

See Eng. Pat. 26,275 of 1905; this J., 1906, 233.—T. F. B.

Beryllium hydroxide; Process of making ——. F. Haber and G. van Oordt, Karlsruhe, and F. Bran, Mannheim, Germany. U.S. Pat. 822,444, June 5, 1906.

See Fr. Pat. 340,027 of 1904; this J., 1904, 799.—T. F. B.

French Patent.

Esters of fatty acids; Process for the decomposition of ——. Ver. Chem. Werke Akt.-Ges. First Addition, dated Dec. 11, 1905, to Fr. Pat. 328,101, Oct. 9, 1902. Under Int. Conv., Jan. 25, 1905.

The esters are subjected to the action of vegetable ferments in the presence of water and manganese sulphate or other metallic salt. Acetic acid may be added at the beginning of the operation, or that formed during the fermentation may be utilised; in the latter case the decomposition is somewhat slower.—W. P. S.

German Patents.

Alkylapomorphinium salts; Process for preparing easily soluble, stable ——. J. D. Riedel, A.-G. Ger. Pat. 167,879, July 30, 1903. Addition to Ger. Pat. 158,020, July 30, 1903 (see this J., 1905, 750).

Stable, soluble alkylapomorphinium salts are obtained by the action of metallic salts (*e.g.*, potassium bromide) on concentrated solutions of the salts of alkylapomorphinium bases with an alkyl hydrogen sulphate.—T. F. B.

C.C-Dialkyl-2.4-diimino-6-oxypyrimidines; Process for preparing ——. E. Merck. Ger. Pat. 168,405, Dec. 20, 1903. Addition to Ger. Pat. 162,657, Nov. 10, 1903 (this J., 1905, 1255).

Dialkylcyanoacetic esters and guanidine can be condensed without the aid of a condensing agent, to form dialkyl-2.4-diimino-6-oxypyrimidines. The products are stated to be particularly pure.—T. F. B.

Dialkylbarbituric acids; Process of preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 168,406, July 7, 1904. Addition to Ger. Pat. 163,136, March 30, 1904.

Alkali metals or their amides may be used in place of alkali alcoholates in the condensation of dialkylmalonic acid diamides and normal carbonic acid esters to form dialkylbarbituric acids.—T. F. B.

p-Dialkylaminobenzhydralamines; Process for preparing ——. E. Merck. Ger. Pat. 167,462, Jan. 9, 1904.

p-Dialkylaminobenzhydralamines are obtained by the action of ammonia on dialkylaminodiphenylcarbinols or their ethers or halogen acid esters. (See also Ger. Pat. 167,462 of 1904; this J., 1906, 608).—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

(*Continued from page* 609.)

Fixation; Theory of ——, *and the action of thiosulphate on development.* S. E. Sheppard and C. E. K. Mees. Phot. J., 1906, **46**, 235—254.

The velocity of fixation of photographic emulsions (*i.e.*, solution of silver halide in the thiosulphate) is directly proportional to the concentration of the thiosulphate solution. It increases rapidly at first, and afterwards becomes constant. The presence of an alkali bromide has no effect on the velocity; neither has "tanning" of the gelatin (by means of formaldehyde), or prolonged exposure of the emulsion to light. Hydrogen and hydroxyl ions slightly increase the velocity of solution. The course of the fixation may be divided into three main reactions which take time (1) "macro-diffusion" through the film, *i.e.*, diffusion combined with absorption; *invasion or penetration*; (2) "micro-diffusion" through the membrane of the grain, very possibly this membrane is only semi-permeable with respect to certain ions; *permeation*, (3) the chemical action itself. With solvents of sufficient concentration, fixation depends mainly on (1) and (2). When thiosulphate is present in acid developers, the rapidity of development is increased; in alkaline developers it is retarded; it is considered probable that, in the former case, silver sulphide is formed and deposited on the image, more especially on the exposed portions, thus causing more rapid development, and, at the same time, fog. In alkaline development, formation of sulphide would be prevented by the presence of hydroxyl ions and SO_3 ions.—T. F. B.

Silver bromide emulsion for the printing-out process. E. Valenta. Brit. J. Phot., 1906, **53**, 466.

Silver bromide emulsified in collodion is found to be suitable for preparing printing-out papers. Bromides of lithium, calcium, and strontium are best suited to the process, the amounts used being so chosen that about one-half of the silver is combined with bromine. The emulsions may contain 18 grms. of silver per litre of 2·5 per cent. collodion. The prints have a purple-violet tone, which changes to yellowish-brown on fixing: they may be toned with gold or platinum, and give reddish or purple-brown tones.—T. F. B.

Asphaltum; Action of light on . V. Vojtech. Phot. Corr., **63**, 284. Phot. J., 1906, **46**, 259.

Glass strips were coated on both sides with a 4 per cent. solution of asphaltum in benzene, and exposed to the action of light in presence of hydrogen, nitrogen, oxygen, carbon dioxide, and air. In presence of air and oxygen, considerable absorption of the gas was noted, and the asphaltum became insoluble in oil of turpentine; the absorption occurred rapidly at first, and the velocity decreased gradually until maximum absorption was attained; the amount of absorption depends on the intensity of the light. In presence of nitrogen, hydrogen, and carbon dioxide, no absorption was observed, and the asphaltum remained soluble as if unexposed. The results were similar whether dry or damp gases were employed, and whatever the variety of asphaltum used. Heat has an action similar to that of light upon asphaltum, which is rendered insoluble by heating to 100° C.—T. F. B.

English Patents.

Photographic film. L. Smith, Croydon. Eng. Pat. 16,999, Aug. 22, 1905.

A celluloid or similar base is coated on each side with one or more layers of gelatin silver emulsion, the layer on the top of the base being faster than that beneath it, or, if more than one layer of emulsion is applied to each side of the base, the speeds of the layers are graduated from top to bottom. The resulting film is stated to be capable of receiving long exposure without exhibiting

the effects of over-exposure, the slower emulsion absorbing the rays of light which have passed through the more rapid layer.—T. F. B.

Photographic printing; Impts. in ——. T. Manly, London. Eng. Pat. 17,007, Aug. 22, 1905.

A PAPER coated with pigmented gelatin is immersed for a short time in a solution containing an alkali bromide, ferrocyanide, and bichromate, and is then laid, face upwards, on a glass plate; a silver bromide or other image consisting of silver is moistened, and placed, face downwards, in contact with the gelatin paper, and the whole allowed to remain for 20 to 30 minutes; the silver is stated to react with the bromide and ferrocyanide, with evolution of hydrogen, which reduces the bichromate, the reduction products of which render the gelatin insoluble. The two papers may now be separated by soaking in hot water, in which case the silver print is converted into a pigment print, or they are soaked in cold water, and separated, and the gelatin layer transferred from its support to a permanent support in the usual way; in this latter case, the bromide print may be redeveloped, and again utilised.—T. F. B.

UNITED STATES PATENT.

Photographic plate for colour photography. A. and L. Lumière, Lyon-Monplaisir, France. U.S. Pat. 822,532, June 5, 1906.

SEE Eng. Pat. 25,718 of 1904; this J., 1905, 152.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

(*Continued from page* 609.)

Gelatin-dynamite; Chemical analysis of ——. T. B. Stillman and P. F. Austin. XXIII., page 656.

ENGLISH PATENT.

Explosives; Manufacture of ——. W. Macnab and Ammonal Explosives, Ltd., London. Eng. Pat. 16,514, Aug. 14, 1905.

THE addition of potassium bichromate to explosives of the "ammonal" type enables a larger proportion of aluminium to be used, so that the explosive force is increased without adding to the danger of igniting fire-damp. A satisfactory composition is as follows:—Ammonium nitrate, 85·5; aluminium, 8; charcoal, 2·5; and potassium bichromate, 4 per cent. An equivalent proportion of a hydrocarbon, such as paraffin or naphthalene, or of a nitrohydrocarbon, such as dinitrobenzene, may be used in place of the charcoal.—C. A. M.

XXIII.—ANALYTICAL CHEMISTRY.

(*Continued from page* 611.)

APPARATUS, ETC.

FRENCH PATENT.

Carbon dioxide in the atmosphere of rooms, &c.; Apparatus for the determination of ——, *and for other purposes.* A. A. Lévy and A. Pecoul. Fr. Pat. 362,199, Jan. 6, 1906.

THE apparatus employed, consists of a reservoir filled with water, and by means of which, suitable tubes being provided, a known volume of the air can be aspirated through the absorbing part of the apparatus. This consists of a U-tube having a bulb on each limb and three small bulbs at its bend or lower part. Before commencing the operation, a measured volume of alkali is placed in the U-tube, and after the air has been aspirated through it, an acid solution is added. If the indicator present is not decolorised, the quantity of carbon dioxide present is less than 10 parts per 10,000. Additional supplies of alkali and acid are provided, by means of which, with the aid of pipettes, the excess of carbon dioxide above this quantity may be determined.—W. P. S.

INORGANIC—QUALITATIVE.

Phosphorus; Qualitative test for ——. Mauricheau-Beaupré. Comptes rend., 1906, 142, 1206—1207.

THE vapours of phosphoric acid possess the property of etching glass when the latter is heated at a temperature near its fusing point. A short, hot flame should be used, *e.g.*, that of acetylene or hydrogen burning in a Bunsen burner. Whichever gas be employed it is necessary to purify it by absorbing any phosphoretted hydrogen in a tower containing sulphuric and chromic acids. A small piece of glass tubing, 5—10 mm. in diameter, is supported on a platinum wire at the top of the flame in the exterior zone of oxidation, the glass is heated to the fusing point, and the vapours of the substance to be tested are mixed with the gas in the burner. After 10 minutes, etching of the glass is observed if phosphorus be present; this etching action takes place with a slight gain in weight, and with the fixation of phosphorus in the glass. The phosphorus in iron can be liberated by acids, and the gas can be conducted into the air-holes of the burner. In the case of organic compounds, the substance is placed on a platinum wire, and is burnt in the upper part of the blue cone of the flame, the piece of glass being at the top of the flame.—J. F. B.

Gold and platinum; Detection of ——. J. Petersen Z. anal. Chem., 1906, 25, 342—344.

To the faintly acid solution containing gold and platinum, an excess of zinc turnings is added. Mercury, silver, lead, bismuth, copper, cadmium, platinum, gold, arsenic, antimony, tin, and some cobalt and nickel are precipitated on the zinc. After warming for 15 minutes, the precipitate is filtered off, washed, and warmed with dilute hydrochloric acid, which dissolves the cadmium, tin, and excess of zinc, together with some cobalt. The solution is filtered, and the undissolved metal well washed, and then boiled with dilute nitric acid. Mercury, lead, copper, bismuth, and nickel are dissolved, and the residue, now consisting only of gold, platinum, and antimony, is dried and mixed with 1–2 parts of ammonium nitrate and 5 parts of ammonium chloride, and is then ignited in a porcelain crucible. Antimony is volatilised as chloride, and the residue may now be dissolved in a few drops of *aqua regia*, and tested for platinum and gold.—F. SODN.

INORGANIC—QUANTITATIVE.

Cadmium; Determination of ——. C. Goldschmidt. Z. anal. Chem., 1906, 25, 344.

CADMIUM is precipitated completely from solutions of its salts on boiling these in aluminium vessels in presence of a trace of chromium nitrate and cobalt nitrate. The aluminium acts as the catalytic agent. The precipitation is as complete as that of gold by nickel, or that of silver by cobalt, on boiling the solutions.—F. SODN.

Silicates [Glass]; Decomposition of —— *[for analysis].* F. Hinden. Z. anal. Chem., 1906, 25, 332—342.

FOR success in the method described, it is essential that the substance should be reduced to an impalpable powder. After drying, 1 grm. is weighed into a platinum dish, moistened with water, and 10—15 c.c. of concentrated hydrofluoric acid added. After evaporating to dryness on the water-bath, and taking up in 5—10 c.c. of hydrochloric acid (1:1), another 10 c.c. of hydrofluoric acid are added, and the solution is again evaporated to dryness. The silicon will now have been volatilised; the solution is next evaporated six times on the water-bath with 10—20 c.c. of hydrochloric acid (1:1) to completely convert all the bases into chlorides. These are then dealt with in the usual way. The method has been found to give good results with many natural silicates, and also with artificial silicates such as glass.—F. SODN.

ORGANIC—QUALITATIVE.

Flours; Detection of rice in wheat ——. G. Gastine. Comptes rend., 1906, 142, 1207—1209.

THE detection of rice flour in wheat flours is greatly

solitated by treating a trace of the sample on an object lass with a solution of a suitable dyestuff, drying the reparation at about 30° C., and then completing the esiccation by heating for a few minutes at 110°—130° C. The preparation should be mounted in cedar-wood oil or anada balsam and examined under the microscope. For taining, a solution of Aniline Blue or Green may be em-loyed at a strength of 0·05 grm. in 100 c.c. of 33 per cent. lcohol. This treatment has the effect of showing up the ilum of the minute rice-starch granule, whilst wheat starch arely exhibits a visible hilum. In rice flour isolated tarch granules are rare, the granules generally occurring n clusters in starch-bearing cells, several of which may be een together in fragments of the grain. These clusters, ccording to the above method, have a very characteristic ppearance, since the hilum of each starch granule shows p as a reddish-coloured point, these red points being rouped quite uniformly in a symmetrical arrangement esembling a mulberry under a high magnification. Wheat and rice starches do not take up the dyestuff, nly the nitrogenous matters are dyed. The fragments f rice flour therefore appear coloured; the medium sized nd large granules of wheat starch are practically un-oloured, but the small granules of the wheat, in which he interstitial nitrogenous matter is more abundant, are listinctly coloured. The granules of maize and buck wheat starches behave like rice. Potato, arrowroot, and weet-potato starches, unlike the cereal and leguminous tarches, absorb the dyestuff directly.—J. F. B.

ORGANIC—QUANTITATIVE.

Reducing sugars; Unification of methods for the determination of ——. L. S. Munson and P. H. Walker. J. Amer. Chem. Soc., 1906, **28**, 663—686.

The authors recommend the following as a standard method for the determination of reducing sugars. The copper sulphate solution contains 34·639 grms. per 500 c.c.; the alkaline tartrate solution contains 173 grms. of Rochelle salt and 50 grms. of sodium hydroxide per 500 c.c. Twenty-five c.c. of each solution are placed in a Jena beaker of 400 c.c. capacity, and 50 c.c. of the sugar solution are added; if a smaller quantity of sugar solution be desirable, the balance must be made up by water. The beaker, covered by a watch-glass, is heated upon an asbestos-gauze with a flame so regulated that boiling begins in four minutes, and ebullition is continued for exactly two minutes. The cuprous oxide is then filtered off immediately, without diluting, on to an asbestos felt in a Gooch crucible. It is washed with hot water, and finished off with 10 c.c of alcohol, followed by 10 c.c. of ether; the crucible is then dried for 30 minutes in a water-oven, and weighed. The preparation of the asbestos consists of a prolonged digestion with hydrochloric acid, followed by a digestion with "soda" solution, an extraction with boiling diluted alkaline tartrate solution, and digestion with nitric acid. The Fehling's solution deposits a little cuprous oxide when boiled alone without sugar; a blank experiment made each day will correct this error and that due to the solubility of the asbestos in the alkaline liquid. "The presence of sucrose materially increases the reduction of the copper, the amount of increase being influenced primarily by the amount of sucrose present, and secondarily by the amount of invert sugar present." "The amount of sucrose remaining the same, its influence will be less when a large amount of reducing sugar is present than when only a small amount is present." The authors have drawn up tables for use with this method, the values of which are summarised in the following formulæ where y = mgrms. of cuprous oxide and x = mgrms. of reducing sugar:—

For dextrose, $y = 0{\cdot}5614 + 2{\cdot}3484x - 0{\cdot}001209x^2$.
For invert sugar alone, $y = -0{\cdot}2460 + 2{\cdot}2747x - 0{\cdot}001077x^2$.
For invert sugar and sucrose, total sugars = 0·4 grm., $y = 6{\cdot}9886 + 2{\cdot}2279x - 0{\cdot}000703x^2$.
For invert sugar and sucrose, total sugars = 2·0 grms., $y = 20{\cdot}6690 + 2{\cdot}0921x - 0{\cdot}000930x^2$.—J. F. B.

Gelatin-dynamites; Chemical analysis of ——. T. B. Stillman and P. T. Austin. Bull. Soc. Chim., 1906, **35**, 373—376.

The dynamite is cut into small pieces, and the moisture determined by allowing 10 grms. to dry over calcium chloride to constant weight. The residue is digested in the cold, with frequent shaking, for two hours in an Erlenmeyer flask with 200 c.c. of a mixture of 1 part of alcohol and 2 parts of ether, and decanted through a weighed filter, extraction being repeated with fresh solvent until a drop of the extract shows no residue on evaporation. A solution (1) and a residue (2) are thereby obtained.

Solution (1) is evaporated to 100 c.c. without heating, and on adding 100 c.c. of chloroform, and agitating, the soluble nitrocellulose is precipitated, and is dried at 60° C., and weighed. The filtrate is slowly evaporated in a current of air to constant weight. The residue, which consists of a mixture of nitroglycerin, resin, sulphur, paraffin, and nitrates, is extracted with small quantities of cold water to dissolve nitrates of potassium, sodium, and ammonium. Resin may be estimated in the portion which remains by titration with N/1 alcoholic potash. Excess of potash is then added, the mixture is evaporated nearly to dryness so as to completely hydrolyse the nitroglycerin, and the residue is dissolved in water, and extracted with ether. The extract contains resin and paraffin. The aqueous solution is treated with bromine to oxidise sulphur, acidified with hydrochloric acid, warmed, and cooled to 15° C. Resin separates, and is filtered off, dried, and weighed. The solution is precipitated with barium chloride, and the sulphur weighed as barium sulphate, whilst the nitroglycerin is obtained by difference.

Residue (2) is dried at 60° C., cooled, and weighed. Nitrates are extracted with hot water, and estimated in the filtrate. The undissolved residue which contains sulphur and wood pulp is dried at 70° C., and weighed. The sulphur is then separated by digesting with carbon bisulphide, and the residual wood pulp dried at 60° C., and weighed.—B. J. S.

Trade Report.

JAPANESE TARIFF; NEW ——.

Bd. of Trade J., June 14 *and* 28, 1906.

The complete customs tariff of Japan was published on June 14th last as a supplement to the issue of the Board of Trade Journal of that date.

The issue of the Board of Trade Journal for June 28th contains the following notes of errata:—

(i.) *Tariff No.* 129.—*Carbonate of magnesia.*—The new rate is 2·730 yen per 100 kin, not per km.

(ii.) *Tariff No.* 172 (i.). *Light mineral oils* (specific gravity below 0·730).—The reference ‖ to foot-note beginning "Conventional duty on paraffin oil" should be inserted against the words "10 per cent. *ad valorem*" in the third and fifth columns.

New Books.

ANNUAL STATEMENT OF TRADE OF THE UNITED KINGDOM WITH FOREIGN COUNTRIES AND BRITISH POSSESSIONS, 1905. Volume II. [Cd. 3022.] Wyman and Sons, Fetter Lane, E.C. Price 4s. 2d.

This blue book has been compiled at the Custom House from official documents, and contains abstract detailed tables of the trade of the United Kingdom with each country and at each port, together with some miscellaneous tables. The information covers the years 1901 to 1905.

English.—8*d.* each to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1*s.* each, to the Secretary of the Society.
French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (3e).

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

DECENNIAL INDEX, 1896-1905.

A Collective Index to the first fourteen volumes of the Journal (1882—1895), a volume of 550 pages, was published in 1899; a few copies of this are still left, price 10*s.* A second volume, embracing the period 1896—1905, is now in preparation, and will be ready for printing in 1906. It will contain both a subject matter and authors' names portion, and will be a volume of about 900 pages, uniform in size with the Journal. As the number of copies to be printed will depend on the number of applications from members, the Treasurer is prepared to receive subscriptions at the rate of 10*s.* each copy. A form of application for this purpose will shortly be issued.

CORRECTIONS FOR DECENNIAL INDEX.

Members are invited to call the attention of the Editor to any errors or omissions which they may have noticed in the Annual Indexes, 1896—1905, as soon as possible, in order that they may be put right in the Decennial Index.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps to the verification of addresses, on which the safe delivery of the Journal depends.

„ 13,714 (1905). Henry. Processes of cold dyeing. July 11.

„ 22,331 (1905). Johnson (Badische Anilin und Soda Fabrik). Production of stable dyeings. July 11.

„ 23,787 (1905). Brandt. Treating or impregnating textiles, paper, &c., with resins, fatty acids, and the like. July 18.

„ 25,602 (1905). Ellis (Chem. Fabr. von Heyden A.-G.). Manufacture of aldehyde hydrosulphite salts. July 11.

„ 2330 (1906). Summers. Preparation of vegetable fibre for spinning and other purposes. July 18.

„ 4533 (1906). Leishman. Waterproofing composition applicable also as a vehicle for pigments. July 18.

„ 8045 (1906). Soc. Franç. de la Viscose. Manufacture of artificial silk from viscose. July 11.

„ 12,517 (1906). Johnson (Badische Anilin und Soda Fabrik). Removal of colouring matter from dyed or coloured material. July 11.

„ 14,261 (1906). Kalle und Co. Dyeing and printing red on textile fibres. July 18.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 24,840A (1905). Clarke, Chapman and Co., and Robson. Absorbers for ammonia and other gases.* July 3.

„ 15,002. Miebach. Process of producing high-pressed ammonia vapours.* July 2.

„ 15,445. Carlson. Production of nitrogen compositions. [Swed. Appl., Feb. 28, 1906.]* July 6.

„ 15,590. Rinman. Manufacture of alumina compounds.* July 10.

„ 15,591. Jaeger. Manufacture of metal oxides.* July 10.

„ 15,753. Radcliffe. *See under* II.

„ 15,973. Bran and Van Oordt. Separation of beryllia from alumina and iron. [Ger. Appl., July 15, 1905.]* July 14.

[C.S.] 17,267 (1905). Langlands and O'Connor. Apparatus for making sulphate of ammonia. July 11.

„ 5901 (1906). Brünler. Oxidation of the nitrogen of the air, and conversion of the product into nitric acid or its salts. July 11.

„ 9419 (1906). Edwardes. Table salt. July 11.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 15,292. Chambers. Combined glass tank and pot furnace.* July 5.

„ 15,293. Chambers. Manufacture of glass.* July 5.

„ 15,539. Engelhorn. Treatment of corundum. July 9.

[C.S.] 5302 (1906). Pauls. Composition for making grinding tools. July 11.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 14,992. Wilson and Wilson. Process for making hydraulic cement. July 2.

„ 15,306. Latham. Utilisation of old plaster casts and other hydrated sulphate of lime, and apparatus therefor. July 5.

„ 15,553. Schougaard. Manufacture of artificial marble.* July 9.

„ 15,631. Altena. Apparatus for treating wood with preservative compositions. July 10.

„ 15,677. Thwaite. Burning or calcining calcareous and argillaceous and mineral substances in rotary furnaces or kilns. July 11.

„ 15,734. Collins. Manufacture of a refractory material. July 11.

„ 15,735. Collins. Manufacture of refractory materials. July 11.

„ 15,808. Simonsen. Cement mixture. July 12.

[C.S.] 6946 (1906). Morgan. Cement kilns. July 18.

„ 9006 (1906). Stowell. Bricks for fireproof and refractory purposes. July 18.

X.—METALLURGY.

[A.] 15,015. Bosshardt and Garda. Smelting furnaces.* July 2.

„ 15,384. MacIvor, Fradd, and The Metals Extraction Corporation, Ltd. Treatment of ores or ore products containing zinc. July 6.

„ 15,535. Plathner and Dorn. Tinning, leading, and soldering metals. [Ger. Appl., March 20, 1906.]* July 9.

„ 15,612. Callow. Compound flux for smelting metal. July 10.

„ 15,626. Colburn. Manufacture or treatment of iron or steel.* July 10.

„ 15,677. Thwaite. *See under* IX.

„ 15,722. Lake (Soc. L'Oxyhydrique Internat.). Soldering and brazing metals. July 11.

„ 15,818. Kaiser. *See under* XI.

[C.S.] 14,532 (1905). Kemper, Damhorst and Utke. Powder for application to patterns for sand moulding. July 18.

„ 20,961 (1905). Kemp. Smelting ores in blast furnaces. July 18.

„ 24,003 (1905). Lake (Parker). Art of producing metallic iridium. July 11.

„ 7451 (1906). Howatt. Mineral washing and separating apparatus. July 11.

„ 9799 (1906). Grönwall. Process for heating, smelting, or reducing materials. July 18.

„ 10,513 (1906). Siemens und Halske A.-G. Alloy for bearings or the like. July 11.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 14,971. Dickson. Insulating materials. July 2.
„ 15,727. Jungner. Primary galvanic elements. [Swed. Appl., July 12, 1905.]* July 11.
„ 15,759. Butterfield. Insulators and non-conducting material for electrical work. July 12.
„ 15,818. Kaiser. Process for obtaining metals from ores or furnace products in the electric furnace. [Ger. Appl., July 19, 1905.]* July 12.
[C.S.] 24,724 (1905). Clark (Darmstädter). Electrolytic manufacture of metal tubes and other bodies. July 18.
„ 11,498 (1906). Trunkhahn. Process for obtaining electrolytic metal deposits. July 18.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[C.S.] 14,294 (1905). Fell (Korndörfer). *See under* III.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(*A.*)—PIGMENTS, PAINTS.

[A.] 15,649. Boult (Schlegel). Oil-paints.* July 10.
[C.S.] 4533 (1906). Leishman. *See under* V.

(*B.*)—RESINS, VARNISHES.

[A.] 15,338. Justice (McKenzie). Method and apparatus for extracting turpentine and other products from wood.* July 5.
„ 15,341. Pickles. Composition of driers for paint, and drying materials for linseed and other drying oils and for varnish. July 6.
„ 15,838. Guittet. Manufacture of driers for paints, varnishes, and oils. July 12.
[C.S.] 8884 (1906). Sommer. Manufacture of mono-coloured linoleum. July 18.

(*C.*)—INDIA-RUBBER.

[A.] 15,638. Price. Refining or purifying india-rubber, gutta-percha, balata, and the like. July 10.

XIV.—TANNING, LEATHER, GLUE, SIZE, ETC.

[A.] 15,209. Boult (Stange). Manufacture of plastic and elastic substances and artificial leather therefrom. July 4.
„ 15,418. Sebastiano Bocciardo & Co. The tanning of hides. [Ger. Appl., July 6, 1905.]* July 6.
„ 15,648. Dufour. Treatment of tannic extracts.* July 10.
[C.S.] 26,517 (1905). Karle. Process for producing artificial leather. July 11.
„ 3107 (1906). Lerman, Schwartz and Pikos. *See under* IV.

XV.—MANURES, ETC.

[A.] 15,922. Brightmore. Production of fertilisers and the like. July 13.
„ 15,949. Earp-Thomas. Preparing and growing and distributing organisms which fix or gather atmospheric nitrogen. [U.S. Appl., Sept. 29, 1905.]* July 14.
[C.S.] 17,038 (1905). Furse. Method of obtaining manure and fuel from refuse. July 18.

XVI.—SUGAR, STARCH, GUM, ETC.

[A.] 15,974. Shaw. *See under* I.
[C.S.] 16,589 (1905). Boidin. *See under* XVII.
[C.S.] 22,425 (1905). König. Mechanical blueing apparatus for use in the treatment of sugar. July 11.
„ 10,278 (1906). Schüler. Centrifugal machines for clarifying and washing sugar and similar materials. July 11.

XVII.—BREWING, WINES, SPIRITS, ETC.

[A.] 15,179. Foll. Apparatus for drying yeast. July 4.
„ 15,254. Bailey. Production of sterilised or pasteurised non-deposit beer. July 5.
„ 15,966. Kubessa. Brewing process. [Ger. Appl., July 15, 1905.]* July 14.
[C.S.] 13,602 (1905). Soc. Jules, Jean, et Cie., and Raverat. Recovery of vapours of alcohol, pure or mixed with air, gases, moisture, or other volatile solvents. July 11.
„ 16,589 (1905). Boidin. Process for rendering the carbohydrates in general soluble, principally for grain distillation. July 18.
„ 26,274 (1905). Lee. Process of brewing. July 11.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(*A.*)—FOODS.

[A.] 15,173. Wurm. Method of treating milk.* July 4.

(*B.*)—SANITATION; WATER PURIFICATION.

[C.S.] 25,016 (1905). Stephenson. Apparatus for purifying water or other liquids. July 18.

XIX.—PAPER, PASTEBOARD, ETC.

[A.] 10,228A. Johnson (Badische Anilin* und Soda Fabrik). Manufacture of substances resembling celluloid.* July 6.
„ 15,001. Schmidt. Method of making partly transparent papers, and apparatus therefor.* July 2.
„ 15,068. Stock. Paper making machines. July 2.
„ 15,241. Mitchell. Treatment of paper and other surfaces. July 4.
„ 15,527. Eichmann. Production of sulphite cellulose from wood. July 9.
[C.S.] 23,787 (1905). Brandt. *See under* V.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENTIAL OILS, AND EXTRACTS.

[A.] 15,064. Wilhelm Anhalt Ges.m.b.H. Method of producing permanently clear tinctures. [Ger. Appl, Aug. 3, 1905.]* July 2.
„ 15,519 Newton (Bayer und Co.). Manufacture of dialkylbarbituric acids. July 9.
[C.S.] 15,515 (1905). Imray (Meister, Lucius, und Brüning). Manufacture of Δ_4-cyclogeranic acid and derivatives thereof. July 11.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[C.S.] 8911 (1905). Kelly and Bentham. Preparation and development of photographic plates, films, and the like. July 18.
„ 91 (1906). Deeks. Photographic printing. July 11.

XXII.—EXPLOSIVES, MATCHES, ETC.

[C.S.] 23,920. (1905) Wolfshohl. Apparatus for nitrating cotton or the like. July 18.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

[C.S.] 3417 (1906). Schatz. Apparatus for analysing gas. July 18.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 7287A. Johnson (Badische Anilin und Soda Fabrik). Manufacture of naphthalene derivatives.* July 6.

[C.S.] 22,736 (1905). Johnson (Kalle und Co.). Manufacture of organic compounds containing sulphur and of red colouring matter therefrom. July 11.

„ 3107 (1906). Lerman, Schwartz and Pikos. Manufacture of a black dye with by-products including a tanning agent or a second black dye. July 11.

„ 12,518 (1906). Johnson (Badische Anilin und Soda Fabrik). Manufacture of compounds of the anthracene series. July 18.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 15,133. Thiele, and Soc. Gén. de la Soie Artificielle Linkmeyer. Method of producing cellulose threads. July 3.

„ 15,160. Ribbert. Preparation of discharging resists under vat dyestuffs upon colours capable of discharge by hydrosulphites.* July 3.

„ 15,206. Newton (Bayer und Co.). Dyeing with sulphur dyestuffs. July 4.

„ 15,300. Paechtner. Dressing or sizing for yarns or other textiles.* July 5.

„ 15,618. Bonny and Pritchard. Method of preparing vegetable fibres.* July 10.

„ 15,629. Ellis (Merck). Impregnation of cotton fibres or cotton fabrics. July 10.

[C.S.] 13,580 (1905). Fell (Korndörfer). Process for oiling cotton and other vegetable fibres. July 11.

„ 13,714 (1905). Henry. Processes of cold dyeing. July 11.

„ 22,331 (1905). Johnson (Badische Anilin und Soda Fabrik). Production of stable dyeings. July 11.

„ 23,787 (1905). Brandt. Treating or impregnating textiles, paper, &c., with resins, fatty acids, and the like. July 18.

„ 25,602 (1905). Ellis (Chem. Fabr. von Heyden A.-G.). Manufacture of aldehyde hydrosulphite salts. July 11.

„ 2330 (1906). Summers. Preparation of vegetable fibre for spinning and other purposes. July 18.

„ 4533 (1906). Leishman. Waterproofing composition applicable also as a vehicle for pigments. July 18.

„ 8045 (1906). Soc. Franç. de la Viscose. Manufacture of artificial silk from viscose. July 11.

„ 12,517 (1906). Johnson (Badische Anilin und Soda Fabrik). Removal of colouring matter from dyed or coloured material. July 11.

„ 14,261 (1906). Kalle und Co. Dyeing and printing red on textile fibres. July 18.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 24,840A (1905). Clarke, Chapman and Co., and Robson. Absorbers for ammonia and other gases.* July 3.

„ 15,002. Miebach. Process of producing high-pressed ammonia vapours.* July 2.

„ 15,445. Carlson. Production of nitrogen compositions. [Swed. Appl., Feb. 28, 1906.]* July 6.

„ 15,590. Rinman. Manufacture of alumina compounds.* July 10.

„ 15,591. Jaeger. Manufacture of metal oxides.* July 10.

„ 15,753. Radcliffe. *See under* II.

Hon. Local Secretary and Treasurer:
T. U. Walton, Colonial Sugar Co., O'Connell Street, Sydney, N.S.W.

Yorkshire Section.

Chairman: F. W. Branson.

Vice-Chairman: Thorp Whitaker.

Committee:

J. E. Bedford.	J. Garfield.	H. R. Procter.
B. A. Burrell.	H. R. Hirst.	G. E. Scott-Smith.
E. M. Chaplin.	W. McD. Mackey.	G. W. Slatter.
S. M. Davies.	B. North.	A. Smithells.

Hon. Local Secretary and Treasurer:
T. Fairley, 17, East Parade, Leeds.

IV.—COLOURING MATTERS AND DYESTUFFS.

[A.] 7287A. Johnson (Badische Anilin und Soda Fabrik). Manufacture of naphthalene derivatives.* July 6.

[C.S.] 22,736 (1905). Johnson (Kalle und Co.). Manufacture of organic compounds containing sulphur and of red colouring matter therefrom. July 11.

„ 3107 (1906). Lerman, Schwartz and Pikos. Manufacture of a black dye with by-products including a tanning agent or a second black dye. July 11.

„ 12,518 (1906). Johnson (Badische Anilin und Soda Fabrik). Manufacture of compounds of the anthracene series. July 18.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

[A.] 15,133. Thiele, and Soc. Gén. de la Soie Artificielle Linkmeyer. Method of producing cellulose threads. July 3.

„ 15,160. Ribbert. Preparation of discharging resists under vat dyestuffs upon colours capable of discharge by hydrosulphites.* July 3.

„ 15,206. Newton (Bayer und Co.). Dyeing with sulphur dyestuffs. July 4.

„ 15,300. Paechtner. Dressing or sizing for yarns or other textiles.* July 5.

„ 15,618. Bonny and Pritchard. Method of preparing vegetable fibres.* July 10.

„ 15,629. Ellis (Merck). Impregnation of cotton fibres or cotton fabrics. July 10.

[C.S.] 13,580 (1905). Fell (Korndörfer). Process for oiling cotton and other vegetable fibres. July 11.

„ 13,714 (1905). Henry. Processes of cold dyeing. July 11.

„ 22,331 (1905). Johnson (Badische Anilin und Soda Fabrik). Production of stable dyeings. July 11.

„ 23,787 (1905). Brandt. Treating or impregnating textiles, paper, &c., with resins, fatty acids, and the like. July 18.

„ 25,602 (1905). Ellis (Chem. Fabr. von Heyden A.-G.). Manufacture of aldehyde hydrosulphite salts. July 11.

„ 2330 (1906). Summers. Preparation of vegetable fibre for spinning and other purposes. July 18.

„ 4533 (1906). Leishman. Waterproofing composition applicable also as a vehicle for pigments. July 18.

„ 8045 (1906). Soc. Franç. de la Viscose. Manufacture of artificial silk from viscose. July 11.

„ 12,517 (1906). Johnson (Badische Anilin und Soda Fabrik). Removal of colouring matter from dyed or coloured material. July 11.

„ 14,261 (1906). Kalle und Co. Dyeing and printing red on textile fibres. July 18.

VII.—ACIDS, ALKALIS, AND SALTS.

[A.] 24,840A (1905). Clarke, Chapman and Co., and Robson. Absorbers for ammonia and other gases.* July 3.

„ 15,002. Miebach. Process of producing high-pressed ammonia vapours.* July 2.

„ 15,445. Carlson. Production of nitrogen compositions. [Swed. Appl., Feb. 28, 1906.]* July 6.

„ 15,590. Rinman. Manufacture of alumina compounds.* July 10.

„ 15,591. Jaeger. Manufacture of metal oxides.* July 10.

„ 15,753. Radcliffe. *See under* II.

„ 15,973. Bran and Van Oordt. Separation of beryllia from alumina and iron. [Ger. Appl., July 15, 1905.]* July 14.

[C.S.] 17,267 (1905). Langlands and O'Connor. Apparatus for making sulphate of ammonia. July 11.

„ 5901 (1906). Brünler. Oxidation of the nitrogen of the air, and conversion of the product into nitric acid or its salts. July 11.

„ 9419 (1906). Edwardes. Table salt. July 11.

VIII.—GLASS, POTTERY, AND ENAMELS.

[A.] 15,292. Chambers. Combined glass tank and pot furnace.* July 5.

„ 15,293. Chambers. Manufacture of glass.* July 5.

„ 15,539. Engelhorn. Treatment of corundum. July 9.

[C.S.] 5302 (1906). Pauls. Composition for making grinding tools. July 11.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

[A.] 14,992. Wilson and Wilson. Process for making hydraulic cement. July 2.

„ 15,306. Latham. Utilisation of old plaster casts and other hydrated sulphate of lime, and apparatus therefor. July 5.

„ 15,553. Schougaard. Manufacture of artificial marble.* July 9.

„ 15,631. Altena. Apparatus for treating wood with preservative compositions. July 10.

„ 15,677. Thwaite. Burning or calcining calcareous and argillaceous and mineral substances in rotary furnaces or kilns. July 11.

„ 15,734. Collins. Manufacture of a refractory material. July 11.

„ 15,735. Collins. Manufacture of refractory materials. July 11.

„ 15,808. Simonsen. Cement mixture. July 12.

[C.S.] 6946 (1906). Morgan. Cement kilns. July 18.

„ 9006 (1906). Stowell. Bricks for fireproof and refractory purposes. July 18.

X.—METALLURGY.

[A.] 15,015. Bosshardt and Garda. Smelting furnaces.* July 2.

„ 15,384. MacIvor, Fradd, and The Metals Extraction Corporation, Ltd. Treatment of ores or ore products containing zinc. July 6.

„ 15,535. Plathner and Dorn. Tinning, leading, and soldering metals. [Ger. Appl., March 20, 1906.]* July 9.

„ 15,612. Callow. Compound flux for smelting metal. July 10.

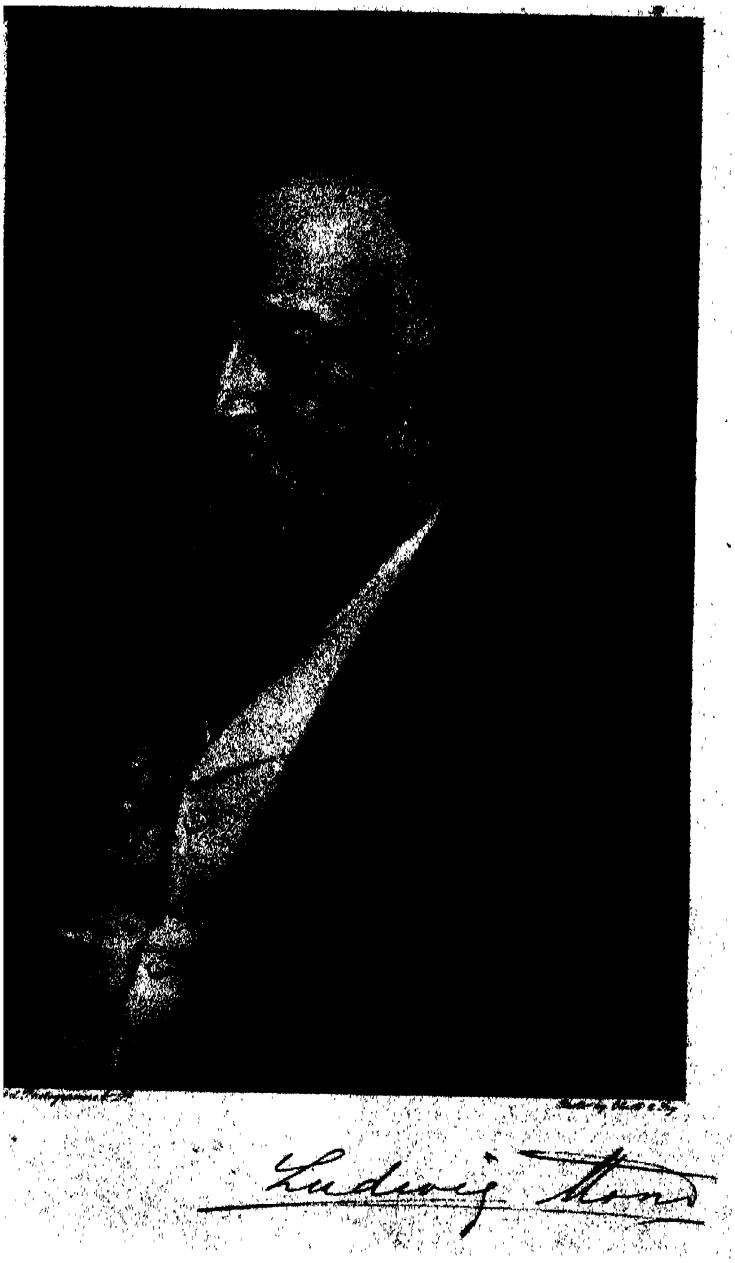
„ 15,626. Colburn. Manufacture or treatment of iron or steel.* July 10.

„ 15,677. Thwaite. *See under* IX.

„ 15,722. Lake (Soc. L'Oxyhydrique Internat.). Soldering and brazing metals. July 11.

„ 15,818. Kaiser. *See under* XI.

[C.S.] 14,532 (1905). Kemper, Damhorst and Utke. Powder for application to patterns for sand moulding. July 18.



„ 20,961 (1905). Kemp. Smelting ores in blast furnaces. July 18.

„ 24,003 (1905). Lake (Parker). Art of producing metallic iridium. July 11.

„ 7451 (1906). Howatt. Mineral washing and separating apparatus. July 11.

„ 9799 (1906). Grönwall. Process for heating, smelting, or reducing materials. July 18.

„ 10,513 (1906). Siemens und Halske A.-G. Alloy for bearings or the like. July 11.

Ludwig Mond

Change of Style.

His Majesty has been pleased to confer the honour of knighthood on Dr. William Henry Perkin, F.R.S.

PROCEEDINGS
OF THE
TWENTY-FIFTH ANNUAL MEETING.

MANCHESTER;

WEDNESDAY, JULY 11TH, 1906.

The Twenty-fifth Annual General Meeting of the Society was held at the Municipal School of Technology, Manchester, on Wednesday, July 11th, the President, Dr. Edw. Divers, F.R.S., being in the chair.

Among those present were Mr. Eustace Carey (President-Elect), Dr. L. Baekeland, Sir W. H. Bailey, Mr. John Brock, Mr. W. W. Butler, Dr. J. T. Conroy, Mr. G. M. Davidson, Dr. C. Dreyfus, Mr. Thos. Fairley, Dr. C. E. Fawsitt, Prof. P. F. Frankland, F.R.S., Prof. A. G. Green, Prof. C. E. Groves, F.R.S., Mr. Oscar Guttmann, Mr. Samuel Hall, Mr. D. H. Hacking, Mr. D. Roscoe Hardwick, Mr. H. Hemingway, Mr. Julius Hübner, Dr. D. B. Hewitt, Mr. J. M. Irving, Prof. W. R. Lang, Mr. Ivan Levinstein, Dr. J. Lewkowitsch, Dr. K. E. Markel, Mr. T. D. Morson, Mr. J. Worthing, Mr. F. R. O'Shaughnessy, Mr. David Perry, Prof. W. J. Pope, F.R.S., Sir Boverton Redwood, Mr. J. H. Reynolds (Principal Clerk of Manchester), Sir H. E. Roscoe, F.R.S., Mr. F. Scudder, Mr. Watson Smith, Mr. E. R. Taylor, Mr. H. L. Terry, and Mr. Thos. Tyrer.

There was a large attendance of members.

The PRESIDENT read a letter received from the Chairman of the Manchester Section (Dr. G. H. Bailey), expressing regret at his inability to be present, and communicating the hearty welcome which Manchester desired to express to the Society on visiting that city for its twenty-fifth annual meeting.

Dr. HEWITT stated that he had been asked by the Manchester Section to express their hearty welcome to the members on that, the twenty-fifth meeting of the Society. The Society was initiated in Manchester, and he saw on the platform two of those who were present when the Society was inaugurated, Sir Henry Roscoe and Mr. Eustace Carey. He well remembered the long discussion which they had, as to what would be a suitable name for the Society. He was very glad to welcome to Manchester that large national Society, which had now branches not only on this side but abroad. He was much interested in the formation of the American Sections, and was glad to welcome their American friends. He had great pleasure in welcoming the Society on that, the twenty-fifth anniversary of the Society, to Manchester.

The PRESIDENT, addressing Dr. Hewitt, said that, on behalf of the Society, he returned very hearty thanks for the cordial way in which they (of Manchester) had provided the members hospitality. It was a very great pleasure to him to note the active part which Manchester had taken in inaugurating that Society. He proposed a vote of condolence with the Chairman of the section, Dr. Bailey, expressing at the same time their gratification at knowing that he was making rapid recovery to full health again. He suggested that a message be sent saying how much they missed him, and that they were very glad to know he was through with his illness.

The suggestion was approved, and the Secretary was instructed to send such a message to Dr. Bailey.

The PRESIDENT then called upon the Secretary to read the Minutes of the last meeting.

The General Secretary, Mr. CHARLES G. CRESSWELL, read the Minutes of the previous meeting, and of the extraordinary general meeting held on March 27th, with the object of considering and adopting, if approved, a resolution :—

"That it is desirable that the Society of Chemical "Industry, as now existing, should be incorporated "under and subject to the grant of a Royal Charter, "and that the Council be, and hereby is authorised "to take all necessary steps to procure the grant of a "Royal Charter of Incorporation."

The Minutes were confirmed.

The PRESIDENT read letters, expressing regret at their inability to be present at the meeting, from Mr. Forbes Carpenter, Mr. N. H. Martin, Mr. A. Gordon Salamon, and Mr. Chas. Wightman.

NOMINATIONS TO THE COUNCIL.

The PRESIDENT read the list of the new Council, as follows :—

LIST OF COUNCIL, 1906–1907.

President : Eustace Carey.

Vice-Presidents :

Dr. L. Baekeland.	Dr. E. G. Love.
J. Carter Bell.	N. H. Martin.
Dr. Virgil Coblents.	Dr. Wm. H. Nichols.
Dr. Edw. Divers, F.R.S.	Sir Wm. Ramsay, K.C.B., F.R.S.
David Howard.	A. Gordon Salamon.
Dr. J. Lewkowitsch.	Chas. Wightman.

Ordinary Members of Council.

Dr. J. T. Dunn.	Sir Boverton Redwood.
Oscar Guttmann.	Walter F. Reid.
E. Grant Hooper.	Dr. F. J. Smale.
Prof. W. R. Lang.	Thos. Tyrer.
A. R. Ling.	Sir Thomas Wardle.
Dr. K. E. Markel.	R. C. Woodcock.

Sectional Chairmen and Secretaries :

BIRMINGHAM.
Prof. Percy F. Frankland, F.R.S. | F. B. O'Shaughnessy.

CANADIAN.
Prof. W. Hodgson Ellis. | Alfred Burton.

LIVERPOOL.
Dr. Jas. T. Conroy. | W. Roscoe Hardwick.

LONDON.
R. J. Friswell. | Julian L. Baker.

MANCHESTER.
Dr. G. H. Bailey. | Julius Hübner.

NEWCASTLE.
Prof. H. Louis. | Dr. F. C. Garrett.

NEW ENGLAND.
Henry Howard. | Alan A. Claflin.

NEW YORK.
Geo. C. Stone. | Dr. H. Schweitzer.

NOTTINGHAM.
J. M. C. Paton. | R. R. Tatlock.

SCOTTISH.
J. S. McArthur. | Dr. Chas. E. Fawsitt.

SYDNEY, N.S.W.
Dr. R. Greig Smith. | E. V. Walton.

YORKSHIRE.
F. W. Branson. | Thomas Fairley.

Honorary Treasurer.
Samuel Hall, East London Soap Works, Bow, E.

Honorary Foreign Secretary :
Dr. Ludwig Mond, F.R.S.

General Secretary : Charles G. Cresswell, 50, Palace Chambers, 9, Bridge Street, Westminster, S.W.

Telegraphic Address : 50, Palatable, London.

Telephone Number : 7316, Victoria.

The SECRETARY read the Report of the Council of the Society for the past year, as follows :—

REPORT OF COUNCIL.

The number of members on the register is 4,442, as compared with 4,326 at the last Annual Meeting. During the year 371 members have been elected as compared with 452 last year; the losses have been 255 as against 260, and there have been 35 deaths as compared with 41 last year.

The names of those who have died are : Robt. Bardsley, C. A. Bartsch, Percy Bateson, Thos. Christy, Aug. Clark, F. G. Claudet, A. N. Crosskey, Jas. Donald, Jas. Duncan, H. S. Elworthy, R. W. S. Griffith, Dr. W. Hanuaford, G. H. Hurst, Dr. Karl Kellner, Jos. Leese, Dr. J. R. Littlewood, F. Maxwell Lyte, A. R. Meyer, Jas. P. Muir, S. Newgass, W. J. Orsman, J. H. Osmond, L. W. Redpath,

Thos. Royle, D. Russell, Howard P. Ryland, Charles Sevin, Prof. H. Sprengel, F.R.S., Dr. Wm. S. Squire, Robt. Taubman, Jas. Davis Taylor, Sir Charles Tennant, Bart., M. A. Whichelo, W. Watson Will, and Harvey L. Williams.

The Hon. Treasurer's financial report was issued in the Journal for June 30th, and will be laid before the meeting.

The Journal for 1905 numbered 1,334 pages, equal to 55·6 pages for each issue, as compared with 52·2 in 1904. During the past session 85 original papers, with discussions, have appeared in the Journal as compared with 92 in the previous session. Of 24 papers returned to authors by the Publication Committee for recasting, amendment, or condensation, 18 have been published and three have been withdrawn. Thirteen papers and communications have been refused. Mr. T. F. Burton has been appointed Indexer of the Journal in place of Mr. Renaut who has resigned.

Mr. David Howard and Mr. Thomas Tyrer have been nominated by the Council to succeed Mr. Walter F. Reid and Mr. R. Forbes Carpenter as the Society's representatives on the Governing Body of the National Physical Laboratory. Mr. David Howard has since been placed upon the Executive Committee of the Laboratory.

Some discussion took place between the Council and the Governing Body of the National Physical Laboratory with regard to work invited by the Laboratory which came within the scope of the practising chemist; and certain words in a letter from Lord Rayleigh to the President of the Society of Public Analysts, as well as in the Test Pamphlet published by authority, appeared to indicate that this competition with private enterprise might continue. After some correspondence, the Executive Committee promised to modify the wording of the Test Pamphlet, and gave satisfactory assurances in regard to the work of the National Physical Laboratory. Copies of the correspondence were sent to the Institute of Chemistry and the Society of Public Analysts.

It has been decided to petition H.M. the King to grant to the Society a Royal Charter of Incorporation. A requisition, in accordance with By-Law 40, asking the Council to convene an Extraordinary General Meeting of the Society to consider the matter, was presented in December last, and on March 27th the meeting was held at the House of the Society of Arts, at which it was unanimously resolved:—"That it is desirable that the Society of Chemical Industry, as now existing, should be incorporated under and subject to the grant of a Royal Charter, and that the Council be and hereby is authorised to take all necessary steps to procure the grant of a Royal Charter of Incorporation."

On the recommendation of the British Joint Organising Committee, the Council concurred in the opinion that the International Congress of Applied Chemistry should be invited to hold its seventh meeting in London in 1909, and undertook the preliminary arrangements connected with the giving of the invitation in Rome. At the closing meeting of the Congress Dr. Ludwig Mond gave the invitation, and was supported by Prof. W. A. Tilden on behalf of the British Government, Dr. Edw. Divers on behalf of this Society, and Prof. R. Meldola on behalf of the Chemical Society. The invitation was unanimously accepted, Sir William Ramsay was elected President, Sir Henry Roscoe, Hon. President, and the Joint Organising Committee already formed was made the Organising Committee for the next Congress.

A committee has been formed to celebrate the Jubilee of Dr. W. H. Perkin's discovery of the first aniline dye-stuff, and all the members of this Society have been invited to take part in the movement. It is proposed to present Dr. Perkin with his portrait, to be retained by him during his lifetime and afterwards to become the property of the nation, and to place his bust in the rooms of the Chemical Society.

The Council has been able to render some assistance to the Board of Trade in the negotiations in regard to the new Spanish and Portuguese tariffs.

There is every probability that the pledges on the subject of Industrial Alcohol given by the late Chancellor of the Exchequer will be carried out by his successor.

A committee of the Society is at present engaged in collecting evidence to be laid before the Royal Commission on Canals and Waterways.

Representatives of the Society were appointed to join a deputation which waited on the President of the Board of Trade on April 9th to urge upon his attention the subject of Patent Law Amendment, and, in particular, the necessity of putting an end to protection for inventions which are only worked abroad.

In order better to enable members abroad to take part in the elections of the Council, a few simple amendments in the By-Laws are proposed, whereby members will have a little more time to return their Ballot papers.

The medal has on this occasion been awarded to Dr. Ludwig Mond, F.R.S., for his conspicuous services to Applied Chemistry in all the three departments for which the medal was established, *viz.*, his researches, discoveries, and improvements in processes.

Mr. John Brock formally moved the adoption of the Report.

Mr. C. E. Groves said he had great pleasure in seconding the Report, and must, at the same time, congratulate the Council and their fellow members on trying to effect their incorporation as a Royal Society, which would no doubt be carried out.

The Report was adopted.

The Hon. Treasurer (Mr. Samuel Hall) said that in the Journal of June 30th, on page 565, there appeared a statement of last year's working, as nearly correct as it was possible to make it. In the income there had been an increase of £220 from members' subscriptions; entrance fees gave an increase of £35, the total of entrance fees and life composition fees being £486. This was not reckoned as available income. £500 of such money had been invested, and £485 had been received on account of income from investments, being £42 more than in 1904. £237 had been received from advertisements, and £491 from sales, making the working income £6254. As regards expenditure, £1160 extra had been spent in publishing and postage. This, with the Editorial work, which was as before, made the total for publishing the Journal £3679. Two new Sections had been added during the year. Birmingham, an old Section which had fallen out, had been revived, and a vigorous New England Section had been formed. The Sectional expenses had, therefore, a tendency to increase. They, and the Annual Meeting expenses, amounted to £860, being only £24 less than in 1904, which was an exceptionally heavy year. The remaining working expenditure was a little over £1000, £30 in excess of 1904. Towards the Decennial Index £91 had been paid; it was hoped this would be ready early in 1907; it involved a very considerable cost for compilation, and an equally large cost for printing. It would be a very valuable work, and, when within measurable distance of completion, notice would be sent out asking those who wished for copies to send their names and subscriptions, that an estimate might be formed of the number of copies required. Fresh arrangements had been made for indexing the yearly volume, at a less cost, while making the index ready earlier in the year. Mr. Burton had been appointed indexer of the Journal in place of Mr. Renaut, who had resigned.

At this point the Right Honourable James Herbert Thewlis, Lord Mayor of Manchester, arrived, and took his seat on the platform.

Mr. Hall, proceeding, said the final position, the excess of income over expenditure, was a balance of £423 to the good. This was not much, and was £60 less than the dividends from their investments. Careful economy would be necessary, and the Council were considering if they could not increase the income by advertisements. Arrangements had been made for cheques on American banks to be sent direct to the Treasurer. This should be a decided convenience to members on the other side, instead of their having to obtain paper payable in England, and it was hoped it might lead to an increased number of members. The balance sheet to the 31st December, 1905, would be found on page 566 of the Journal, and the receipts and expenditure during the year. That was

the real balance sheet. They had been able to invest £1,000 during the year, and to carry forward £1,100 in cash for the work of the Society this year. All accumulations were invested in first-class securities, and in the name of three trustees.

Mr. THOMAS TYRER moved that a vote of thanks be given to the Hon. Treasurer. He called attention to the narrowness of the margin between the revenue and the expenditure. Mr. Hall had, he said, referred to the responsibility of the Council with regard to economy, but he did not hear that he had referred to the duties of members who valued their privileges in the shape of the JOURNAL. Never mind, Mr. Tyrer said, what was called in business "touting," let them "tout" in a good cause. He ventured to say their duty was to support the Society, and increase the membership and revenue. He proposed a vote of thanks to the Hon. Treasurer. for the work which he had done for them.

Dr. L. BAEKELAND seconded, and the vote was passed with enthusiasm.

The PRESIDENT said that they were now honoured by the presence of the Lord Mayor, who had kindly come to address them on the subject of their visit.

The LORD MAYOR said that he knew they had a programme before them which would be, at any rate, an exhausting tax, not only on their physical endurance, but on some other aspects of their physical capacities, and therefore he would only detain them a moment. He did so with much pleasure that morning, because during the year of his tenure of office as Lord Mayor there had been visits paid to the city by members of societies and members of congresses of various classes of the community, and it had been his pleasure to receive a good number, but of none could he say that his pleasure had been greater than in receiving that morning, on behalf of the city, the members of the Society of Chemical Industry. To begin with, he rather liked the description of their Society as one of industry, and as one of chemical industry. They, probably, above and beyond all others, combined a double capacity. In the first place, the development and industrial application of their researches would make for themselves, he was going to say, large fortunes; many of them did, and were heartily welcome to them and deserved them. In the second place, it was scarcely possible for them to benefit themselves without at the same time benefiting the community. That was the strongest feature of their Society—they benefited society by the tangible means which contributed to the development of their own fortunes. If he might be so rude as to illustrate what he meant, by the case of a gentleman who seconded the last resolution, he had been identified with "Velox," and benefited himself to an enormous extent, but he could not do that without benefiting others at the same time. He (the Lord Mayor) was very glad that it fell to him in his year of office to welcome their splendid Society of Chemical Industry. He trusted their stay in the city might be pleasant, and that the weather might be all that they could wish.

The PRESIDENT, addressing the Lord Mayor, said it fell to him, on behalf of that Society, to express to him their most cordial thanks for the reception which the city of Manchester had given them on that occasion, and to assure him that all were interested in the city of Manchester in respect of its chemical industries. In the old days, the Society owed very much to Manchester. The meeting for forming it took place in Manchester. They thanked the Lord Mayor very heartily for coming there that day to offer that welcome on behalf of the city.

The Lord Mayor now retired.

The PRESIDENT, before proceeding to deliver his presidential Address, expressed the pleasure which it was to him to welcome many of those who were before them. They had to welcome that day Sir Henry Roscoe; Mr. Brock, another founder of the Society, and another of those men on whom so much of the success of the Society had depended; Dr. Hewitt he had already referred to; and there were others, of whom he might name Mr. Tyrer, but there was one among them all that he was particularly desirous of referring to, and that was their President-elect, Mr. Eustace Carey. He now took the opportunity of expressing to him the very great satisfaction they had in the prospect before them of sitting under him for the next year to come, as their President. He called upon Mr. Carey to respond, on behalf of the founders and on his own behalf, in connection with the office they had conferred on him. (Applause.)

Mr. EUSTACE CAREY, who was cordially greeted, said he knew they were as anxious as himself that the President should deliver his Address at the earliest possible moment; he must, however, obey that command by rising and saying how greatly he appreciated the honour they had conferred on him that day, an honour he never had the slightest idea was coming along his way until he had a word from his kind friend Mr. Tyrer. Whatever was coming during the next year, he could only promise one thing, and that was, that as far as his small ability went, anything that he could do to promote the interests of the Society should be done. With regard to the founders of the Society, they were all delighted to see their beloved first President there, to whom he (Mr. Carey) thought they might say that that Society owed more than to any other man. The President had mentioned others: Dr. Mond, Mr. E. K. Muspratt, and Mr. Brunner were invited to attend the first meeting; Dr. Mond invited Manchester men like Dr. Schunck and others, and then Sir Henry Roscoe invited men in London, and the result they saw that day in one of the largest societies that existed. He again thanked the members for the honour they had conferred upon him, and concluded by expressing the hope that at the end of the year they would not be disappointed.

PRESIDENT'S ADDRESS.

The PRESIDENT then read his Address, the full text of which was as follows:—

THE SOCIETY OF CHEMICAL INDUSTRY.

The time and place of this meeting offer a fitting opportunity to take a retrospect of the life of the Society of Chemical Industry. In accordance with the approved custom of reviewing events, when some self-imposed task of public utility has been going on uninterruptedly for a quarter-century, this should be the day on which progress is to be reported, for this assemblage of members constitutes the twenty-fifth Annual General Meeting of the Society. No place more appropriate than Manchester could have been chosen in which to issue that report of progress. It was in Manchester that much of the work was carried out which led up to the formation of the Society of Chemical Industry, and it was here, for six years, that the Journal of the Society was printed and published. Not only is Mr. Watson Smith, who has edited our Journal throughout its existence, a former member of the teaching staff of what was then the Owens' College of Manchester, but Sir Henry Roscoe, the distinguished man who took so large a part in bringing the Society into existence, who was the first President of the Society, and the first chairman of its Manchester Section, was for nearly forty years associated with Manchester, first, as Professor of Chemistry in the Owens' College, and afterwards as one of its Members of Parliament. Only a few years ago, for two years in succession, another President of the Society, Mr. Ivan Levinstein, was chosen from Manchester, and the meeting to-day is the fourth Annual Meeting of the Society that has been held in Manchester.

The Chemical Society, founded in 1841, was 36 years old when the Institute of Chemistry was incorporated (1877), and 40 years old when the Society of Chemical Industry was founded, and the younger bodies have become very successful, without in the least affecting unfavourably the increasing rate of growth of the parent Chemical Society. This fact makes it certain that there is no rivalry in the purposes of these Societies. But that does not lessen the interest of an enquiry into the distinctness

of their provinces from each other, not perhaps so well appreciated as it should be. Manifestly, the titles of these Societies only imperfectly indicate what differences there may be, and not altogether satisfactory is the information as to the nature of these differences which is to be obtained by reference to their articles of Association.

First, let us consider the titles. To everyone, such a title as Law Society or Natural History Society conveys correctly the notion of a society formed for doing something in connection with law or natural history—promoting knowledge of it, as a matter of fact. To call a Law Society a Legal Society would be felt to be the substitution of a puzzling title for the correct one. So much objection is not, however, felt to the use of the title, Historical Society, although History Society would be preferable, because free from the ambiguity, if not oddity, of calling a society, historical. The titles, Chemical Society, Physical Society, Electrical Society, have, however, been accepted without misgiving, and are now not to be changed, even though they cannot be defended. But, at least, we see that the meaning is not the impossible one, that a society is chemical, but that it is a Chemistry Society, a Society which is concerned in some way with chemistry, presumably with its advancement. Between the titles, Chemical Society and Institute of Chemistry, no sufficient distinction can be drawn, since, as here used, "institute" can scarcely be differentiated from "society" to any useful extent.

The titles, "Institute of Chemistry" and "Society of Chemical Industry," are alike to be condemned, with that of "Society of Arts," on the ground that a society is of persons, and not of arts or sciences or anything else, as is seen illustrated in the titles, "Institution of Civil Engineers," of "Naval Architects," &c., "Society of Public Analysts," &c. The founders of the Institute of Chemistry would indeed have correctly named it, "The Institute of Professional Chemists," had it not been for the fact that anyone who is not registered as a "pharmaceutical chemist" or a "chemist and druggist" is punishable with fine should he style himself a "chemist." In the case, too, of the Society of Chemical Industry, such titles as "Society of Chemical Engineers" and "Society of Technical Chemists" had been suggested for it. That neither was adopted was due mainly to the recognition, that it was not sufficiently comprehensive. The excuse for giving it the title, "Society of Chemical Industry," is that this title came into existence as an abbreviation of "Society for the Advancement of Chemical Industry," an earlier title only to be objected to on account of its length, and for a defect common to it and the term, "chemistry," similarly used. It is not for the promotion, except indirectly, of chemical or any other industry that the one society has been formed, or for the promotion of chemistry that the other has been formed. It is for the promotion of knowledge of the ways in which the science of chemistry can be utilised in the industrial arts, that is, in the arts which minister to the needs and desires of mankind, that the one Society exists, and for the advancement of the science of chemistry that the other Society exists. This view of the matter is justified by the fact, that the extended title of the Royal Society is that of being for improving natural knowledge, and that the title of the British Association is that of being for the advancement of science. We are apt to forget that there is chemistry itself, and that there is the science of chemistry: chemistry being the change of substances into other substances, whilst its science is the knowledge of chemical phenomena and their relations of interdependence.

Having seen that the titles, when liberally interpreted, indicate a sharp delimitation of the provinces of the Society of Chemical Industry and the Chemical Society, we may look into the Charters or Articles of Association of the three Societies for fuller information. According to the Charter of the Institute of Chemistry, the object of that Society is to attest by the certificate given to each of its Fellows and Associates that he was admitted into the Society only after he had proved himself qualified to advise concerning the applications of chemistry to the industrial arts. Its object, therefore, marks it off very distinctly from either the Chemical Society (so nearly the same in title) or the Society of Chemical Industry. There must not, in justice, be overlooked, however, the beneficial influence which the Institute of Chemistry exerts upon the advancement of the science of chemistry, and of the knowledge of the applicability of that science to the service of man, by making the attainment of efficiency in applying the science of chemistry to the development of the arts a condition for receiving its fellowship.

In the preamble to the Charter of the Chemical Society, confirmation is to be found of the correctness of the reading of its title which was just now set forth. It is stated in its charter that the Chemical Society was established for the general advancement of chemical science, and that it had till then pursued that object by having discoveries brought under discussion and the results made known to the public. But matters become rather complicated by the circumstance that in the amplification of this statement it is said that the object of the Society is the "advancement of chemical science, as intimately connected with the prosperity of the manufactures of the United Kingdom, many of which mainly depend on the application of chemical principles and discoveries for their beneficial development, and for a more extended and economical application of the industrial resources and sanatory conditions of the community." This may look very like a definition of the object of a society of chemical industry. But it is not really so, and these words, giving a reason why the real object of the Chemical Society should be promoted by the grant of a Royal Charter, only express now the need which was then felt, if the application for the Charter was to be successful, of pleading the commercial utility of that object to an audience little alive to the value of the cultivation of science for its own sake. It has always been fully recognised that the motive of its utility is not the motive for doing most of the work brought before the Chemical Society, but a still higher one, little understood by the world at large, and therefore hardly to be serviceably expressed in the petition for a charter. Very few papers on chemistry in relation to chemical industry have appeared in the Journal of the Chemical Society, and on the occasion when Henry Deacon, describing himself, with a purpose, as "Alkali Manufacturer, Widnes," lectured to the Society, in 1872, on the application of physics and chemistry to explain the catalytic conversion of hydrochloric acid and atmospheric oxygen into chlorine and water, he availed himself of the occasion at the end of the lecture to appeal to the Society to try to attract manufacturers and technological chemists to its meetings by giving them opportunities to read papers on chemistry applied to the arts. Nothing came of the appeal, the Council of the Society apparently recognising the impracticability of admitting such papers into its transactions.

But the objection may be made that the Chemical Society publishes abstracts of papers on chemistry in connection with mineralogy, agriculture, and physiology, and that it did, until April, 1886, publish abstracts on chemistry as used in the arts, and still does so on chemistry used in identifying substances ("analytical chemistry"), thus showing its activity in connection with the applications of chemistry. The answer to this objection is simple. The Chemical Society helps to spread knowledge of the applications of chemistry only as a means to advance the science of chemistry, just as knowledge of the progress of the science of chemistry is seen to be all-important to him who would successfully apply chemical science to the industrial arts.

The Society of Chemical Industry has not yet got a Charter of Incorporation, but in its by-laws the specific object of its establishment is stated to be "to advance applied chemistry in all its branches." In connection with this definition of the object of the Society, it is to be mentioned that "Society of Applied Chemistry" was a title suggested for it before its present one was decided upon, just as recently there was the meeting in Rome, which called itself the Sixth International Congress of Applied Chemistry. The terms "applied chemistry," "applied physics," "applied mathematics," "applied mechanics," and the like, are too firmly planted in the language of technology to leave anyone much hope.

that they will, within a reasonable time, fall into disuse. Nevertheless, the propriety of using such terms must be seriously called in question. In the first place, we have to remember that there is only one science of chemistry, one science of mathematics, and so forth, and certainly in the term, "applied chemistry," by chemistry is meant the science of chemistry. Whether "applied" or not, whether called "analytical," "practical," or anything else, chemistry remains one and the same science still. It follows, almost obviously, at least it does so on reflection, that by "applied" chemistry is not meant chemistry at all, and that it is not an object, at least not a direct object, of the Society of Chemical Industry to advance the science of chemistry. "Applied chemistry" signifies, not chemistry itself, but its applications—it might be to anything; but, by convention, applications to the useful arts and manufactures. The Society of Chemical Industry concerns itself with the applicability, conceived only or verified, as the case may be, of the science of chemistry to the arts, and its object is to advance the knowledge of how and when or where to apply the science of chemistry in manufactures and other undertakings. In brief, its object is to advance the scientific knowledge of chemical technology.

In its by-laws other objects of the establishment of the Society are given, but on examination these so-called objects prove to be nothing but ways and means to be employed in the furtherance of the true object of the Society. As there stated, the second of these objects is said to be to afford its "members opportunities for the interchange of ideas with respect to improvements in the various chemical industries, and for the discussion of all matters bearing upon the practice of applied chemistry." To the first part of this statement, the suspicion of hollowness seems to cling. There are those, indeed, numerous enough, who will give to the world their ideas how particular industries might be improved, and we can receive these ideas for what they are worth. But few ideas which can be acted upon with good promise of success are ever given thus generously to the world, instead of being worked out under the direction of those who have conceived them. Whether or not that be the case, it is not to be supposed that the Society of Chemical Industry endeavours to cultivate this publication of ideas. Then, too, the words quoted, "practice of applied chemistry," will also be felt to have been not well chosen, especially if the comments just now made upon the term, "applied chemistry," meet with approval. Even the substitution of "practice of applying chemistry to the arts," or of "practice of chemical technology," either of which would be an improvement, would not make things right, for part of the difficulty lies in the use of the term "practice." It is not wanted to express what is intended, and it may convey what is not meant. It has elsewhere an accepted professional meaning and may therefore here suggest that the province of the Society of Chemical Industry trenches upon that of the Institute of Chemistry. The third object is said to be "to publish information upon" improvements, and so forth.

It is now suggested that the object of the Society, as understood by the founders, is fully and more definitely expressed as being "To promote in every way the use of the knowledge of how the science of chemistry may be successfully applied to manufactures and other industries." To attain that object, the Society, through its Council and Committees, endeavours to increase and diffuse that knowledge, and to lessen difficulties in the making full use of it, firstly, by organising meetings of its members to receive and discuss communications made to it concerning what purports to be an enlargement of that knowledge; secondly, by publishing a journal of the proceedings of the Society, together with abstracts of letters patent, and other publications concerning such advances in chemistry as seem likely to react upon industry, and concerning proposed or actual changes in the applications of chemistry to the arts; thirdly, by influencing legislation when it affects the development of chemical industries; and, fourthly, by doing such other things, as acquiring and disposing of property, which may be conducive to the attainment of its object.

Some possible misconception of the sense of this phrasing of the object of the Society may be here anticipated and provided for. Men interested and engaged in the pursuit of a chemical industry too often attach a meaning to the word science, which makes them ready to exclaim, when they meet it, that what is wanted is a "practical" knowledge, compared with which "scientific" knowledge is of small account. They attach a contemptuous common meaning to scientific knowledge, associating and even confounding it with what is known as "book" knowledge, a verbal "so-it-is-said" knowledge, included along with other things in the equipment of the well-read and well-informed man. Such knowledge need not be, and usually is not real knowledge at all. It is possible for a man to be textually familiar with the contents of a large treatise on chemistry, and yet be wanting in the qualification of a chemist. Only the practical chemist, to use the current term, can indeed be a chemist, can possess a scientific knowledge of chemistry. But not a few "practical chemists" have been, in the past and perhaps are still to-day, almost without scientific knowledge, and without, therefore, any true claim to be a chemist. Their practical knowledge is mere experience unenlightened by science. There may be a pile of it, but all of it will be without cohesion, unproductive and unprogressive. Apart from his craftsmanship, which may be an invaluable acquisition, his so-called practical knowledge is not worth consideration. To convert the experience of the practical man, to convert in fact any experience, into that real, trustworthy knowledge which is the true scientific knowledge, the matter of that experience must be analysed and resolved into phenomena or events standing or occurring in definite interdependent relations with each other, relations ascertained quantitatively to be such by trained observation and experiment. Only those who handle facts in that way have knowledge of them available for development and progress, and only among practical men, those who do handle facts, can those who have scientific knowledge be found. There is no science not resting on art, practice, experience. The concern of the Society of Chemical Industry is that chemical industries shall be carried out with scientific knowledge, instead of being dependent solely, as they have been and often are, upon that knowledge which is mere experience.

When "science" and "theory" are given their true sense, the contrasts, "science and practice," "theory and practice" lose all the point they are supposed to have. Theory is the quintessence of science, but, unfortunately, much base coin passes for theory. The utterers of these base coin are nearly always the unscientific practical men.

To repeat, all science is practical; the making and extending of science is art, and, obviously, so are its applications, which, when the science applied is chemistry, are the concern of the Society of Chemical Industry. In that familiar collocation, "science and art," we have, according to the dictionary, "art" used as being opposed to "science." This, then, is but another form of the disjunction of "practice" from "science" or "theory"—pseudo-science, pseudo-theory, that is—to which reference has just been made. But the phrase, "science and art," merits more consideration. If "art" is taken here to signify the fine arts, then indeed a striking contrast is offered by the collocation, "art" being the outcome of the emotions, of the æsthetic analysis and estimate of natural phenomena, and "science" being the outcome of the reason, of the intellectual analysis and measure of natural phenomena. But if "art" is taken in its simple sense of being ability to apply the faculties of mind and body to the achievement of a desired end, then any coordination of the terms "science" and "art" ceases to be evident, and their collocation loses significance.

That all science is practical and comes through art is a proposition least evident, probably, when it relates to mathematics, because the science of mathematics deals with such pure abstractions. But on consideration it will be seen how great must be the mental activity when some advance is being made in this science, activity so elaborate as to be only effectively exercised through the external medium of a calculus of operations. The man who merely "reads" mathematics, without acquiring the

mental aptitude or skill to extend either the science or a knowledge of its applicability in aid of other sciences, is no mathematician, though there are many such vain manipulators of symbols who pass as such. Coming to our own science of chemistry, we know that progress in that science can only occur either through incidental or chance discovery, or by mental activity in imagining, from what is known of chemistry, the possible existence of what is as yet no part of the science, and then putting this imagining or conception to the test of experiment. As to incidental or unpremeditated discovery, which is far more frequent as well as far more valued than predicted or anticipated discovery, it is not only necessarily the result of working in the laboratory, but it is also dependent upon the working knowledge, "practical" knowledge, scientific knowledge, of the discoverer, through which alone he is enabled to recognise the discovery for what it is. All advancement in the science of chemistry is therefore the result of and dependent upon the mental and physical practice of an art. There can be a treatise on the art of chemical discovery, just as there can be one on the art of wood-carving, and in either case, the success of the treatise, in making a man into a discoverer or into a wood-carver, will depend upon his previous possession of the requisite ability of mind and sense.

That progress in the knowledge of how to use the science of chemistry for industrial purposes is dependent upon the practice of an art, will be at once admitted —too readily admitted, in fact; for it should not be forgotten how largely the activity in that practice needs to be mental activity. In extending the science of chemistry by laboratory research, the chemist, for the most part, does his own manual work, whereas the chemist in the works still more frequently leaves all manual operations, in the carrying out of his ideas as to applying chemistry to a manufacturing process, to the artisans he has about him, men of experience and skill, but with very little scientific knowledge. There is no such difference as is implied by "scientific" and "practical" between the chemist in the research laboratory and the chemist in the works, except as to object and what that entails. The one is no more and no less a practical man than the other: the one works at the chemical art of extending the science of chemistry, the other at the chemical art of applying the science to effect useful ends; and in both cases the art depends upon the scientific knowledge of the worker. The object does indeed make a great difference in the art in the one case from that practised in the other. The need for inventiveness, for ingenuity, seems often to be much greater in the case of the works chemist than in that of the laboratory chemist. Hence, the satisfaction felt by many "practical" men in thinking of the works chemist as a chemical engineer, and hence also the assertion he makes that the object of the Society of Chemical Industry is essentially chemical engineering. But this greater call for ingenuity is surely more imaginary than real. What difference in kind is there, it may be asked, between the inventiveness, the ingenuity, the engineering skill of a Moissan in preparing fluorine or in distilling the most refractory metals, and that shown by a Solvay and a Mond in applying the knowledge, that common salt and sal volatile can change together into soda and sal ammoniac, to the successful manufacture of these products? And who will maintain that the chemist needs in one pursuit much more knowledge of physics and of the useful arts than he does in the other?

The undoubted difference, which does exist between the two pursuits, lies in this: the chemist engaged in technological pursuits must be economical, putting the consideration of profit and loss before all else, and must, therefore, work upon a large scale and consider the relative cost of materials, apparatus, power and its supply, skilled labour and attendance, handling and carrying of materials, disposal of noxious and other by-products, and several matters besides. The chemist occupied with the extension of the boundaries of science, in making scientific discoveries, need pay very little attention to economy of cost in relation to quantity, having other more pressing interests in view, and the knowledge that the outlay is made almost always once for all. There is only one economy that presses on him, as it does also upon the chemist in the factory; the economy of his own tim To gain this economy, he works on a very small scal because quantity of the product is of little moment, i perfect isolation and the scientific testing of its natu alone being important.

This difference between the two pursuits is inde great, and therein is to be found the reason for the comi into being of the Society of Chemical Industry. Bu before dealing with that, it is to be pointed out that t matter of profit and loss is one which falls fully within t definition already given of the object of the Socie of Chemical Industry. The question of profit and lo in an industry with an essentially chemical basis, fin its solution in the choice of the chemical processes, a in the choice of the plant best fitted to carry out the processes. That choice, at its best, will vary from tin to time with the advancing knowledge of the possib and actual applicability of chemistry to the indust concerned, and with the facilitation of the use of th knowledge.

Before the subject of the character of technologic pursuits is left, it may be of interest to say somethi about the significance of the terms, "chemical enginee and "chemical engineering." That of "engineering" one and the same in origin with "ingenuity," and impli fundamentally, the art or faculty of discovering or inven ing means to accomplish an end, not obviously attainab in known ways, engineering standing towards ingenui in much the same relation as science stands to knowledg That being so, to regard the term, "chemical enginee as signifying nothing more than one skilled in the co struction of chemical plant, is to take an altogether t limited view of it, and therefore an erroneous one. The may be sufficient objection to the use of this term, becau of its being often misunderstood, like the terms, "chemist and "engineer," themselves, but otherwise the titl "chemical engineer," would be much to be commende as being a full and comprehensive, logical and distinctr one, which cannot be said of the term, "applied chemist

After what has now been said in explanation and order to remove misunderstandings due to loose conce tions of the meanings of terms, it is hoped that t definition of the object of the Society which has be here offered as a desirable revision of that contained the by-laws, will be unanimously accepted and adopte in the wording of the new Charter of Incorporatio It reads thus: "The object of the Society of Chemic Industry is to promote in every way the use of the kno ledge of how the science of chemistry may be succes fully applied to manufactures and other industries It is surely a matter of supreme importance that the obje of a movement, which has resulted in the establishme of a great institution like the Society of Chemical Industr should be clearly laid down and apprehended.

Coming now to the history of the making of the Socie of Chemical Industry, we learn that, in 1879, Mr. Jol Hargreaves, of Widnes, was inspired with the thoug of starting in Widnes a chemical society on lines simil to those of the Tyne Chemical Society, which was a association of managers and chemists, not to be co founded with the Newcastle Chemical Society. T first recorded meeting to discuss this scheme took pla on November 21st, 1879, in Widnes. Other meetin followed, and the adhesion of such men as James Muspratt, Ferdinand Hurter, Douglas Herman, a George E. Davis was obtained. The scheme was quick enlarged to be that of a society for South Lancashi and a meeting was called in Liverpool, in January, 188 to consider rules and organisation, with Dr. Ludw Mond in the chair. The Committee appointed by th meeting met in Manchester, on the invitation of Pr H. E. Roscoe (Sir Henry, as he was to be), on April 19t 1880, and became a memorable one. Even before t actual meeting, the movement was set going by whi the formation of a Lancashire Chemical Society was be superseded by that of the Society of Chemical Industr This was done by Mr. Eustace Carey's proposing to S Henry Roscoe the formation of a Society of Chemic Engineers, and obtaining from him his approval of t project. After the already existing Committee h reported to the meeting what it had been doing a

had expressed its inability to make further progress with the scheme for establishing the Lancashire Chemical Society, and the Committee's report had been adopted by the meeting, Mr. Carey initiated the new order of things, at the suggestion, he said, of Mr. H. L. Pattinson, sen., of Newcastle-on-Tyne, by proposing, Dr. D. B. Hewitt, of Manchester, seconding, "that a committee be appointed to consider the question of the formation of a society for the promotion of the application of chemical science to manufactures." The proposal was unanimously adopted, after Dr. Mond had urged the desirability of making it clear by the name to be given to the Society that its basis was not local but co-extensive with the whole of the United Kingdom, and that its object related strictly to applied chemistry. It was also suggested by Dr. Angus Smith that its object should be concerned with the whole field of manufacturing chemistry, and by Mr. J. F. Allen, of Manchester, that it should also take in calico printing, metallurgy, and other industries in which chemistry played a part. Here, then, we see the scope of the new Society fully drafted, for we may take it for certain that in extending its reference beyond the limits of Lancashire and its industries to those of the whole of the United Kingdom, the intention of Dr. Mond and the others was to prevent the future Society being restricted to any one locality or limited to some only of the industries to which the science of chemistry is applicable. Mr. Hargreaves, who had worked so well in setting the stone rolling within this county of Lancaster, handed over at this meeting his secretarial office to Mr. G. E. Davis, then of Manchester, who for two sessions was to act with such advantage to the young Society as the Society's honorary General Secretary.

During the year intervening between this meeting and the meeting in London which inaugurated the Society, Sir Henry Roscoe brought his wisdom and power as an organiser and his knowledge of matters and men to bear upon making the birth of the Society the brilliant event which it turned out to be. It would be ungrateful to overlook the services of the Committee, composed of Messrs. J. Fenwick Allen, J. Brock, J. Campbell Brown, J. H. Crossley, Alfred E. Fletcher, J. C. Gamble, H. Gaskell, jun., Jno. Hargreaves, W. D. Herman, D. B. Hewitt, F. Hurter, L. Mond, J. L. Muspratt, Edward Schunck, Angus Smith, Frank Spence, Peter Spence, and T. E. Thorpe (three of whom and the son of a fourth were to become Presidents of the Society). The Society must for ever feel gratitude to that Committee, but the fact is on record that they, at a very early date and repeatedly afterwards, placed matters largely in the hands of their chairman, Sir Henry Roscoe, and thus imposed upon him, and upon Mr. George E. Davis, a considerable amount of work and responsibility. The minutes of the meetings of the Committee held between that date (April 19th, 1880) and that of the inauguration of the Society (April 4th, 1881) testify to the thoroughness with which Sir Henry Roscoe discharged the obligations he had accepted. No one, again, was more regular in attendance at these numerous meetings than Mr. Carey, whose definition of the object of the proposed Society, as adopted at the Manchester meeting, soon again came under consideration, namely, at the meeting in Liverpool, a week after the Manchester meeting, when it was considered along with several other suggested definitions, from among which it was selected and again unanimously approved and adopted. Later on, the attempt was made to express within the title to be given to the Society the purpose of its formation, but the words, "advancement of chemical industry," thus used, are wanting in the clearness and exactness of the words of Mr. Carey's original motion, namely, "promotion of the application of chemical science to manufactures," which can only be improved upon by substituting "industries" for "manufactures," and making one or two additions.

The Society was inaugurated in London on April 4th, 1881, at the rooms of the Chemical Society, Burlington House; a full report of the proceedings is given in an appendix. Sir Henry Roscoe was elected President; the late Sir Frederick Abel, the late Sir Lowthian Bell, Mr. F. H. Gossage, the late Dr. G. D. Longstaff, Mr. E. K. Muspratt, the late Mr. Hugh Lee Pattinson, Dr. W. H. Perkin, the late Sir Wm. Siemens, the late Dr. Angus Smith, the late Mr. Walter Weldon, the late Prof. A. W. Williamson, and the late Dr. James Young, Vice-Presidents; and a "Committee," consisting of Sir Wm. Abney, Mr. Alexander Chance, Sir Wm. Crookes, Prof. Chas. Graham, the late Mr. Peter Griess, Dr. D. B. Hewitt, Mr. David Howard, the late Mr. James Mactear, Mr. John Spiller, the late Prof. Sprengel, the late Mr. Henry Tate, jun., and Mr. Philip Worsley. The late Mr. E. Rider Cook was hon. treasurer; Mr. Thos. Tyrer was hon. Metropolitan secretary; Mr. Eustace Carey, hon. Northern secretary; Dr. Ludwig Mond, hon. Foreign secretary; and Mr. George E. Davis, hon. general secretary.

The present occasion does not give time for recounting the services rendered to the Society by many of the bearers of these names, and the important influence which they have exerted over the progress of chemistry and of its applications to the arts.

The Society has made a most gratifying progress in the number of its members. Beginning with 297 when founded, it is now about four and a half thousand. At the date of the first Annual Meeting, the number had risen to 1140. In the early life of the Society after that date, the annual increase was more than 200; in 1884 it was even 400, but this rate slowly subsided to such an extent that the total increase for the five years, 1893-7, was only 245. The number then rose again more rapidly with each year, though not uniformly, but since that year the average annual increase has been 146—a remarkable number, it will be admitted, particularly when consideration is given to the fact of the large annual loss by death and defection in so numerous a body which has to be made good before any increase can be shown. The greater rate of growth within the last decade or so expresses the accession of strength consequent upon the opening of Sections of the Society in the United States and, though as yet to a much less degree, in Canada and Australia. It must not be overlooked, however, that the Society had already a considerable number of members in America before the New York Section was formed.

Another interesting comparison of the rate of growth in the numbers of the Society may be made. In 1886 there were 2270 members; in 1900, fourteen years later, there were half as many again, namely, 3460; now, there are nearly double as many as in 1886, namely, 4450, through the addition of nearly 1000 within the last six years. Apart from the great expansion in America and elsewhere abroad, the Society has hardly grown in numbers in the British Isles since, say, 1886. In these islands the membership was distinctly higher in the year 1900 than it is now. Only the London Section and the Yorkshire Section show a noticeable enlargement since 1886, and no falling off from the numbers of the year, 1900. It would be well if we could know exactly why this is, and were able to assure ourselves that, collectively and individually, we none of us are to blame for this stagnation in local growth. A table, showing both the change in the number of the members in every year and in different localities, prepared with the kind assistance of the General Secretary, is appended to this Address.

Throughout its life the Society has been dependent wholly upon the modest subscriptions of its members and the sale of its Journal. In thus receiving the total neglect of benefactors, it has been unlike most of the institutions which are subserving great general interests, even the Chemical Society having received donations and legacies which, apart from its endowment for research purposes, amount to some £4750, with no yearly item of rent to meet out of its income. Notwithstanding the fact of having been left to its own resources, the Society, under the healthy administration of its affairs which it has experienced, neither parsimonious nor too liberal, can show to-day invested funds little inferior in amount to those of the Chemical Society when research and other endowments are not included. It must, however, not be forgotten that, but for the interest on its investments in the past, the Society would have had a balance sheet for 1905 showing expenditure a little in excess of income, not including in this, of course, life com-

position and entrance fees. In 1884, before the Society had funds to invest, this event actually did occur. At present, there are 121 members of the Society who have paid the composition fee, which until 1894 was £15, and since then has been £20.

One characteristic of the Society is that by its constitution it is divided into local Sections. Another hardly less significant character is the diversity of the several pursuits in which its members are interested. Let us consider this character first. It is a tradition, that among the earlier notions of what such a Society as ours should accomplish was that it was to serve to bring together men engaged in the conduct of the applications of chemical science with those who devote their powers to developing the science itself. Desirable, however, as that service undoubtedly is, and effective as it may prove to be in benefiting these two orders of members, it is surely one quite subordinate to that of drawing men together who are occupied with *different applications* of chemistry. Inventiveness is the foremost qualification for success in any progressive industry. Keenness of observation, receptivity for novel ideas, imaginative power, the possession of all these being assumed—for that assumption is indispensable—where shall a man so qualified best turn when he would develop by his inventiveness an industry in which he has interest and training? Indisputably, he must turn to the experience reported in the conversation and writings of others engaged upon problems like his in principle, but unlike them in the field of the operations to which they relate. It is true that the association of men concerned with the same or almost the same industry must be conducive to much good, and have great attractions, and the Society serves excellently for the purpose of thus associating those having the same or closely kindred pursuits and interests. It is evident also that the existence of several specific societies indicates what a great desire there is for opportunities for closer intercourse and fuller consideration of particular interests than a society more comprehensive is supposed to be in a position to afford. But to whatever extent the Society of Chemical Industry may be thought to serve this end sufficiently or to fall short of doing so when compared with the working of a specific association, this purpose, like that just referred to, is of quite minor importance when compared with the possibilities for effecting great things which membership of the Society offers by affording opportunities for interchange of knowledge and ideas between chemical engineers more or less widely separated in the nature of the chemical industries which they are severally advancing. The subject cannot receive further notice on the present occasion, but recognition of this aspect of the unique character of the Society, as promising more than anything else to favour invention and in that way to advance chemical engineering, calls for the utmost attention, when considering the value of the Society to its members and to the cause of chemical technology. It will be seen that, from this point of view, the highest value of membership of the Society is only obtainable by those members who seek to find something of interest in all parts of the work of the Society. He who confines himself to the discussion which his own subject receives in the proceedings of the Society is throwing away the best part of the advantages which membership offers him.

The advantage to the whole Society and to each of its members of having as much as possible of its business conducted at different centres by dividing off the Society into Sections is sufficiently obvious to call for little comment. Meeting together with a frequency impossible for those widely separated by distance, the members of a Section have the opportunity of chancing upon suggestions for invention in their own industry to which procedure in other industries now and again gives rise. Rarely as it must happen that any fruitful suggestion is thus obtained, the chance of it may be of unexpected value. Another and much more obvious advantage is the extension given by the meetings of Sections to the opportunity for the discussion of papers. These discussions at meetings may be not only of value in bringing out more clearly the points of a communication made to the meeting, but help to make the meeting more attractive and serve to show sympathy with the author of the communication in the trouble he has taken to make it. Those, however, who take part in the discussion can seldom be other than those specially informed on the subject, and yet it is the suggestiveness of the paper and its discussion to the members present who are *not* engaged in that branch of chemical industry which promises to be of more consequence than anything it can be to those who are themselves engaged in that branch.

Thirteen Sections of the Society have been formed, the names of which, taken in the order of the dates of their formation, are London, Liverpool, Manchester, Newcastle, Birmingham, Scottish, Nottingham, Bristol, Yorkshire, New York, Canadian, Sydney (N.S.W.), and New England. The limits of this Address preclude the attempt to give some account of each of these Sections. They have shown widely differing degrees of vitality. This Section of Manchester has all along been a very vigorous one. Its first meeting occurred on February 6th, 1883. London, from the density of the distribution of members within the Section, and because of its many chemical industries, could not fail to prove to be the largest of the Sections in the United Kingdom, but its output of papers is not quite so great as it seems, because of the fact of its receiving more papers from beyond its limits than do any of the other Sections. Through no fault of its own or of the Society, this Section is not infrequently taken to be the Society itself, owing to the fact that the headquarters of the Society are also in London, and that the constitution of the Society is imperfectly apprehended by the public, but also due to the prominence it acquires through its great activity.

The value of being members of the Society of Chemical Industry, within a local Section, over that of being members of an independent, self-contained local society, is that a Section of the larger Society has assurance of a longer and much fuller life, in that it is not wholly dependent upon its own efforts, as is a local society, and is not confined within the limits of its own powers. It finds, in the Society of which it is a part, the means of making known to a very much larger body than itself, what it is doing, and in return receives and is influenced largely by what is being done in the other Sections of the Society. "Local centre" is not a good and logical expression, but it is nevertheless one which is peculiarly well-fitted to indicate at once what a local Section of the Society is, as compared with a self-contained local society, since each Section becomes, in a very real sense, the centre for itself of the whole Society, shining its light upon all parts of it, and in return being itself illumined by them. It is indeed hard to imagine the case of a local Section which would not find far more loss than advantage in cutting itself adrift, in order to form itself into an independent association, even though, as is the fact, oceans may separate it from some of the other Sections. Too important to be passed over without comment, notwithstanding the need for brevity, is the spread of the Society into the United States of America to such an extent as to have led to the formation of two Sections there, which include 1350 members. A corresponding growth, rapidly increasing, in Canada and Australia has led to the formation of a Section in each of those countries. Not to dwell upon the evidence of international amity which the existence of these Sections affords, the evidence it also affords of the estimation in which the Society is held abroad is such as ought to induce many in this country to recognise the probable advantage to themselves of joining the Society.

The government of the Society is at present regulated by by-laws, which can be amended, after due notice has been given, at any general meeting of the Society, but it is hoped that the Society may soon have a Royal Charter to work under, and to secure for its recommendations even greater consideration in legislation and other public matters than they have already received.

Only two of the offices of trust and responsibility in the Society can ordinarily be filled for any long period by the same persons, namely, those of the Hon. Treasurer and Hon. Foreign Secretary, although there are means provided by which the services of those who have filled them may be recovered, should a year's interval have shown that the

recall of such persons to office is to be desired in the interests of the Society. In this connection, one of the noteworthy points in the constitution of the Council is that the fact of having been President of the Society confers no qualification to have a permanent place on the Council. Why should it? Since the Council is appointed to administer the affairs of the Society to the best advantage, every member of it should have been elected on the sole ground of the superior fitness for office which he is believed to possess.

Another noticeable point in the constitution of the Council is that the Chairmen and the Honorary Secretaries of all the Sections are, *ex-officio*, members of the Council, and that, as far as practicable, special facilities are afforded for securing their presence at its meetings, and for getting their opinions and advice, when they are obliged to be absent.

The work done by the Council and by its various Committees is and always has been very considerable. Some evidence of this may be obtained by reference to its annual Reports as they have appeared in the Journal of the Society.

Meetings of the whole Society, as distinguished from the many which are held by its various Sections, that is, the Society's General Meetings, are, almost of necessity, rare events, there being usually in one year only the Annual Meeting itself; this year there happens to have been another to consider the application for a Royal Charter. The General Meeting held in London in June, 1881, was not only remarkable as being the first one, but also for the importance of the papers read before it. The next General Meeting was not only the First Annual Meeting, and occupied with important papers, but it has just now the interest attaching to it of having been the first General Meeting held in Manchester. The nineteenth Annual Meeting is memorable for having been the first to be held under an American President, Professor Chandler; the twenty-third for having been held in New York; and the twenty-fourth for having had as its President another American member, Dr. Nichols, of New York. It may be of interest to mention that the reading of papers was excluded from the business of the second Annual Meeting and, with the exception of the fourth Annual Meeting, papers have not since been read at General Meetings. This seems to be the only suitable plan, so long as the Society has its Sectional Meetings for the reading of papers.

The Society started with four Honorary Secretaries, of whom, one of the founders, Dr. Mond, the Foreign Secretary, still fills that office, to the great benefit of the Society. At the second Annual Meeting (1883) Mr. George E. Davis, another of the founders, who, as General Secretary, had been of the greatest service in putting the Society into shape and working order, retired from that office, and was made a Vice-President. At about the same time, the honorary offices of Northern and Metropolitan Secretaries, having become superfluous by the formation of Sections in London, Liverpool, and Manchester, were abolished. A salaried General Secretary was appointed, in the person of Mr. C. G. Cresswell, who still serves the Society with the same zeal which he displayed from the beginning, and now, also, with the skill and judgment which he has acquired during his twenty-four years of office. Mr. Eustace Carey, another founder, the Northern Secretary, was put on the Council, and has always, to the present day, when he is being elected to the office of President, taken great interest in the progress of the Society. Mr. Thomas Tyrer, the Metropolitan Secretary, became Honorary Secretary of the London Section, and has, through the whole life of the Society, served it in the most efficient and self-sacrificing way, and in almost every office, including the highest, for he was President in 1895-96.

Far and away the most important visible work of the Society through its Council, and under the latter through the Editor, Sub-Editor, Abstractors, and Publication Committee of the Council itself, has been the production of the Journal of the Society, which will soon have completed its twenty-fifth annual volume. All who know the Journal seem to agree in recognising its great value and merit. Some go so far as to hold that the Society of Chemical Industry is little else than the producer and publisher of its Journal. If that were so, its existence would be more than justified, and the subscription of each member be more than repaid him in supplying him with the Journal. To what extent it approaches being little else than that, is matter for serious consideration. It has been the chief object of this Address to bring out, to those who may not have recognised it, what great possibilities the Society should possess in helping on invention in the minds of its members. That is something quite above the work of issuing a Journal, even so excellent a one as ours. If, in a sense, it is allowable to look upon that Journal as everything to the members of the Society, that can only be because in so big a Society it affords the only universally available way of letting every member know what is going on in all branches of chemical industries, and not merely in one branch, in the hope that the object of the Society may in this way best be served. But whatever view may be taken of the function of the Journal, its very great value in many ways is evident to everyone familiar with it. From the first, it has been edited by Mr. Watson Smith, acting in accordance with the advice of the Publication Committee, and we cannot wonder at the pride he takes in his fame as Editor of so great a work. For many years Mr. Cresswell has performed an important part of the very great labour of editing, and taken very much interest in successful endeavours to improve the Journal. How well Mr. Burton has done his part in assisting the Editor and Sub-Editor may be learned from the fact of his having been asked to undertake the indexing of the volumes in succession to Mr. Renaut, who, for so long, and until failing health obliged him to lessen his work, has prepared both the Annual and the Collective Indexes. Concerning the arduous services voluntarily given by the Publication Committee, nothing in the way of praise would be excessive. The Society has no benefactions, it is true, but the work of the Publication Committee must be counted as a continuous gift of the greatest value.

There is one serious matter in connection with the publication of the Journal, and that is its cost, even after everything has been done to reduce it without affecting the value of the Journal. In particular, there has to be considered the increasing cost of the collective indexes. They are offered to members at prices far below what they cost, and even at that rate have but a limited sale. Were the Society a business firm, it would naturally withdraw from the further production of collective indexes. But it feels it to be its duty to strive to supply these indexes to its members, for it is difficult to understand how any member who is in earnest in prosecuting work in any part of chemical industry should not want such an index, and should fail to recognise what assistance he might derive from having it at hand and frequently consulting it. It would be a valuable benefaction to the Society and to the cause of progress in chemical industry if some one were to endow the Society with a fund to defray part of the expense of producing the collective indexes, already making too great a demand upon the Society's income.

One other matter about the Society's Journal, of too great importance to be passed over in silence, is the change made a few years ago from a monthly issue to a half-monthly one. This change has made the cost of production of the Journal greater than it was. It is disheartening to know that the change is by no means so much valued as it should be. Everywhere around us we see steps being taken to quicken the rate of transmitting news and information. In sympathy with this, it is the effort of the Council to have all the steps in the progress of applying chemistry to the arts made known as quickly as possible to its members, one means adopted being a fortnightly issue of the Journal. It ought to be, and must be, that every earnest member should welcome the change. The Journal is, however, interesting in a way to many members who are satisfied to take matters easily, and it is some of these who almost resent having to turn over the pages of a new number more than once a month. But, as in the case of the collective indexes, it is the duty of the Council to facilitate reference to the past volumes of the

Journal, so is it its duty to keep its members informed of what is going on with as little loss of time as possible. With the expression of the wish that the importance of keeping our knowledge well up to date, than which, perhaps, no other wish would have in its fulfilment greater effect upon the advance of chemical industry, this Address is brought to an end.

APPENDIX A.

[*Reprinted from the "Chemist and Druggist," April* 15, 1881.]

THE SOCIETY OF CHEMICAL INDUSTRY.

On Monday, April 4, 1881, a meeting was held in the rooms of the Chemical Society, Burlington House, which was notified as the inaugural meeting of a proposed society with the above as the suggested title. About 60 gentlemen were present, including many of the best known chemists of the day. The following statement, which had been previously circulated, will sufficiently explain the proceedings antecedent to this meeting.

At the last general meeting of the Sub-Committee, held at the Owens College, Manchester, on December 14, 1880, it was resolved that a Society of Chemical Engineers be established, and a Sub-Committee was appointed to make preparations for this meeting, and for considering the details of the scheme to be laid before you.

It is not necessary to go into all the particulars which have led up to this meeting; suffice it to say that for some time the want of a Society has been felt, the object of which is the advancement of manufacturing chemistry in the United Kingdom.

In order to accomplish this it is desirable to establish a Society which may be the means of bringing together, at stated intervals, all those who possess chemical, physical, and engineering knowledge, and who use this knowledge in the utilisation of chemical action on a manufacturing scale, and who have the charge of, or an interest in, chemical industries. It may, indeed, prove afterwards desirable to found a distinct branch of the engineering profession, to be composed of persons who possess the aforesaid knowledge, and who may be designated as chemical engineers.

It is unnecessary to state the advantages which would doubtless accrue to the various branches of chemical industry by the training in all chemical, physical, and engineering matters connected with the business, of all those who have charge of processes; but independently of this, such a Society as is proposed to be established would have certain objects in view, which may be briefly stated as follows:—

To enable persons interested in chemical industries to meet, to correspond, and to interchange ideas respecting improvements in the various processes.

To publish information relating to the aforesaid, by means of a journal or otherwise.

To acquire and dispose of property for such purposes, and to do all other things incidental or conducive to the above-named objects, or any of them.

It is proposed that the Society shall consist of members, associates, students, and honorary members.

Members may consist of persons who by their attainments may be considered by the Council to be eligible.

Associates may consist of persons practically engaged in such matters, and considered by the Council and Local Committees to be eligible.

Students may be those who are disqualified by age or otherwise from election as members or associates.

Honorary members must be selected by reason of their distinction in matters relating to chemical industry.

It is proposed that all who subscribe their names to the memorandum shall be admitted as the first members of the Society, and afterwards that all persons be elected in accordance with the bye-laws which your first Council will be instructed to prepare.

There are two features in the scheme which demand attention; the first is to hold meetings at which papers relating to questions of chemical industry may be read and discussed, and the other is to publish a journal whenever the Council deem it advisable and the funds enable it to be done.

It is proposed to hold annual general meetings at such times and places as may be decided upon at each annual meeting, and further, it is proposed to organise district or local sections, branches of the parent Society, at which members and associates may meet oftener and more conveniently than would be possible if only annual meetings were held.

The foregoing statement having been read by Mr. George E. Davis, of Manchester, the honorary secretary *pro tem.*,

Professor Roscoe, who presided, explained briefly the objects of the proposed Society. Having spoken of the work accomplished by other societies, the Chemical, the Institute of Chemistry, and the Society of Public Analysts, he said the new Society would not, in his opinion, interfere with the work of any of these. The idea of those gentlemen who had already worked in connection with it was to found a Society which should stand in relation to chemical industries in much the same position as the Iron and Steel Institute stood in relation to the great iron industries of this country. That Institute had proved most valuable and useful, and he believed this suggested Society would bring results of similar value. After commenting on some of the passages in the statement already quoted, and suggesting that perhaps it might be found desirable to hold two general meetings in the course of each year, one in London and the other in some provincial centre, besides establishing local branches, he proposed—

> That a society for the advancement of chemical industry be and hereby is established.

Mr. W. H. Perkin seconded the motion, which was put to the meeting and declared by the Chairman to be carried unanimously.

The Chairman then called for the next resolution to be proposed, when

Mr. Kingzett rose and said he should like to be allowed to make a few remarks before they proceeded further. As a member of Council of the Institute of Chemistry, and out of loyalty to that institution, he would like it to be considered whether this new Society was really necessary. One of the objects of the Institute was to promote the interests of manufacturing chemistry and of all branches of the science allied thereto. It had, therefore, seemed to many and to himself that there was no reason why the Institute, if properly developed, should not achieve the end proposed to be attained by this Society, and that the latter would but afford a means of drawing another two guineas a year from the pockets of manufacturing chemists. He only offered these remarks for the consideration of members of the Institute.

The Chairman remarked that the resolution to form the new Society had been already carried.

Dr. Longstaff thought they had been taken somewhat by surprise. For his part he could not conceive what this new Society was going to do which the other societies did not, or could not, accomplish. Was it supposed that manufacturers who had studied hard and spent large sums in learning how to improve their processes were going to communicate the result of all their researches at meetings of this Society? If not, what other object was proposed that the other societies could not accomplish? He was an old member of the Chemical Society, and was also a Fellow of the Institute of Chemistry, and should be happy to meet in any other society, but he thought they ought to be told what were the special objects of this proposed association.

Mr. Lowthian Bell said no doubt the Chairman was right in saying that the resolution had been carried by a show of hands, but now that they had before them these *quasi* amendments it might be desirable to point out the anticipated advantages of such a Society. He could corroborate fully what the Chairman had said as to the advantages and utility of the Iron and Steel Institute. He did not know that gentlemen joining that had done so altogether from philanthropic motives, but there were

other good objects which might fall somewhat short of this. They might meet together to discuss subjects of common interest without considerations of abstract benevolence. Perhaps, as one of the parents of the Iron and Steel Institute, he might be supposed to look upon it with especial indulgence, but he had experienced much benefit and pleasure from attending its meetings, and still did so, though not now very actively engaged in manufacture. He considered that the Institute had given to the manufacturing iron interests a degree of dignity which they would not have otherwise attained, and he believed that a similar association would confer equal benefits on the great trades of chemical manufactures. He had no doubt that his old friend, Dr. Longstaff, who was always noted for his candour, would soon come to appreciate the value of such a Society, and would do his best to promote its interests.

A MEMBER pointed out as one object of the new Society, that though among manufacturing chemists there were many fully competent to take a high place among scientific chemists, there were also many engaged in some particular branches of the manufacture who were perhaps too modest to associate themselves with either of the other societies, but who could both give and derive great advantage from practical discussion.

The SECRETARY OF THE CHEMICAL SOCIETY OF NEWCASTLE spoke of the kind of practical discussions which were carried on there, and said that they were of great service to the manufacturers and managers of works who took part in them.

Professor ABEL (President of the Institute of Chemistry) said an objection had been raised to this proposed Society on the ground that it might interfere with the functions of the Institute of Chemistry, and on the other hand it had been suggested that the Institute could fulfil the work which was now desired to be accomplished. Having a little acquaintance with the working of the Institute, he had concluded that the objects proposed by this Society were entirely distinct. He could also add his testimony to the great services which had been rendered by the Iron and Steel Institute, and he saw no reason why an institute of chemical industry should not attain an equally important position. There were subjects of vast importance which persons actually employed in processes would be very happy to discuss together. There had been found no reluctance in the Iron and Steel Institute to discuss subjects in detail, and he did not think such a difficulty was likely to occur.

Dr. HEWITT said that the object of starting this Society was the fact that while good analysts and good manufacturing chemists were to be had abundantly, there was not a sufficient supply of men of engineering skill also versed in the arts of manufacturing chemistry. They could obtain plenty of men capable of carrying through processes in a laboratory, but not competent to apply these on a large scale. There were many processes now awaiting development. His experience was that the difficulties manufacturing chemists had to overcome were rather mechanical than scientific.

Mr. KINGZETT wished it to be understood that his only object in raising the question was to ascertain the views of Fellows of the Institute. The expressions of the President of the Institute quite disposed of any possible objection.

Mr. LOWTHIAN BELL proposed the next resolution: That those who entered their names at this meeting should be the first members of the Society, and should be admitted without entrance fee, and that the same rule should apply to others who joined within the next six months after being approved by the Council. In reference to some remarks that had been made, he hoped that the modesty of those who did not claim to be scientific men would not prevent them from joining the Society. It was practical workers that they wanted. He was glad to see that his friend, Dr. Longstaff, had given in his name, and he hoped that some others who had perhaps come to scoff would remain to help on the Society.

Mr. GOSSAGE seconded this resolution, which was supported by a few words from Dr. Longstaff, and carried unanimously.

The CHAIRMAN said that the next business was to agree upon a name for the Society.

Mr. CAREY proposed that it be called the "Society of Chemical Engineers." His experience, he said, showed that chemistry had far outrun construction, and that the main requirement of manufacturing chemists at the present time was more skill in the construction of apparatus He thought the title suggested would indicate with definiteness that the chief purpose of the Society was to encourage development and engineering ability as applied to chemical action.

This proposal having been seconded, Mr. WELDON moved as an amendment: That the title "Society of Chemical Industry" be adopted. He thought that the suggested title of "Society of Chemical Engineers" would unwisely restrict the objects and membership of the Society, and that if adopted there would be still an opening for one more society. The term "Chemical Industry" included all that could be included by "Chemical Engineering" and something more. Referring to the objections which it had been said existed on the part of manufacturers to give information concerning their processes, Mr. Weldon said that he had often conducted representatives of foreign works over chemical works here, and his experience was that information was always very willingly given. He was confident that, so far as alkali manufacturers were concerned they would very willingly and gladly embrace opportunities to meet together and discuss subjects of common interest.

Professor ARMSTRONG believed that if they entitled the Society a "Society of Chemical Engineers" it would have a very deterrent effect on professional chemists joining. He considered that there existed a great want of a means for bringing together scientific and manufacturing chemists, and a "Society of Chemical Industry" would meet that want. There were many processes awaiting development, and the Society, by offering opportunities for the discussion of these by practical men, would be of great service.

Mr. TYRER said there was an advantage of definiteness about the title proposed by the resolution, while that proposed in the amendment was more comprehensive. Could they not have a composite title which should cover all, and at the same time express the special objects desired, as, for instance, the term "Society of Chemical Industry and Chemical Engineering"?

Dr. MOND said the title "Chemical Industry" undoubtedly included Chemical Engineering, and the latter subject would necessarily be prominent in the work of the Society. At present the term "chemical engineer" was only used by a very small number of persons, and he had found that, as a rule, these knew very little of chemistry. There was great need to educate a class of men who should be engineers and should understand chemistry.

Mr. MUSPRATT said that chemical science was often at fault, as well as engineering skill. There was, for example, still wanted in alkali manufacture a satisfactory process for the recovery of sulphur from the waste. They must take care, in selecting their title, not to frighten off chemists. The term "Chemical Industry" included all.

Mr. FORSTER preferred the term "Chemical Engineers." His experience was to the effect that without engineering skill chemical manufactures could not be carried on with profit, and he was convinced that it was this department of knowledge which it was especially necessary to develop.

Mr. LOWTHIAN BELL would like to ask how the adoption of the term "Chemical Industry" could prevent any chemical engineer from joining the Society? On the other hand, he could easily understand the converse case.

Mr. DAVID HOWARD advocated the adoption of the title "Society of Chemical Engineers" on the ground that he did not know what was meant by "Chemical

Industry." He understood what was an industrious chemist, but the term "Chemical Industry" was so vague as to include too much. The way to fail was to try to include everything. Those who advocated the term "Chemical Engineers" had definite objects, and knew what they wanted to accomplish, and for that reason and on account of the rather uncommon character of the title, he thought the Society more likely to be successful than if entitled vaguely the "Society of Chemical Industry."

Mr. SPILLER pointed out that the title used by members of the Institution of Civil Engineers was M.Inst.C.E., and there might result confusion from Chemical Engineers having the same initials.

Mr. CAREY said that difficulty could be obviated by using the letters Chem. instead of the C. merely. He considered the term "Society of Chemical Engineers" was more likely to attain honoured recognition than "Society of Chemical Industry."

On a show of hands being taken the Chairman declared the amendment carried in favour of the term "Society of Chemical Industry."

The election of office-bearers was then proceeded with and scrutators were appointed to examine the voting-papers, who subsequently reported the result as follows:—

PRESIDENT.
Prof. H. E. Roscoe, F.R.S.

VICE-PRESIDENTS.

Prof. F. A. Abel, F.R.S.	Jas. Young, F.R.S.
Prof. A.W.Williamson,F.R.S.	F. H. Gossage.
I. Lowthian Bell, F.R.S.	E. K. Muspratt.
W. H. Perkin, F.R.S.	H. Lee Pattinson.
Dr. C. W. Siemens, F.R.S.	Walter Weldon.
Dr. Angus Smith, F.R.S.	Dr. G. D. Longstaff.

COMMITTEE.

Capt.W. de W.Abney, F.R.S.	Jas. Mactear.
Prof. Chas. Graham.	H. Sprengel.
W. Crookes, F.R.S.	Henry Tate.
Peter Griess, F.R.S.	Philip Worsley.
Dr. D. B. Hewitt.	J. Spiller.
David Howard.	Alex. Chance.

TREASURER.
E. Rider Cook.

SECRETARIES.

Eustace Carey.	Ludwig Mond.
Thomas Tyrer.	George E. Davis.

In reply to a question as to where would be the head-quarters of the Society, the CHAIRMAN said he supposed that would be settled by Council, but, as the inaugural meeting had been held in London, he should presume that subsequent meetings were also likely to be held there.

A discussion next took place as to the amount of subscription, and both one guinea and two guineas were suggested. It was ultimately decided to fix the first subscription at one guinea, understanding that this arrangement was tentative, and leaving the Council to fix the amount when the requirements of the Society were known.

In regard to meetings, Mr. GEORGE E. DAVIS explained that the idea of the sub-committee who had proceeded in the matter hitherto was that local sections would be formed and would hold meetings in their several localities, and that a general meeting of all sections would be held annually.

It was then agreed to hold a general meeting to receive the report of the Council when the bye-laws and general arrangements had been agreed upon.

Mr. TYRER suggested that the sense of the meeting should be taken, as a recommendation to the Council, as to whether such a meeting should be held in London or in the country. On a show of hands being taken a general preference for London as the place of meeting was indicated.

Votes of thanks to the Chemical Society for the use of their rooms, and to Professor Roscoe for presiding, were passed and acknowledged, and the meeting terminated.

APPENDIX B.

Comparison of Membership in 1886, 1900, *and* 1906.

* Included under United States in 1886 and 1900.
† Included with Nottingham in 1900.

The PRESIDENT supplemented the printed matter on page 666, by stating that a chemist had said to him, that he had benefited very considerably by seeing processes carried on in works very different from his own. They could not go to learn into works of the kind they themselves were engaged in. To do that would be monstrous and unfair, but they were able to go and see operations carried out at other works, and it was quite open for them to make use of what they had there seen in the industries they were engaged in themselves.

Sir HENRY ROSCOE proposed a vote of thanks to the President for his Address. He had given an Address about their Society, which from its formation up to its manhood, had become one of the most important scientific societies in the world. He had spoken well and clearly with respect to the objects of the Society.

Sir Henry proceeded to read extracts from the printed Address, to show the value of the opportunities which the Society afforded its members for the interchange of ideas. That, he said, seemed to him a very wise definition of the work of the Society. They, who met in that room in Owens' College five and twenty years ago, might, he thought, be proud of their bantling. He thought the progress of the Society had been unequalled by that of any other society with which he was acquainted. Not only had it received recognition from men of science, for if they looked through the names of their Presidents and Vice-Presidents during the last five and twenty years, they would find that some of the most eminent chemists and scientists had adorned their presidential chair, and had rendered important services in the domain of applied science. He would not mention their names, for they were household words, but he thought that would serve to show that their Society, in the short period of its life, had placed itself on the same plane as the older societies in the country. But they were not only a British Society, they had spread their wings and gone over the field, not only to British Colonies, but to their cousins in the United States; they had ceased to be national and had become international. As one of the founders of the Society, he would like to congratulate them on the great results from the efforts of the President and the members of the Council. He had been struck when he attended the meetings to see the immense interest taken by the members of the Council in the work of the Society. With regard to the desirability of obtaining a Charter, and to the application which had been made for a Charter, he felt that that was a very

important point, and that the obtaining of a Charter would assist them much, and that the efforts made by the Council would meet with success, and that before long, probably before the next meeting of the Society, they would be able to congratulate themselves on having a Charter and on placing the Society in a truly satisfactory position. They were all glad to come to Manchester again; Manchester had always received them well. He had great pleasure in moving that the best thanks of the meeting be accorded to the President for his Address.

Mr. EUSTACE CAREY seconded. He quite indorsed everything which Sir Henry Roscoe had said about the usefulness and the character of the Address. There were two points to which he would like to draw attention; one was, that the President had thought well to record the name of Hugh Lee Pattinson, of Newcastle. It was in 1876 that he made the suggestion, and that suggestion slumbered in their minds until they brought it out on the lines which he intended. There was another point to which the President had alluded: the usefulness of seeing and learning about processes other than their own. That certainly was so, and in their Sectional work it had occurred to him that enough use was not made of the advantages to which the President had alluded. They did not make enough use of them because they were afraid of exposing their ignorance. They were too reticent. A little obscurantism was growing upon them. He remembered speaking about that to Dr. Markel: that they were getting a little too careful about showing to others what they themselves were doing. It arose from the feeling that they were at the top of the tree and that the other fellow might get there himself. Dr. Markel had said: "Well, if the other fellow considers he is at the top of the tree, I am quite certain he won't stop there long."

The vote was passed very cordially.

The PRESIDENT expressed his thanks to the members for the vote which they had just passed to him, and then announced that the next business was the presentation of the Society's medal.

THE MEDAL.

The PRESIDENT said that the Society gave its medal in order to show its high appreciation of, its satisfaction in, and its gratitude for—in a word, to signalise its great pleasure in, the success of the recipient of the medal in advancing chemical industry in one or another of its branches. The Society's aim was to advance or develop the knowledge of the applicability of chemical science to arts and manufactures, and it knew no better way of furthering its object than by pointing out for the benefit of the would-be technologist, someone eminent for the work that he had accomplished in the field of chemical technology. In Dr. Ludwig Mond they met with the man who had been eminently successful in that way. The history of his important inventions, improvements, and discoveries came to them almost like a realised, marvellous dream. Having, in connection with the great British Leblanc soda industry, invented a method by which the sulphur which was used in the manufacture could be profitably recovered, he turned his attention to the Belgian Solvay process, and commenced that wonderful series of discoveries they now owed to his genius. This process had been really discovered, or invented, in this country, but had not been successfully worked, and much later on, it was virtually re-invented by Solvay and made a process which could be carried on in successful competition with the older method of making soda. But in this country, the ammonia soda process became a great success—a brilliant success—by the beautifully simple arrangement adopted by Brunner and Mond, of placing works in Northwich over the salt beds, letting down water into the salt, and pumping it up again as brine into the apparatus. By the addition of various improvements which Mond made in the working, it had become a thoroughly established and signally successful process. In that process, the ammonia soda process, ammonia was the most important agent required. Mond, therefore, turned his attention to the economic production of ammonia, and he ascertained that when coal was burned in an atmosphere of steam, it yielded up practically all its nitrogen in the form of ammonia, and at the same time yielded a form of producer gas, used for fuel, of very considerable value, so that the coal was in no way wasted in giving out the ammonia wanted for the process. Then Mond was struck with the wastefulness of burning this valuable gas in the common way, under steam boilers. He, therefore, proceeded to utilise the discovery made by Groves, of utilising the hydrogen and oxygen in galvanic batteries. He made batteries in which producer gas on one side and air on the other were made to yield up their energy as electromotor force. One difficulty was carbon monoxide, which destroyed the batteries. Mond therefore turned his attention to removing this substance and overcame all the difficulties, and, in conjunction with Langer and Quincke, made one of the most remarkable discoveries, that of nickel carbonyl. He adapted this discovery to another industry, and invented a new metallurgical process to make pure nickel. By Mond's work they were now able, with common salt, common air, and the gaseous product of the lime-kiln, to make soda with the expenditure of comparatively little labour and fuel. That was the magical dream, to the realisation of which he had alluded. Most unfortunately Dr. Mond was not able to be present; but he had written the following letter:—

"Wyfold Court, near Reading,
"July 6th, 1906.

"Dear Dr. Divers,—Up to this date I had hoped and wished fervently that I might be able to take part in the celebration of the Jubilee Meeting of the Society of Chemical Industry in Manchester in the company of many old friends, and to receive from your hands on this occasion the medal of the Society, a distinction which I value very highly, and am particularly proud of having conferred upon me by the Council of the Society at its Twenty-fifth Anniversary Meeting. To my great disappointment, however, my medical adviser decrees that I have not yet sufficiently recovered my energies to enable me to undertake next week a journey to Manchester, and so I must perforce submit.

"As I have been so intimately connected with the Society ever since its foundation, and for some time previously, and have been, during the whole time of its existence, a member of the Council in one capacity or another, I need not assure you that it is a real grief to me not to be present at the celebration of its Twenty-fifth Anniversary—an occasion of rejoicing to all who have, like myself, been connected with the foundation and with the development of the Society, and who have been witnesses of its wonderful growth and of the great services the Society has rendered to its members and the industrial world at large.

"While I cannot be with you at this Meeting, I hope that I may yet have the satisfaction of remaining a useful and active member of the Council of the Society during the second jubilee term of its existence.

"Believe me,
"Yours very sincerely.
"LUDWIG MOND."

The PRESIDENT asked Mr. Eustace Carey to take charge of the medal for Dr. Mond, and to tell him that at that public meeting he (Dr. Divers) had expressed the very great honour which he felt in having, as President, to present that medal to the most perfect example that he knew of the chemical technologist.

Mr. CAREY received the medal from the President's hands, remarking that he need not say how deeply he regretted, and he was sure they all shared in that regret, that Dr. Mond was not there that day. He had very great pleasure in receiving the medal on his behalf, and would endeavour to transmit to him the words to which the President had given expression respecting him.

Dr. D. B. HEWITT moved that Messrs. Miall, Wilkins, Randall, and Co. be re-elected as auditors, at a fee of £10 10s. This was formally seconded by Mr. F. SCUDDER, and carried unanimously.

AMENDMENT OF BY-LAWS.

Sir BOVERTON REDWOOD, alluding to certain proposed amendments of the By-laws, of which printed copies were before the meeting, said that the object of

the amendments was to extend the time in which members residing beyond the seas might send in their ballot lists. He moved the adoption of the alteration of the By-laws, of which notice had been given.

The motion was seconded by Mr. IVAN LEVINSTEIN, and the amendments were adopted.

PLACE OF NEXT ANNUAL MEETING.

Prof. P. F. FRANKLAND, F.R.S., said he had the honour to represent the Birmingham Section of the Society, and on their behalf to extend to the Society a cordial invitation that the Annual Meeting of the Society take place next year in Birmingham. It had met in many provincial towns, including Manchester, Bradford, and Nottingham, and they thought it was now time it should meet in Birmingham, the capital of the Midlands. It was quite unnecessary for him to enlarge on Birmingham; it was a city which need not hide its light under a bushel. It had been used by many societies, and he could assure the meeting that the Society would meet with a reception both warm and welcome. He had very great pleasure in putting it to the Society, that the Annual Meeting be held next year in Birmingham.

Mr. W. W. BUTLER seconded, and on the motion being put to the meeting, it was carried unanimously.

The PRESIDENT said that the next business was the very pleasant one of expressing their thanks to the authorities of Manchester for the use of the Municipal School of Technology for the purposes of their meeting. It was a great thing to find such a splendid palace devoted to the purposes of technology. They ought, therefore, to have very great pleasure in expressing to its representative their great satisfaction, and their hearty thanks for the hospitality of its halls. (Applause.)

Dr. J. LEWKOWITSCH said that he had very great pleasure in seconding the resolution which the President had put before them. He also referred to the magnificent laboratories which bade fair to fill the want of this country in technical education. He himself, as an old Manchester citizen, felt some pride as he saw the growth of that establishment with its splendid site and its glorious laboratories, and thus Manchester had set an example to London, which was now contemplating the establishment of a similar institution. They had there an example of the old saying that what Lancashire did to-day, London and England would do to-morrow.

The vote was unanimously carried with acclamation, and the members then adjourned.

VISITS TO WORKS AND PLACES OF LOCAL INTEREST.

FIRST DAY.—WEDNESDAY, JULY 11TH.

MANCHESTER MUNICIPAL SCHOOL OF TECHNOLOGY.

This institution, with its bleaching, dyeing, printing, and finishing school for textile goods, and for paper-making, is a product of the enterprise of the Manchester Corporation, and of the development in the city, under its auspices, of technical instruction. The school is designed to accommodate the mechanical, electrical and sanitary engineering industries, the chemical and textile industries, architecture and the building trades, printing, and other less important trades and industries. The value of the sites, structures, and equipment of the two buildings exceeds £300,000. The Corporation owe the admirable site on which the school is placed to the liberality of the legatees of Sir Joseph Whitworth, Bart., who also added a gift of £5,000 towards the equipment. In addition, a sum of nearly £14,000 was received from the profits of the Royal Jubilee Exhibition of 1887.

On the left of the main entrance are the administrative offices, comprising the general office, the principal's rooms, and the council chamber, the remainder of the ground floor being allotted to the various classrooms and laboratories connected with the physics and textile departments. On the first floor is the large central hall for examinations or public lectures, and adjoining it are the library and reading rooms, a room for scientific societies' meetings, laboratories, class and lecture rooms for mathematics, and for electrical, mechanical and sanitary engineering. The second floor contains lecture rooms, drawing offices, and laboratories in connection with engineering, architecture and the building trades, the photographic and printing crafts, and electrical engineering. An experimental bakery is also placed on this floor. The organic and inorganic chemical laboratories, the principal chemical lecture theatre, laboratories for metallurgy and brewing, and the woodworking, plumbing and sanitary engineering workshops are placed upon the third floor. On the fourth floor are arranged the dyeing laboratories, an experimental brew-house, a gymnasium, a house painting and decorating workshop, and rooms for bookbinding and lithographic drawing. The astronomical observatory, situated above the fourth floor at the north-east corner of the building, is equipped with an equatorial telescope. The basement is covered by the workshops and laboratories for spinning and weaving, and for mechanical and electrical engineering, including laboratories for experimental motors and dynamos, steam and gas engines, hydraulic appliances, and the testing of materials.

The building in which is installed the department for the bleaching, dyeing, printing, and finishing of textile goods, and for the manufacture, dyeing and finishing of paper, is erected on a plot of land contiguous to the main building. In addition to containing technical laboratories, it is equipped with an extensive experimental plant.

The day departments of the school now form the Faculty of Technology of the University of Manchester, and students may prepare for the degrees of Bachelor and Master of Technical Science (B.Sc.Tech. and M.Sc.Tech.). The school is attended by upwards of 5,500 day and evening students. The principal of the school and Dean of the Faculty is Mr. J. H. Reynolds, M.Sc.

PILKINGTON'S TILE AND POTTERY CO., LTD., CLIFTON JUNCTION.

Leader: Mr. WILLIAM BURTON.

Here the manufacture of tiles of every description, from plain floor tiles of red, buff, or drab clay, to artistic hand-painted tiles for walls, fireplaces, or furniture, is carried out. Ceramic, mosaic, and architectural faïence are also largely manufactured, and during the last three years the Lancastrian pottery, representing the latest achievements of scientific glaze-making, has also been produced. During the last six months an entirely novel style of decoration has been introduced in the form of Lancastrian "Lustre Ware," which rivals the finest lustre wares of the ancient Persian, Spanish-Moorish, and Italian potters.

The following processes were shown and explained:—(1) The preparation and mixing of the primary materials, clays, flint, pegmatite, felspar, &c., used in the various bodies or pastes. (2) The preparation and mixing of the glazing and colouring materials. (3) The shaping of tiles, faïence, and vases: (*a*) tiles by compression of clay-dust; (*b*) faïence by pressing plastic clay in moulds; (*c*) vases, by throwing on the potter's wheel. (4) The firing of the clay into pottery. Various types of potters' ovens were shown, as well as the different pyrometers and pyroscopes used in controlling the firing. (5) The application of glaze to the fired pottery: (*a*) Dipping; (*b*) painting; (*c*) blowing by compressed air. (6) The firing of the glaze, together with the various precautions for obtaining the different colours. (7) The artists' departments, including modelling, designing, and painting.

Afternoon tea was provided for the visitors, and ere leaving a vote of thanks was proposed by Mr. Thos. Tyrer, to the firm, and especially to its director and manager, Mr. W. Burton, for his specially lucid explanatory remarks and demonstrations.

CALICO PRINTING WORKS OF MESSRS. SALIS SCHWABE AND CO., RHODES, NEAR MIDDLETON.

Leader: Dr. J. BÜRGER.

The operations carried on at these works include the bleaching, mercerising, printing, dyeing, and finishing of

cotton piece goods. The cloth to be printed arrives at the works in the grey state, just as it leaves the weaving shop. It contains the natural impurity of the cotton and the "size" added for weaving purposes. The first operation, that of bleaching, is to remove these natural and added impurities. The cloth, in the roll form, is subjected to the action, first, of lime, and afterwards of alkalis and resin, under steam pressure in closed keirs. It is afterwards treated with acid and bleaching liquor. The cloth, after washing, opening out, and drying, is ready for printing. The colours printed may either contain both the colouring matter and the mordant, which is used along with it to effect its fixation; or the mordant alone may in some cases be printed first, the colour being fixed upon the mordant by a subsequent dyeing operation. In the former case the cloth containing colour and mordant is submitted to the operation of steaming, by which the colour is fixed upon the fibre. In the latter case the mordant itself is fixed by a process of "ageing"—that is, by exposure to warm moist air or steam; the cloth is subsequently dyed in a solution of the colouring matter, the combination of mordant and colour being completed by a final steaming, as in the case of direct-printed goods.

The cloth is then subjected to cleansing or soaping operations to remove the excess of colour not fixed in the fibre, and so render the colour bright, and also fast against subsequent washing operations. After this the goods are finished and made up for delivery. The operations at the works also include that of mercerising. The engraving department of the works for the preparation of the copper rollers includes a plant for the electro deposition of copper on iron shells for the purpose of making engraving rollers less costly than those made entirely of copper. A plant for the manufacture of caustic soda, and its concentration by means of multiple-effect evaporators, is included in the works' equipment.

Reception at the Town Hall.

In the evening, the Lord Mayor (the Right Hon. James Herbert Thewlis) and the Lady Mayoress held a reception and conversazione at the Town Hall, at which nearly 600 people were present. The band of the 2nd V.B. Manchester Regiment was in attendance. Around the large hall are the remarkable frescoes illustrative of the city's history, painted by Ford Madox Brown. One represents John Dalton collecting marsh gas.

Second Day.—Thursday, July 12th.

Works of Messrs. Joseph Crosfield and Sons, Ltd., Warrington.

Leaders:—Messrs. J. J. Crosfield, Captain Crosfield, and Dr. K. Markel.

About 300 members of the Society paid a visit to the extensive works of this firm, which was founded by Mr. Joseph Crosfield in 1815.

This party, which contained many ladies, was conveyed, in omnibuses provided by Messrs. Crosfield, to their works at Bank Quay. The following are the chief products manufactured, and the demonstration of the various branches involved was most carefully and elaborately given by the leaders of the several parties.

Soaps.—"Perfection," "Pink Carbolic," and household, laundry, textile and other manufacturing soaps.

Carbosil.—A detergent and water softener, consisting of a double salt of sodium carbonate and silicate, said to combine the advantages of these two detergents without the disadvantages of either.

Erasmic toilet specialities and toilet soaps, &c.

Glycerine.—Crude, 80 per cent.; dynamite, and chemically pure 1·260 S.G.

Caustic soda.—Solid 77—78 per cent.; also powdered, stick, detached, and flaked caustic of the highest purity, and pure caustic liquor of 90° Tw.

Silicate of soda.—Alkaline and neutral lump, and solution in concentration varying from 75° Tw. to 175° Tw.

Speciality.—Water-glass for egg preserving.

Boiler fluid, disinfectant powder, protective paint and black enamel for ironwork, joint box composition for electrical insulation, "Veberine," a pure neutral sterilised vegetable butter.

Tin box making department.—The autogenous soldering of iron was illustrated, and excited considerable interest.

Caustic Soda.

There are two processes in use for the manufacture of caustic soda, the ordinary or lime process, and the Loewig or ferrite process. The former involves the production of a large amount of waste calcium carbonate, for the utilisation of which cement works are in process of construction on the other bank of the Mersey. In the ferrite process, iron oxide or "blue billy" and soda ash are mixed, and heated in a gas-fired revolving furnace for several hours; carbon dioxide is given off and sodium ferrite is produced, which is treated with water in lixiviating tanks, producing a solution of caustic soda of high strength. The ferric oxide thus recovered is used again with fresh soda ash.

A scheme was distributed amongst the visitors, illustrating the manufacture in the various stages, of soap, caustic soda and glycerine.

The firm provided a sumptuous dinner at mid-day, Dr. Markel presiding, and the works orchestra, conducted by Mr. F. H. Crossley, performed a selection of music during its progress.

The President proposed a hearty vote of thanks to Messrs. Crosfield for their exceeding hospitality, and for the kind manner in which the members had been conducted through these marvellous works. The vote was acknowledged by Dr. K. Markel, for the firm.

Not the least attractive demonstration was that following the dinner, *viz.*, the fire brigade and ambulance performances. The large engine sends out 750 galls. of water per minute, and is said to be the highest jet in Lancashire. The drill by a squad of the works volunteer company, and the gymnastic display by the girls, stimulated much interest. Performances were also given by the works brass band, and also by the male voice and mixed voice choirs. Later on in the afternoon, and before leaving, the visitors were entertained to tea in the fine roof-garden.

East Lancashire Paper Mill Co., Ltd., Radcliffe.

Leader: Mr. J. H. Lester.
